It is helpful to remember that the element  $p_{ij}$  is formed from the  $i$ th row of the first matrix and the  $j$ th column of the second matrix. The matrix product is not commutative. That is,  $AB \neq BA$  in general.

**Inverse of a Matrix** A square matrix  $A$  is said to have an inverse if there exists a matrix  $B$  such that  $AB = BA = I$ , where  $I$  is the identity matrix of order  $n$ .

$$\begin{bmatrix} 1 & 0 & \cdots & 0 \\ & 1 & & \\ & & \ddots & \\ 0 & \cdots & 0 & 1 \end{bmatrix}$$

The inverse  $B$  is a square matrix of the order of  $A$ , designated by  $A^{-1}$ . Thus  $AA^{-1} = A^{-1}A = I$ . A square matrix  $A$  has an inverse if and only if  $A$  is nonsingular.

Certain relations are important:

- (1)  $(AB)^{-1} = B^{-1}A^{-1}$
- (2)  $(AB)^T = B^T A^T$
- (3)  $(A^{-1})^T = (A^T)^{-1}$
- (4)  $(ABC)^{-1} = C^{-1}B^{-1}A^{-1}$

**Scalar Multiplication** Let  $c$  be any real or complex number. Then  $cA = (ca_{ij})$ .

**Adjugate Matrix of a Matrix** Let  $A_{ij}$  denote the cofactor of the element  $a_{ij}$  in the determinant of the matrix  $A$ . The matrix  $B^T$  where  $B = (A_{ij})$  is called the adjugate matrix of  $A$  written  $\text{adj } A = B^T$ . The elements  $b_{ij}$  are calculated by taking the matrix  $A$ , deleting the  $i$ th row and  $j$ th column, and calculating the determinant of the remaining matrix times  $(-1)^{i+j}$ . Then  $A^{-1} = \text{adj } A / |A|$ . This definition may be used to calculate  $A^{-1}$ . However, it is very laborious and the inversion is usually accomplished by numerical techniques shown under "Numerical Analysis and Approximate Methods."

**Linear Equations in Matrix Form** Every set of  $n$  nonhomogeneous linear equations in  $n$  unknowns

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n &= b_1 \\ a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n &= b_2 \\ \vdots & \vdots \\ a_{n1}x_1 + a_{n2}x_2 + \cdots + a_{nn}x_n &= b_n \end{aligned}$$

can be written in matrix form as  $AX = B$ , where  $A = (a_{ij})$ ,  $X^T = [x_1 \cdots x_n]$ , and  $B^T = [b_1 \cdots b_n]$ . The solution for the unknowns is  $X = A^{-1}B$ .

#### Special Square Matrices

1. A triangular matrix is a matrix all of whose elements above or below the main diagonal (set of elements  $a_{11}, \dots, a_{nn}$ ) are zero.

If  $A$  is triangular,  $\det(A) = a_{11} a_{22} \cdots a_{nn}$ .

2. A diagonal matrix is one such that all elements both above and below the main diagonal are zero (i.e.,  $a_{ij} = 0$  for all  $i \neq j$ ). If all diagonal elements are equal, the matrix is called scalar. If  $A$  is diagonal,  $A = (a_{ij})$ ,  $A^{-1} = (1/a_{ij})$ .

3. If  $a_{ij} = a_{ji}$  for all  $i$  and  $j$  (i.e.,  $A = A^T$ ), the matrix is symmetric.

4. If  $a_{ij} = -a_{ji}$  for  $i \neq j$  but the  $a_{ij}$  are not all zero, the matrix is skew.

5. If  $a_{ij} = -a_{ji}$  for all  $i$  and  $j$  (i.e.,  $a_{ii} = 0$ ), the matrix is skew symmetric.

6. If  $A^T = A^{-1}$ , the matrix  $A$  is orthogonal.

7. If the matrix  $A^{\circ} = (\bar{a}_{ij})^T$ ,  $\bar{a}_{ij}$  = complex conjugate of  $a_{ij}$ ,  $A^{\circ}$  is the hermitian transpose of  $A$ .

8. If  $A = A^{-1}$ ,  $A$  is involutory.

9. If  $A = A^{\circ}$ ,  $A$  is hermitian.

10. If  $A = -A^{\circ}$ ,  $A$  is skew hermitian.

11. If  $A^{-1} = A^{\circ}$ ,  $A$  is unitary.

If  $A$  is any matrix, then  $AA^T$  and  $A^T A$  are square symmetric matrices, usually of different order.

**Example** Let  $A = \begin{bmatrix} 5 & 1 & 3 & 0 \\ 3 & 4 & 1 & 5 \\ 2 & -2 & 0 & 1 \end{bmatrix}$ ,  $A^T = \begin{bmatrix} 5 & 3 & 2 \\ 1 & 4 & -2 \\ 3 & 1 & 0 \\ 0 & 5 & 1 \end{bmatrix}$

$$AA^T = \begin{bmatrix} 35 & 22 & 8 \\ 22 & 51 & 3 \\ 8 & 3 & 9 \end{bmatrix}, \quad A^T A = \begin{bmatrix} 38 & 13 & 18 & 17 \\ 13 & 21 & 7 & 18 \\ 18 & 7 & 10 & 5 \\ 17 & 18 & 5 & 26 \end{bmatrix}$$

Using a program such as MATLAB, these are easily calculated.

**Matrix Calculus**

**Differentiation** Let the elements of  $A = [a_{ij}(t)]$  be differentiable functions of  $t$ . Then  $\frac{dA}{dt} = \left[ \frac{da_{ij}(t)}{dt} \right]$ .

**Example**  $A = \begin{bmatrix} \sin t & \cos t \\ -\cos t & \sin t \end{bmatrix}$ ,  $\frac{dA}{dt} = \begin{bmatrix} \cos t & -\sin t \\ \sin t & \cos t \end{bmatrix}$ .

**Integration** The integral  $\int A dt = [\int a_{ij}(t) dt]$ .

**Example**  $A = \begin{bmatrix} t & 2 \\ t^2 & e^t \end{bmatrix}$ ,  $\int A dt = \begin{bmatrix} t^2/2 & 2t \\ t^3/3 & e^t \end{bmatrix}$ .

The matrix  $B = A - \lambda I$  is called the characteristic (eigen) matrix of  $A$ . Here  $A$  is square of order  $n$ ,  $\lambda$  is a scalar parameter, and  $I$  is the  $n \times n$  identity.  $\det B = \det (A - \lambda I) = 0$  is the characteristic (eigen) equation for  $A$ . The characteristic equation is always of the same degree as the order of  $A$ . The roots of the characteristic equation are called the eigenvalues of  $A$ .

**Example**  $A = \begin{bmatrix} 1 & 2 \\ 3 & 8 \end{bmatrix}$ ,  $B = \begin{bmatrix} 1-\lambda & 2 \\ 3 & 8-\lambda \end{bmatrix} = \begin{bmatrix} 1-\lambda & 2 \\ 3 & 8-\lambda \end{bmatrix}$

is the characteristic matrix and  $f(\lambda) = \det (B) = \det (A - \lambda I) = (1 - \lambda)(8 - \lambda) - 6 = 2 - 9\lambda + \lambda^2 = 0$  is the characteristic equation. The eigenvalues of  $A$  are the roots of  $\lambda^2 - 9\lambda + 2 = 0$ , which are  $(9 \pm \sqrt{73})/2$ .

A nonzero matrix  $X_i$ , which has one column and  $n$  rows, called a column vector satisfying the equation

$$(A - \lambda I)X_i = 0$$

and associated with the  $i$ th characteristic root  $\lambda_i$  is called an eigenvector.

**Vector and Matrix Norms** To carry out error analysis for approximate and iterative methods for the solutions of linear systems, one needs notions for vectors in  $R^n$  and for matrices that are analogous to the notion of length of a geometric vector. Let  $R^n$  denote the set of all vectors with  $n$  components,  $x = (x_1, \dots, x_n)$ . In dealing with matrices it is convenient to treat vectors in  $R^n$  as columns, and so  $x = (x_1, \dots, x_n)^T$ ; however, we shall here write them simply as row vectors. A norm on  $R^n$  is a real-valued function  $f$  defined on  $R^n$  with the following properties:

1.  $f(x) \geq 0$  for all  $x \in R^n$ .
2.  $f(x) = 0$  if and only if  $x = (0, 0, \dots, 0)$ .
3.  $f(ax) = |a|f(x)$  for all real numbers  $a$  and  $x \in R^n$ .
4.  $f(x + y) \leq f(x) + f(y)$  for all  $x, y \in R^n$ .

The usual notation for a norm is  $f(x) = \|x\|$ .

The norm of a matrix is

$$\kappa(A) \equiv \|A\| \|A^{-1}\|$$

where 
$$\|A\| = \sup_{x \neq 0} \frac{\|Ax\|}{\|x\|} = \max_k \sum_{j=1}^n |a_{jk}|$$

The norm is useful when doing numerical calculations. If the computer's floating-point precision is  $10^{-6}$ , then  $\kappa = 10^6$  indicates an ill-conditioned matrix. If the floating-point precision is  $10^{-12}$  (double precision), then a matrix with  $\kappa = 10^{12}$  may be ill-conditioned. Two other measures are useful and are more easily calculated:

$$\text{Ratio} = \frac{\max_k |a_{kk}^{(k)}|}{\min_k |a_{kk}^{(k)}|}, \quad V = \frac{|\det A|}{\alpha_1 \alpha_2 \dots \alpha_n}, \quad \alpha_i = (a_{i1}^2 + a_{i2}^2 + \dots + a_{in}^2)^{1/2}$$

where  $a_{kk}^{(k)}$  are the diagonal elements of the  $LU$  decomposition.

**MATRIX COMPUTATIONS**

The principal topics in linear algebra involve systems of linear equations, matrices, vector spaces, linear transformations, eigenvalues and eigenvectors, and least-squares problems. The calculations are routinely done on a computer.

**LU Factorization of a Matrix** To every  $m \times n$  matrix  $A$  there exists a permutation matrix  $P$ , a lower triangular matrix  $L$  with unit diagonal elements, and an  $m \times n$  (upper triangular) echelon matrix  $U$  such that  $PA = LU$ . The Gauss elimination is in essence an algorithm to determine  $U$ ,  $P$ , and  $L$ . The permutation matrix  $P$  may be needed since it may be necessary in carrying out the Gauss elimination to interchange two rows of  $A$  to produce a (nonzero) pivot, such as if we start with

$$A = \begin{bmatrix} 0 & 2 \\ 1 & 6 \end{bmatrix}$$

If  $A$  is a square matrix and if principal submatrices of  $A$  are all nonsingular, then we may choose  $P$  as the identity in the preceding factorization and obtain  $A = LU$ . This factorization is unique if  $L$  is normalized (as assumed previously), so that it has unit elements on the main diagonal.

**Solution of  $Ax = b$  by Using LU Factorization** Suppose that the indicated system is compatible and that  $A = LU$  (the case  $PA = LU$  is similarly handled and amounts to rearranging the equations). Let  $z = Ux$ . Then  $Ax = LUx = b$  implies that  $Lz = b$ . Thus to solve  $Ax = b$  we first solve  $Lz = b$  for  $z$  and then solve  $Ux = z$  for  $x$ . This procedure does not require that  $A$  be invertible and can be used to determine all solutions of a compatible system  $Ax = b$ . Note that the systems  $Lz = b$  and  $Ux = z$  are both in triangular forms and thus can be easily solved.

The  $LU$  decomposition is essentially a Gaussian elimination, arranged for maximum efficiency. The chief reason for doing an  $LU$  decomposition is that it takes fewer multiplications than would be needed to find an inverse. Also, once the  $LU$  decomposition has been found, it is possible to solve for multiple right-hand sides with little increase in work. The multiplication count for an  $n \times n$  matrix and  $m$  right-hand sides is

$$\text{operation count} = \frac{1}{3} n^3 - \frac{1}{3} n + mn^2$$

If an inverse is desired, it can be calculated by solving for the  $LU$  decomposition and then solving  $n$  problems with right-hand sides consisting of all zeros except one entry. Thus  $4n^2/3 - n/3$  multiplications are required for the inverse. The determinant is given by

$$\text{Det } A = \prod_{i=1}^n a_{ii}^{(i)}$$

where  $a_{ii}^{(i)}$  are the diagonal elements obtained in the  $LU$  decomposition.

A tridiagonal matrix is one in which the only nonzero entries lie on the main diagonal and the diagonal just above and just below the main diagonal. The set of equations can be written as

$$a_i x_{i-1} + b_i x_i + c_i x_{i+1} = d_i$$

The  $LU$  decomposition is

$$b_1 = b_1$$

for  $k=2, n$  do

$$a'_k = \frac{a_k}{b'_{k-1}}, \quad b'_k = b_k - \frac{a_k}{b'_{k-1}} c_{k-1}$$

enddo

$$d'_1 = d_1$$

for  $k=2, n$  do

$$d'_k = d_k - a'_k d'_{k-1}$$

enddo

$$x_n = d'_n / b'_n$$

for  $k=n-1, 1$  do

$$x_k = \frac{d'_k - c_k x_{k+1}}{b'_k}$$

enddo

The operation count for an  $n \times n$  matrix with  $m$  right-hand sides is

$$2(n - 1) + m(3n - 2)$$

If  $|b_i| > |a_i| + |c_i|$

no pivoting is necessary, and this is true for many boundary-value problems and partial-differential equations.

Sparse matrices are ones in which the majority of the elements are zero. If the structure of the matrix is exploited, the solution time on a computer is greatly reduced. See Duff, I. S., J. K. Reid, and A. M. Erisman (eds.), *Direct Methods for Sparse Matrices*, Clarendon Press, Oxford (1986); Saad, Y., *Iterative Methods for Sparse Linear Systems*, 2d ed., Society for Industrial and Applied Mathematics, Philadelphia (2003). The conjugate gradient method is one method for solving sparse matrix problems, since it only involves multiplication of a matrix times a vector. Thus the sparseness of the matrix is easy to exploit. The conjugate gradient method is an iterative method that converges for sure in  $n$  iterations where the matrix is an  $n \times n$  matrix.

Matrix methods, in particular finding the rank of the matrix, can be used to find the number of independent reactions in a reaction set. If the stoichiometric numbers for the reactions and molecules are put in the form of a matrix, the rank of the matrix gives the number of independent reactions. See Amundson, N. R., *Mathematical Methods in Chemical Engineering*, Prentice-Hall, Englewood Cliffs, N.J. (1966, p. 50).

**QR Factorization of a Matrix** If  $A$  is an  $m \times n$  matrix with  $m \geq n$ , there exists an  $m \times m$  unitary matrix  $Q = [q_1, q_2, \dots, q_m]$  and an  $m \times n$  right triangular matrix  $R$  such that  $A = QR$ . The  $QR$  factorization is frequently used in the actual computations when the other transformations are unstable.

**Singular-Value Decomposition** If  $A$  is an  $m \times n$  matrix with  $m \geq n$  and rank  $k \leq n$ , consider the two following matrices.

$$AA^o \text{ and } A^oA$$

An  $m \times m$  unitary matrix  $U$  is formed from the eigenvectors  $u_i$  of the first matrix.

$$U = [u_1, u_2, \dots, u_m]$$

An  $n \times n$  unitary matrix  $V$  is formed from the eigenvectors  $v_i$  of the second matrix.

$$V = [v_1, v_2, \dots, v_n]$$

Then matrix  $A$  can be decomposed into

$$A = U\Sigma V^o$$

where  $\Sigma$  is a  $k \times k$  diagonal matrix with diagonal elements  $d_{ii} = \sigma_i > 0$  for  $1 \leq i \leq k$ . The eigenvalues of  $\Sigma^T\Sigma$  are  $\sigma_i^2$ . The vectors  $u_i$  for  $k + 1 \leq i \leq m$  and  $v_i$  for  $k + 1 \leq i \leq n$  are eigenvectors associated with the eigenvalue zero; the eigenvalues for  $1 \leq i \leq k$  are  $\sigma_i^2$ . The values of  $\sigma_i$  are called the singular values of matrix  $A$ . If  $A$  is real, then  $U$  and  $V$  are real and hence orthogonal matrices. The value of the singular-value decomposition comes when a process is represented by a linear transformation and the elements of  $A$ ,  $a_{ij}$ , are the contribution to an output  $i$  for a particular variable as input variable  $j$ . The input may be the size of a disturbance, and the output is the gain [Seborg, D. E., T. F. Edgar, and D. A. Mellichamp, *Process Dynamics and Control*, 2d ed., Wiley, New York (2004)]. If the rank is less than  $n$ , not all the variables are independent and they cannot all be controlled. Furthermore, if the singular values are widely separated, the process is sensitive to small changes in the elements of the matrix, and the process will be difficult to control.

**Example** Consider the following example from Noble and Daniel [*Applied Linear Algebra*, Prentice-Hall (1987)] with the MATLAB commands to do the analysis. Define the following real matrix with  $m = 3$  and  $n = 2$  (whose rank  $k = 1$ ).

```
>> a = [ 1 1
        2 2
        2 2]
```

```
>> a1 = a^o*a
a1 = 9 9 % (n x n or 2 x 2)
     9 9
>> a2 = a^o*a'
a2 = 2 4 4 % (m x m or 3 x 3)
     4 8 8
     4 8 8
>> [v,d1]=eig(a1)
v = -0.7071 0.7071 % (n x n or 2 x 2)
     0.7071 0.7071
d1 = 0 0
     0 18
>> [u,d2]=eig(a2)
u = 0.8944 0.2981 0.3333 % (m x m or 3 x 3)
    -0.4472 0.5963 0.6667
     0 -0.7454 0.6667
d2 = 0 0 0
     0 0 0
     0 0 18
```

Thus,  $\sigma_1^2 = 18$  and the eigenfunctions are the rows of  $v$  and  $u$ . The second column of  $v$  is associated with the eigenvalue  $\sigma_1^2 = 18$ , and the third column of  $u$  is associated with the eigenvalue  $\sigma_1^2 = 18$ .

If  $A$  is square and nonsingular, the vector  $x$  that minimizes

$$\|Ax - b\| \tag{3-71}$$

is obtained by solving the linear equations

$$x = A^{-1}b$$

When  $A$  is not square, then the solution to

$$Ax = b$$

is

$$x = Vy$$

where  $y_i = b'_i/\sigma_i$  for  $i = 1, \dots, k$ ,  $b' = U^Tb$ , and  $y_{k+1}, y_{k+2}, \dots, y_m$  are arbitrary. The matrices  $U$  and  $V$  are those obtained in the singular-value decomposition. The solution which minimizes the norm, Eq. (3-71), is  $x$  with  $y_{k+1}, y_{k+2}, \dots, y_m$  zero. These techniques can be used to monitor process variables. See Montgomery, D. C., *Introduction to Statistical Quality Control*, 4th ed., Wiley, New York (2001); Piovos, M. J., and K. A. Hoo, "Multivariate Statistics for Process Control," *IEEE Control Systems* **22**(5):8 (2002).

**Principal Component Analysis (PCA)** PCA is used to recognize patterns in data and reduce the dimensionality of the problem. Let the matrix  $A$  now represent data with the columns of  $A$  representing different samples and the rows representing different variables. The covariance matrix is defined as

$$\text{cov}(A) = \frac{A^T A}{m - 1}$$

This is just the same matrix discussed with singular value decomposition. For data analysis, though, it is necessary to adjust the columns to have zero mean by subtracting from each entry in the column the average of the column entries. Once this is done, the *loadings* are the  $v_i$  and satisfy

$$\text{cov}(A) v_i = \sigma_i^2 v_i$$

and the *score* vector  $u_i$  is given by

$$A v_i = \sigma_i u_i$$

In process analysis, the columns of  $A$  represent different measurement techniques (temperatures, pressures, etc.) and the rows represent the measurement output at different times. In that case

the columns of  $A$  are adjusted to have a zero mean and a variance of 1.0 (by dividing each entry in the column by the variance of the column). The goal is to represent the essential variation of the process with as few variables as possible. The  $\mathbf{u}_i, \mathbf{v}_i$  pairs are arranged in descending order according to the associated  $\sigma_i$ . The  $\sigma_i$  can be thought of as the variance, and the  $\mathbf{u}_i, \mathbf{v}_i$  pair captures the greatest amount of variation in the data. Instead of having to deal with  $n$  variables, one can capture most of the variation of the

data by using only the first few pairs. An excellent example of this is given by Wise, B. M., and B. R. Kowalski, "Process Chemometrics," Chap. 8 in *Process Analytical Chemistry*, F. McLennan and B. Kowalski (eds.), Blackie Academic & Professional, London (1995). When modeling a slurry-fed ceramic melter, they were able to capture 97 percent of the variation by using only four eigenvalues and eigenvectors, even though there were 16 variables (columns) measured.

NUMERICAL APPROXIMATIONS TO SOME EXPRESSIONS

APPROXIMATION IDENTITIES

For the following relationships the sign  $\cong$  means approximately equal to, when  $X$  is small. These equations are derived by using a Taylor's series (see "Series Summation and Identities").

| Approximation                     | Approximation                            |
|-----------------------------------|--|
| $\frac{1}{1 \pm X} \cong 1 \mp X$ | $\sqrt{1 \pm X} \cong 1 \pm \frac{X}{2}$ |

| Approximation                            | Approximation  |
|--|--|
| $(1 \pm X)^n \cong 1 \pm nX$             | $(1 \pm X)^{-n} \cong 1 \mp nX$  |
| $(a \pm X)^2 \cong a^2 \pm 2aX$          | $e^x \cong 1 + X$  |
| $\sin X \cong X(X \text{ rad})$          | $\tan X \cong X$   |
| $\sqrt{Y(Y + X)} \cong \frac{2Y + X}{2}$ | $\sqrt{Y^2 + X^2} \cong Y + \frac{X^2}{2Y} \left(\frac{X}{Y} \text{ small}\right)$ |

INTRODUCTION

The goal of approximate and numerical methods is to provide convenient techniques for obtaining useful information from mathematical formulations of physical problems. Often this mathematical statement is not solvable by analytical means. Or perhaps analytic solutions are available but in a form that is inconvenient for direct interpretation. In the first case it is necessary either to attempt to approximate the problem satisfactorily by one which will be amenable to analysis, to obtain an approximate solution to the original problem by numerical means, or to use the two techniques in combination.

Numerical techniques therefore do not yield exact results in the sense of the mathematician. Since most numerical calculations are inexact, the concept of error is an important feature. The error associated with an approximate value is defined as

$$\text{True value} = \text{approximate value} + \text{error}$$

The four sources of error are as follows:

1. *Gross errors.* These result from unpredictable human, mechanical, or electrical mistakes.
2. *Round-off errors.* These are the consequence of using a number specified by  $m$  correct digits to approximate a number which requires more than  $m$  digits for its exact specification. For example, approximate the irrational number  $\sqrt{2}$  by 1.414. Such errors are often present in experimental data, in which case they may be called inherent errors, due either to empiricism or to the fact that the computer dictates the number of digits. Such errors may be especially damaging in areas such as matrix inversion or the numerical solution of partial differential equations when the number of algebraic operations is extremely large.
3. *Truncation errors.* These errors arise from the substitution of a finite number of steps for an infinite sequence of steps which would yield the exact result. To illustrate this error consider the infinite series for  $e^{-x}$ :  $e^{-x} = 1 - x + x^2/2 - x^3/6 + E_T(x)$ , where  $E_T$  is the truncation error,  $E_T = (1/24)e^{-\epsilon}x^4$ ,  $0 < \epsilon < x$ . If  $x$  is positive,  $\epsilon$  is also positive. Hence  $e^{-\epsilon} < 1$ . The approximation  $e^{-x} \approx 1 - x + x^2/2 - x^3/6$  is in error by a positive amount smaller than  $(1/24)x^4$ .
4. *Inherited errors.* These arise as a result of errors occurring in the previous steps of the computational algorithm.

The study of errors in a computation is related to the theory of probability. In what follows a relation for the error will be given in certain instances.

A variety of general-purpose computer programs are available commercially. Mathematica (<http://www.wolfram.com/>), Maple (<http://www.maplesoft.com/>), and Mathcad (<http://www.mathcad.com/>) all have the capability of doing symbolic manipulation so that algebraic solutions can be obtained. For example, Mathematica can solve some ordinary and partial differential equations analytically; Maple can make simple graphs and do linear algebra and simple computations; and Mathcad can do simple calculations. In this section, examples are given for the use of Matlab (<http://www.mathworks.com/>), which is a package of numerical analysis tools, some of which are accessed by simple commands and others of which are accessed by writing programs in C. Spreadsheets can also be used to solve certain problems, and these are described below too. A popular program used in chemical engineering education is Polymath (<http://www.polymath-software.com/>), which can numerically solve sets of linear or nonlinear equations, ordinary differential equations as initial-value problems, and perform data analysis and regression.

**NUMERICAL SOLUTION OF LINEAR EQUATIONS**

See the section entitled “Matrix Algebra and Matrix Computation.”

**NUMERICAL SOLUTION OF NONLINEAR EQUATIONS IN ONE VARIABLE**

**Special Methods for Polynomials** Consider a polynomial equation of degree  $n$ :

$$P(x) = a_0x^n + a_1x^{n-1} + a_2x^{n-2} + \dots + a_{n-1}x + a_n = 0 \quad (3-72)$$

with real coefficients.  $P(x)$  has exactly  $n$  roots, which may be real or complex. If the roots are complex, they occur in pairs with their complex conjugates.

One can obtain an upper and lower bound for the real roots by the following device: If  $a_0 > 0$  in Eq. (3-72) and if in Eq. (3-72) the first negative coefficient is preceded by  $k$  coefficients which are positive or zero, and if  $G$  is the greatest of the absolute values of the negative coefficients, then each real root is less than  $1 + \sqrt[k]{G/a_0}$ .

**Example**  $P(x) = x^5 + 3x^4 - 7x^3 - 40x + 2 = 0$ . Here  $a_0 = 1$ ,  $G = 40$ , and  $k = 3$  since we must supply 0 as the coefficient for  $x^3$ . Thus  $1 + \sqrt[3]{40} \approx 4.42$  is an upper bound for the real roots. The largest real root is 2.19.

A lower bound to the real roots may be found by applying the criterion to the equation  $P(-x)$ .

**Example**  $P(-x) = -x^5 + 3x^4 - 7x^3 + 40x + 2 = 0$ , which is equivalent to  $x^5 - 3x^4 + 7x^3 - 40x - 2 = 0$  since  $a_0$  must be +. Then  $a_0 = 1$ ,  $G = 40$ , and  $k = 1$ . Hence  $-(1 + 40) = -41$  is a lower bound. The smallest real root is  $-3.41$ . Thus all real roots are between  $-41$  and  $4.42$ .

One last result is helpful in getting an estimate of how many positive and negative real roots there are.

**Descartes Rule** The number of positive real roots of a polynomial with real coefficients is either equal to the number of changes in sign  $v$  or is less than  $v$  by a positive even integer. The number of negative roots of  $P(x)$  is either equal to the number of variations of sign of  $P(-x)$  or is less than this by a positive even integer.

**Example**  $f(x) = x^4 - 13x^2 + 4x - 2 = 0$  has three changes in sign; therefore, there are either three or one positive root.  $f(-x) = x^4 - 13x^2 - 4x - 2$  has one change in sign. Therefore, there is one negative root. Using MATLAB, one defines the vector

$$C(i) = a_{i-1}$$

and uses the command roots(c) to find all the roots.

**Methods for Nonlinear Equations in One Variable**

**Successive Substitutions** Let  $f(x) = 0$  be the nonlinear equation to be solved. If this is rewritten as  $x = F(x)$ , then an iterative scheme can be set up in the form  $x_{k+1} = F(x_k)$ . To start the iteration an initial guess must be obtained graphically or otherwise. The convergence or divergence of the procedure depends upon the method of writing  $x = F(x)$ , of which there will usually be several forms. However, if  $a$  is a root of  $f(x) = 0$ , and if  $|F'(a)| < 1$ , then for any initial approximation sufficiently close to  $a$ , the method converges to  $a$ . This process is called first order because the error in  $x_{k+1}$  is proportional to the first power of the error in  $x_k$  for large  $k$ .

One way of writing the equation is  $x_{k+1} = x_k + \beta f(x_k)$ . The choice of  $\beta$  is made such that  $|1 + \beta df/dx(a)| < 1$ . Convergence is guaranteed by the theorem given for simultaneous equations.

**Methods of Perturbation** Let  $f(x) = 0$  be the equation. In general, the iterative relation is

$$x_{k+1} = x_k - [f(x_k)/\alpha_k]$$

where the iteration begins with  $x_0$  as an initial approximation and  $\alpha_k$  as some functional, derived below.

**Newton-Raphson Procedure** This variant chooses  $\alpha_k = f'(x_k)$  where  $f' = df/dx$  and geometrically consists of replacing the graph of

$f(x)$  by the tangent line at  $x = x_k$  in each successive step. If  $f'(x)$  and  $f''(x)$  have the same sign throughout an interval  $a \leq x \leq b$  containing the solution, with  $f(a), f(b)$  of opposite signs, then the process converges starting from any  $x_0$  in the interval  $a \leq x \leq b$ . The process is second order.

**Example**  $f(x) = x - 1 + \frac{(0.5)^x - 0.5}{0.3}$

$$f'(x) = 1 - 2.3105[0.5]^x$$

An approximate root (obtained graphically) is 2.

| Step $k$ | $x_k$  | $f(x_k)$ | $f'(x_k)$ |
|----------|--------|----------|-----------|
| 0        | 2      | 0.1667   | 0.4224    |
| 1        | 1.6054 | 0.0342   | 0.2407    |
| 2        | 1.4632 | 0.0055   | 0.1620    |

**Method of False Position** This variant is commenced by finding  $x_0$  and  $x_1$  such that  $f(x_0), f(x_1)$  are of opposite signs. Then  $\alpha_1 =$  slope of secant line joining  $[x_0, f(x_0)]$  and  $[x_1, f(x_1)]$  so that

$$x_2 = x_1 - \frac{x_1 - x_0}{f(x_1) - f(x_0)} f(x_1)$$

In each of the following steps  $\alpha_k$  is the slope of the line joining  $[x_k, f(x_k)]$  to the most recently determined point where  $f(x_i)$  has the opposite sign from that of  $f(x_k)$ . This method is of first order. If one uses the most recently determined point (regardless of sign), the method is a secant method.

**Method of Wegstein** This is a variant of the method of successive substitutions which forces and/or accelerates convergence. The iterative procedure  $x_{k+1} = F(x_k)$  is revised by setting  $\hat{x}_{k+1} = F(x_k)$  and then taking  $x_{k+1} = qx_k + (1 - q)\hat{x}_{k+1}$ , where  $q$  is a suitably chosen number which may be taken as constant throughout or may be adjusted at each step. Wegstein found that suitable  $q$ 's are:

| Behavior of successive substitution process |                  | Range of optimum $q$ |
|---|------------------|----------------------|
| Oscillatory convergence                     |                  | $0 < q < 1/2$        |
| Oscillatory divergence                      | without Wegstein | $1/2 < q < 1$        |
| Monotonic convergence                       |                  | $q < 0$              |
| Monotonic divergence                        | without Wegstein | $1 < q$              |

At each step  $q$  may be calculated to give a locally optimum value by setting

$$q = \frac{\hat{x}_{k+1} - \hat{x}_k}{\hat{x}_{k+1} - 2\hat{x}_k + \hat{x}_{k-1}}$$

The Wegstein method is a secant method applied to  $g(x) \equiv x - F(x)$ . In Microsoft Excel, roots are found by using Goal Seek or Solver. Assign one cell to be  $x$ , put the equation for  $f(x)$  in another cell, and let Goal Seek or Solver find the value of  $x$  that makes the equation cell zero. In MATLAB, the process is similar except that a function (m-file) is defined and the command fzero('f',x0) provides the solution  $x$ , starting from the initial guess  $x_0$ .

**METHODS FOR MULTIPLE NONLINEAR EQUATIONS**

**Method of Successive Substitutions** Write a system of equations as

$$\alpha_i = f_i(\alpha), \quad \text{or} \quad \alpha = f(\alpha)$$

The following theorem guarantees convergence. Let  $\alpha$  be the solution to  $\alpha_i = f_i(\alpha)$ . Assume that given  $h > 0$ , there exists a number  $0 < \mu < 1$  such that

$$\sum_{j=1}^n \left| \frac{\partial f_i}{\partial x_j} \right| \leq \mu \quad \text{for} \quad |x_i - \alpha_i| < h, \quad i = 1, \dots, n$$

$$x_i^{k+1} = f_i(x_i^k)$$

Then  $x_i^k \rightarrow \alpha_i$

as  $k$  increases [see Finlayson (2003)].

**Newton-Raphson Method** To solve the set of equations

$$F_i(x_1, x_2, \dots, x_n) = 0, \text{ or } F_i(\{x_j\}) = 0, \text{ or } F_i(\mathbf{x}) = 0$$

one uses a truncated Taylor series to give

$$0 = F_i(\{x^k\}) + \sum_{j=1}^n \frac{\partial F_i}{\partial x_j} \Big|_{x^k} (x_j^{k+1} - x_j^k)$$

Thus one solves iteratively from one point to another.

$$\sum_{j=1}^n A_{ij}^k (x_j^{k+1} - x_j^k) = -F_i(\{x^k\})$$

where

$$A_{ij}^k = \frac{\partial F_i}{\partial x_j} \Big|_{x^k}$$

This method requires solution of sets of linear equations until the functions are zero to some tolerance or the changes of the solution between iterations is small enough. Convergence is guaranteed provided the norm of the matrix **A** is bounded, **F(x)** is bounded for the initial guess, and the second derivative of **F(x)** with respect to all variables is bounded. See Finlayson (2003).

**Method of Continuity (Homotopy)** In the case of *n* equations in *n* unknowns, when *n* is large, determining the approximate solution may involve considerable effort. In such a case the method of continuity is admirably suited for use on digital computers. It consists basically of the introduction of an extra variable into the *n* equations

$$f_i(x_1, x_2, \dots, x_n) = 0 \quad i = 1, \dots, n \quad (3-73)$$

and replacing them by

$$f_i(x_1, x_2, \dots, x_n, \lambda) = 0 \quad i = 1, \dots, n \quad (3-74)$$

where  $\lambda$  is introduced in such a way that the functions (3-74) depend in a simple way upon  $\lambda$  and reduce to an easily solvable system for  $\lambda = 0$  and to the original equations (3-73) for  $\lambda = 1$ . A system of ordinary differential equations, with independent variable  $\lambda$ , is then constructed by differentiating Eqs. (3-74) with respect to  $\lambda$ . There results

$$\sum_{j=1}^n \frac{\partial f_i}{\partial x_j} \frac{dx_j}{d\lambda} + \frac{\partial f_i}{\partial \lambda} = 0 \quad (3-75)$$

where  $x_1, \dots, x_n$  are considered as functions of  $\lambda$ . Equations (3-75) are integrated, with initial conditions obtained from Eqs. (3-74) with  $\lambda = 0$ , from  $\lambda = 0$  to  $\lambda = 1$ . If the solution can be continued to  $\lambda = 1$ , the values of  $x_1, \dots, x_n$  for  $\lambda = 1$  will be a solution of the original equations. If the integration becomes infinite, the parameter  $\lambda$  must be introduced in a different fashion. Integration of the differential equations (which are usually nonlinear in  $\lambda$ ) may be accomplished by using techniques described under "Numerical Solution of Ordinary Differential Equations."

**Other Methods** Other methods can be found in the literature. See Chan, T. F. C., and H. B. Keller, *SIAM J. Sci. Stat. Comput.* **3**:173-194 (1982); Seader, J. D., "Computer Modeling of Chemical Processes," *AIChE Monograph Series* **81**(15) (1986).

**INTERPOLATION AND FINITE DIFFERENCES**

**Linear Interpolation** If a function  $f(x)$  is approximately linear in a certain range, then the ratio

$$\frac{f(x_1) - f(x_0)}{x_1 - x_0} = f[x_0, x_1]$$

is approximately independent of  $x_0, x_1$  in the range. The linear approximation to the function  $f(x), x_0 < x < x_1$  then leads to the interpolation formula

$$\begin{aligned} f(x) &\approx f(x_0) + (x - x_0)f[x_0, x_1] \\ &\approx f(x_0) + \frac{x - x_0}{x_1 - x_0} [f(x_1) - f(x_0)] \\ &\approx \frac{1}{x_1 - x_0} [(x_1 - x)f(x_0) - (x_0 - x)f(x_1)] \end{aligned}$$

**Divided Differences of Higher Order and Higher-Order Interpolation** The first-order divided difference  $f[x_0, x_1]$  was defined previously. Divided differences of second and higher order are defined iteratively by

$$f[x_0, x_1, x_2] = \frac{f[x_1, x_2] - f[x_0, x_1]}{x_2 - x_0}$$

⋮

$$f[x_0, x_1, \dots, x_k] = \frac{f[x_1, \dots, x_k] - f[x_0, x_1, \dots, x_{k-1}]}{x_k - x_0}$$

and a convenient form for computational purposes is

$$f[x_0, x_1, \dots, x_k] = \sum_{j=0}^k \frac{f(x_j)}{(x_j - x_0)(x_j - x_1) \dots (x_j - x_k)}$$

for any  $k \geq 0$ , where the ' means that the term  $(x_j - x_j)$  is omitted in the denominator. For example,

$$f[x_0, x_1, x_2] = \frac{f(x_0)}{(x_0 - x_1)(x_0 - x_2)} + \frac{f(x_1)}{(x_1 - x_0)(x_1 - x_2)} + \frac{f(x_2)}{(x_2 - x_0)(x_2 - x_1)}$$

If the accuracy afforded by a linear approximation is inadequate, a generally more accurate result may be based upon the assumption that  $f(x)$  may be approximated by a polynomial of degree 2 or higher over certain ranges. This assumption leads to Newton's fundamental interpolation formula with divided differences

$$\begin{aligned} f(x) &\approx f(x_0) + (x - x_0)f[x_0, x_1] + (x - x_0)(x - x_1)f[x_0, x_1, x_2] \\ &\quad + \dots + (x - x_0)(x - x_1) \dots (x - x_{n-1})f[x_0, x_1, \dots, x_n] + E_n(x) \end{aligned}$$

where

$$E_n(x) = \text{error} = \frac{1}{(n + 1)!} f^{n+1}(\epsilon)\pi(x)$$

where minimum  $(x_0, \dots, x) < \epsilon < \text{maximum } (x_0, x_1, \dots, x_n, x)$  and  $\pi(x) = (x - x_0)(x - x_1) \dots (x - x_n)$ . In order to use the previous equation most effectively one may first form a divided-difference table. For example, for third-order interpolation the difference table is

|       |          |               |                    |                         |
|-------|----------|---------------|--------------------|-------------------------|
| $x_0$ | $f(x_0)$ | $f[x_0, x_1]$ | $f[x_0, x_1, x_2]$ | $f[x_0, x_1, x_2, x_3]$ |
| $x_1$ | $f(x_1)$ | $f[x_1, x_2]$ | $f[x_1, x_2, x_3]$ |                         |
| $x_2$ | $f(x_2)$ | $f[x_2, x_3]$ |                    |                         |
| $x_3$ | $f(x_3)$ |               |                    |                         |

where each entry is given by taking the difference between diagonally adjacent entries to the left, divided by the abscissas corresponding to the ordinates intercepted by the diagonals passing through the calculated entry.

**Equally Spaced Forward Differences** If the ordinates are equally spaced, i.e.,  $x_j - x_{j-1} = \Delta x$  for all *j*, then the first differences are denoted by  $\Delta f(x_0) = f(x_1) - f(x_0)$  or  $\Delta y_0 = y_1 - y_0$ , where  $y = f(x)$ . The differences of these first differences, called second differences, are denoted by  $\Delta^2 y_0, \Delta^2 y_1, \dots, \Delta^2 y_n$ . Thus

$$\Delta^2 y_0 = \Delta y_1 - \Delta y_0 = y_2 - y_1 - y_1 + y_0 = y_2 - 2y_1 + y_0$$

And in general

$$\Delta^j y_0 = \sum_{n=0}^j (-1)^n \binom{j}{n} y_{j-n}$$

where  $\binom{j}{n} = \frac{j!}{n!(j-n)!} = \text{binomial coefficients}$ .

If the ordinates are equally spaced,

$$\begin{aligned} x_{n+1} - x_n &= \Delta x \\ y_n &= y(x_n) \end{aligned}$$

then the first and second differences are denoted by

$$\begin{aligned} \Delta y_n &= y_{n+1} - y_n \\ \Delta^2 y_n &= \Delta y_{n+1} - \Delta y_n = y_{n+2} - 2y_{n+1} + y_n \end{aligned}$$

A new variable is defined

$$\alpha = \frac{x - x_0}{\Delta x}$$

and the finite interpolation formula through the points  $y_0, y_1, \dots, y_n$  is written as follows:

$$y_\alpha = y_0 + \alpha \Delta y_0 + \frac{\alpha(\alpha-1)}{2!} \Delta^2 y_0 + \dots + \frac{\alpha(\alpha-1) \dots (\alpha-n+1)}{n!} \Delta^n y_0 \tag{3-76}$$

Keeping only the first two terms gives a straight line through  $(x_0, y_0)$ – $(x_1, y_1)$ ; keeping the first three terms gives a quadratic function of position going through those points plus  $(x_2, y_2)$ . The value  $\alpha = 0$  gives  $x = x_0$ ;  $\alpha = 1$  gives  $x = x_1$ , and so on.

**Equally Spaced Backward Differences** Backward differences are defined by

$$\begin{aligned} \nabla y_n &= y_n - y_{n-1} \\ \nabla^2 y_n &= \nabla y_n - \nabla y_{n-1} = y_n - 2y_{n-1} + y_{n-2} \end{aligned}$$

The interpolation polynomial of order  $n$  through the points  $y_0, y_{-1}, \dots, y_{-n}$  is

$$y_\alpha = y_0 + \alpha \nabla y_0 + \frac{\alpha(\alpha+1)}{2!} \nabla^2 y_0 + \dots + \frac{\alpha(\alpha+1) \dots (\alpha+n-1)}{n!} \nabla^n y_0$$

The value of  $\alpha = 0$  gives  $x = x_0$ ;  $\alpha = -1$  gives  $x = x_{-1}$ , and so on. Alternatively, the interpolation polynomial of order  $n$  through the points  $y_1, y_0, y_{-1}, \dots, y_{-n}$  is

$$y_\alpha = y_1 + (\alpha-1) \nabla y_1 + \frac{\alpha(\alpha-1)}{2!} \nabla^2 y_1 + \dots + \frac{(\alpha-1) \alpha (\alpha+1) \dots (\alpha+n-2)}{n!} \nabla^n y_1 \tag{3-77}$$

Now  $\alpha = 1$  gives  $x = x_1$ ;  $\alpha = 0$  gives  $x = x_0$ .

**Central Differences** The central difference denoted by

$$\begin{aligned} \delta f(x) &= f\left(x + \frac{h}{2}\right) - f\left(x - \frac{h}{2}\right) \\ \delta^2 f(x) &= \delta f\left(x + \frac{h}{2}\right) - \delta f\left(x - \frac{h}{2}\right) = f(x+h) - 2f(x) + f(x-h) \\ \delta^n f(x) &= \delta^{n-1} f\left(x + \frac{h}{2}\right) - \delta^{n-1} f\left(x - \frac{h}{2}\right) \end{aligned}$$

is useful for calculating at the interior points of tabulated data.

**Lagrange Interpolation Formulas** A global polynomial is defined over the entire region of space

$$P_m(x) = \sum_{j=0}^m c_j x^j$$

This polynomial is of degree  $m$  (highest power is  $x^m$ ) and order  $m+1$  ( $m+1$  parameters  $\{c_j\}$ ). If we are given a set of  $m+1$  points

$$y_1 = f(x_1), y_2 = f(x_2), \dots, y_{m+1} = f(x_{m+1})$$

then Lagrange's formula gives a polynomial of degree  $m$  that goes through the  $m+1$  points:

$$\begin{aligned} P_m(x) &= \frac{(x-x_2)(x-x_3) \dots (x-x_{m+1})}{(x_1-x_2)(x_1-x_3) \dots (x_1-x_{m+1})} y_1 \\ &+ \frac{(x-x_1)(x-x_3) \dots (x-x_{m+1})}{(x_2-x_1)(x_2-x_3) \dots (x_2-x_{m+1})} y_2 + \dots \\ &+ \frac{(x-x_1)(x-x_2) \dots (x-x_{m+1})}{(x_{m+1}-x_1)(x_{m+1}-x_2) \dots (x_{m+1}-x_m)} y_{m+1} \end{aligned}$$

Note that each coefficient of  $y_j$  is a polynomial of degree  $m$  that vanishes at the points  $\{x_j\}$  (except for one value of  $j$ ) and takes the value of

1.0 at that point:

$$P_m(x_j) = y_j, \quad j = 1, 2, \dots, m+1$$

If the function  $f(x)$  is known, the error in the approximation is, per Anderson, E., et al., LAPACK Users' Guide, SIAM(1992),

$$|\text{error}(x)| \leq \frac{|x_{m+1} - x_1|^{m+1}}{(m+2)!} \max_{x_1 \leq x \leq x_{m+1}} |f^{(m+2)}(x)|$$

The evaluation of  $P_m(x)$  at a point other than at the defining points can be made with Neville's algorithm [Press et al. (1986)]. Let  $P_1$  be the value at  $x$  of the unique function passing through the point  $(x_1, y_1)$ ; or  $P_1 = y_1$ . Let  $P_{12}$  be the value at  $x$  of the unique polynomial passing through the points  $x_1$  and  $x_2$ . Likewise,  $P_{jk \dots r}$  is the unique polynomial passing through the points  $x_j, x_k, \dots, x_r$ . Then use the table

|       |             |          |           |            |
|-------|-------------|----------|-----------|------------|
| $x_1$ | $y_1 = P_1$ |          |           |            |
| $x_2$ | $y_2 = P_2$ | $P_{12}$ |           |            |
| $x_3$ | $y_3 = P_3$ | $P_{23}$ | $P_{123}$ |            |
| $x_4$ | $y_4 = P_4$ | $P_{34}$ | $P_{234}$ | $P_{1234}$ |

These entries are defined using

$$P_{i(i+1) \dots (i+m)} = \frac{(x - x_{i+m}) P_{i(i+1) \dots (i+m-1)} + (x_i - x) P_{(i+1)(i+2) \dots (i+m)}}{x_i - x_{i+m}}$$

For example, consider  $P_{1234}$ . The terms on the right-hand side involve  $P_{123}$  and  $P_{234}$ . The "parents,"  $P_{123}$  and  $P_{234}$ , already agree at points 2 and 3. Here  $i = 1, m = 3$ ; thus, the parents agree at  $x_{i+1}, \dots, x_{i+m-1}$  already. The formula makes  $P_{i(i+1) \dots (i+m)}$  agree with the function at the additional points  $x_{i+m}$  and  $x_i$ . Thus,  $P_{i(i+1) \dots (i+m)}$  agrees with the function at all the points  $\{x_i, x_{i+1}, \dots, x_{i+m}\}$ .

**Spline Functions** Splines are functions that match given values at the points  $x_1, \dots, x_{NT}$  and have continuous derivatives up to some order at the knots, or the points  $x_2, \dots, x_{NT-1}$ . Cubic splines are most common; see de Boor, C., *A Practical Guide to Splines*, Springer (1978). The function is represented by a cubic polynomial within each interval  $(x_i, x_{i+1})$  and has continuous first and second derivatives at the knots. Two more conditions can be specified arbitrarily. These are usually the second derivatives at the two end points, which are commonly taken as zero; this gives the natural cubic splines.

Take  $y_i = y(x_i)$  at each of the points  $x_i$ , and let  $\Delta x_i = x_{i+1} - x_i$ . Then, in the interval  $(x_i, x_{i+1})$ , the function is represented as a cubic polynomial.

$$C_i(x) = a_{0i} + a_{1i}x + a_{2i}x^2 + a_{3i}x^3$$

The interpolating function takes on specified values at the knots and has continuous first and second derivatives at the knots. Within the  $i$ th interval, the function is

$$\begin{aligned} C_i(x) &= C_i(x_i) + C'_i(x_i)(x - x_i) + C''_i(x_i) \frac{(x - x_i)^2}{2\Delta x_i} \\ &+ [C''_i(x_{i+1}) - C''_i(x_i)] \frac{(x - x_i)^3}{6\Delta x_i} \end{aligned}$$

where  $C_i(x_i) = y_i$ . The second derivative  $C''_i(x_i) = y''_i$  is found by solving the following tridiagonal system of equations:

$$y''_{i-1} \Delta x_{i-1} + y''_i 2(\Delta x_{i-1} + \Delta x_i) + y''_{i+1} \Delta x_i = -6 \left( \frac{y_i - y_{i-1}}{\Delta x_{i-1}} - \frac{y_{i+1} - y_i}{\Delta x_i} \right)$$

Since the continuity conditions apply only for  $i = 2, \dots, NT - 1$ , we have only  $NT - 2$  conditions for the  $NT$  values of  $y''_i$ . Two additional conditions are needed, and these are usually taken as the value of the second derivative at each end of the domain,  $y''_1, y''_{NT}$ . If these values are zero, we get the natural cubic splines; they can also be set to achieve some other purpose, such as making the first derivative match some desired condition at the two ends. With these values taken as zero in the natural cubic spline, we have a  $NT - 2$  system of tridiagonal equations, which is easily solved. Once the second derivatives are

known at each of the knots, the first derivatives are given by

$$y'_i = \frac{y_{i+1} - y_i}{\Delta x_i} - y''_i \frac{\Delta x_i}{3} - y''_{i+1} \frac{\Delta x_i}{6}$$

The function itself is then known within each element.

**NUMERICAL DIFFERENTIATION**

Numerical differentiation should be avoided whenever possible, particularly when data are empirical and subject to appreciable observation errors. Errors in data can affect numerical derivatives quite strongly; i.e., differentiation is a roughening process. When such a calculation must be made, it is usually desirable first to smooth the data to a certain extent.

**Use of Interpolation Formula** If the data are given over equidistant values of the independent variable  $x$ , an interpolation formula such as the Newton formula [Eq. (3-76) or (3-77)] may be used and the resulting formula differentiated analytically. If the independent variable is not at equidistant values, then Lagrange's formulas must be used. By differentiating three-point Lagrange interpolation formulas the following differentiation formulas result for equally spaced tabular points:

**Three-Point Formulas** Let  $x_0, x_1, x_2$  be the three points.

$$\begin{aligned} f'(x_0) &= \frac{1}{2h} [-3f(x_0) + 4f(x_1) - f(x_2)] + \frac{h^2}{3} f'''(\epsilon) \\ f'(x_1) &= \frac{1}{2h} [-f(x_0) + f(x_2)] - \frac{h^2}{6} f'''(\epsilon) \\ f'(x_2) &= \frac{1}{2h} [f(x_0) - 4f(x_1) + 3f(x_2)] + \frac{h^2}{3} f'''(\epsilon) \end{aligned}$$

where the last term is an error term  $\min_j x_j < \epsilon < \max_j x_j$ .

**Smoothing Techniques** These techniques involve the approximation of the tabular data by a least-squares fit of the data by using some known functional form, usually a polynomial (for the concept of least squares see "Statistics"). In place of approximating  $f(x)$  by a single least-squares polynomial of degree  $n$  over the entire range of the tabulation, it is often desirable to replace each tabulated value by the value taken on by a least-squares polynomial of degree  $n$  relevant to a subrange of  $2M + 1$  points centered, when possible, at the point for which the entry is to be modified. Thus each smoothed value replaces a tabulated value. Let  $f_j = f(x_j)$  be the tabular points and  $y_j =$  smoothed values.

**First-Degree Least Squares with Three Points**

$$\begin{aligned} y_0 &= 1/6[5f_0 + 2f_1 - f_2] \\ y_1 &= 1/3[f_0 + f_1 + f_2] \\ y_2 &= 1/6[-f_0 + 2f_1 + 5f_2] \end{aligned}$$

The derivatives at all the points are

$$f'_0 = f'_1 = f'_2 = \frac{1}{2}h [y_2 - y_1]$$

**Second-Degree Least Squares with Five Points** For five evenly spaced points  $x_{-2}, x_{-1}, x_0, x_1,$  and  $x_2$  (separated by distance  $h$ ) and their ordinates  $f_{-2}, f_{-1}, f_0, f_1,$  and  $f_2$ , assume a parabola is fit by least squares. Then the derivative at the center point is

$$f'_0 = 1/10h [-2f_{-2} - f_{-1} + f_1 + 2f_2]$$

The derivatives at the other points are

$$\begin{aligned} f'_{-2} &= 1/70h [-54f_{-2} + 13f_{-1} + 40f_0 + 27f_1 - 26f_2] \\ f'_{-1} &= 1/70h [-34f_{-2} + 3f_{-1} + 20f_0 + 17f_1 - 6f_2] \\ f'_1 &= 1/70h [6f_{-2} - 17f_{-1} - 20f_0 - 3f_1 + 34f_2] \\ f'_2 &= 1/70h [26f_{-2} - 27f_{-1} - 40f_0 - 13f_1 + 54f_2] \end{aligned}$$

**Numerical Derivatives** The results given above can be used to obtain numerical derivatives when solving problems on the computer,

in particular for the Newton-Raphson method and homotopy methods. Suppose one has a program, subroutine, or other function evaluation device that will calculate  $f$  given  $x$ . One can estimate the value of the first derivative at  $x_0$  using

$$\left. \frac{df}{dx} \right|_{x_0} \approx \frac{f[x_0(1 + \epsilon)] - f[x_0]}{\epsilon x_0}$$

(a first-order formula) or

$$\left. \frac{df}{dx} \right|_{x_0} \approx \frac{f[x_0(1 + \epsilon)] - f[x_0(1 - \epsilon)]}{2\epsilon x_0}$$

(a second-order formula). The value of  $\epsilon$  is important; a value of  $10^{-6}$  is typical, but smaller or larger values may be necessary depending on the computer precision and the application. One must also be sure that the value of  $x_0$  is not zero and use a different increment in that case.

**NUMERICAL INTEGRATION (QUADRATURE)**

A multitude of formulas have been developed to accomplish numerical integration, which consists of computing the value of a definite integral from a set of numerical values of the integrand.

**Newton-Cotes Integration Formulas (Equally Spaced Ordinates) for Functions of One Variable** The definite integral  $\int_a^b f(x) dx$  is to be evaluated.

**Trapezoidal Rule** This formula consists of subdividing the interval  $a \leq x \leq b$  into  $n$  subintervals  $a$  to  $a + h, a + h$  to  $a + 2h, \dots$  and replacing the graph of  $f(x)$  by the result of joining the ends of adjacent ordinates by line segments. If  $f_j = f(x_j) = f(a + jh), f_0 = f(a), f_n = f(b)$ , the integration formula is

$$\int_a^b f(x) dx = \frac{h}{2} [f_0 + 2f_1 + 2f_2 + \dots + 2f_{n-1} + f_n] + E_n$$

where  $|E_n| = \frac{nh^3}{12} |f'''(\epsilon)| = \frac{(b-a)^3}{12n^2} |f'''(\epsilon)| \quad a < \epsilon < b$

This procedure is not of high accuracy. However, if  $f'''(x)$  is continuous in  $a < x < b$ , the error goes to zero as  $1/n^2, n \rightarrow \infty$ .

**Parabolic Rule (Simpson's Rule)** This procedure consists of subdividing the interval  $a < x < b$  into  $n/2$  subintervals, each of length  $2h$ , where  $n$  is an even integer. By using the notation as above the integration formula is

$$\int_a^b f(x) dx = \frac{h}{3} [f_0 + 4f_1 + 2f_2 + 4f_3 + \dots + 4f_{n-3} + 2f_{n-2} + 4f_{n-1} + f_n] + E_n$$

where  $|E_n| = \frac{nh^5}{180} |f^{(IV)}(\epsilon)| = \frac{(b-a)^5}{180n^4} |f^{(IV)}(\epsilon)| \quad a < \epsilon < b$

This method approximates  $f(x)$  by a parabola on each subinterval. This rule is generally more accurate than the trapezoidal rule. It is the most widely used integration formula.

**Gaussian Quadrature** Gaussian quadrature provides a highly accurate formula based on irregularly spaced points, but the integral needs to be transformed onto the interval 0 to 1.

$$x = a + (b - a)u, \quad dx = (b - a)du$$

$$\int_a^b f(x) dx = (b - a) \int_0^1 f(u) du$$

$$\int_0^1 f(u) du = \sum_{i=1}^m W_i f(u_i)$$

The quadrature is exact when  $f$  is a polynomial of degree  $2m - 1$  in  $x$ . Because there are  $m$  weights and  $m$  Gauss points, we have  $2m$  parameters that are chosen to exactly represent a polynomial of degree

$2m - 1$ , which has  $2m$  parameters. The Gauss points and weights are given in the table.

**Gaussian Quadrature Points and Weights**

| $m$ | $u_i$         | $W_i$         |
|-----|---------------|---------------|
| 2   | 0.21132 48654 | 0.50000 00000 |
|     | 0.78867 51346 | 0.50000 00000 |
| 3   | 0.11270 16654 | 0.27777 77778 |
|     | 0.50000 00000 | 0.44444 44445 |
|     | 0.88729 83346 | 0.27777 77778 |
| 4   | 0.06943 18442 | 0.17392 74226 |
|     | 0.33000 94783 | 0.32607 25774 |
|     | 0.66999 05218 | 0.32607 25774 |
|     | 0.93056 81558 | 0.17392 74226 |
| 5   | 0.04691 00771 | 0.11846 34425 |
|     | 0.23076 53450 | 0.23931 43353 |
|     | 0.50000 00000 | 0.28444 44444 |
|     | 0.76923 46551 | 0.23931 43353 |
|     | 0.95308 99230 | 0.11846 34425 |

**Example** Calculate the value of the following integral.

$$I = \int_0^1 e^{-x} \sin x \, dx \tag{3-78}$$

Using the Gaussian quadrature formulas gives the following values for various values of  $m$ . Clearly, three internal points, requiring evaluation of the integrand at only three points, gives excellent results.

| $m$ | $I$              |
|-----|------------------|
| 2   | 0.24609643062368 |
| 3   | 0.24583487736505 |
| 4   | 0.24583700444293 |
| 5   | 0.24583700700700 |

**Romberg's Method** Romberg's method uses extrapolation techniques to improve the answer [Press et al. (1986)]. If we let  $I_1$  be the value of the integral obtained using interval size  $h = \Delta x$ , and  $I_2$  be the value of  $I$  obtained when using interval size  $h/2$ , and  $I_0$  the true value of  $I$ , then the error in a method is approximately  $h^m$ , or

$$I_1 \approx I_0 + ch^m$$

$$I_2 \approx I_0 + c\left(\frac{h}{2}\right)^m$$

Replacing the  $\approx$  by an equality (an approximation) and solving for  $c$  and  $I_0$  gives

$$I_0 = \frac{2^m I_2 - I_1}{2^m - 1}$$

This process can also be used to obtain  $I_1, I_2, \dots$ , by halving  $h$  each time, and then calculating new estimates from each pair, calling them  $J_1, J_2, \dots$ ; that is, in the formula above, replace  $I_0$  with  $J_1$ . The formulas are reapplied for each pair of  $J$  to obtain  $K_1, K_2, \dots$ . The process continues until the required tolerance is obtained.

$$\begin{matrix} I_1 & I_2 & I_3 & I_4 \\ J_1 & J_2 & J_3 & \\ & K_1 & K_2 & \\ & & L_1 & \end{matrix}$$

Romberg's method is most useful for a low-order method (small  $m$ ) because significant improvement is then possible.

**Example** Evaluate the same integral (3-78) by using the trapezoid rule and then apply the Romberg method. Use 11, 21, 41, and 81 points with  $m = 2$ . To achieve six-digit accuracy, any result from  $J_2$  through  $L_1$  is suitable, even though the base results ( $I_1$  through  $I_4$ ) are not that accurate.

|                          |                          |                          |                          |
|--------------------------|--------------------------|--------------------------|--------------------------|
| $I_1 = 0.24491148225216$ | $I_2 = 0.24560560017077$ | $I_3 = 0.24577915369183$ | $I_4 = 0.24582254357310$ |
| $J_1 = 0.24583697281030$ | $J_2 = 0.24583700486552$ | $J_3 = 0.24583700686685$ |                          |
|                          | $K_1 = 0.24583701555059$ | $K_2 = 0.24583700753396$ |                          |
|                          |                          | $L_1 = 0.24583700486175$ |                          |

**Computer Methods** These methods are easily programmed in a spreadsheet program such as Microsoft Excel. In MATLAB, the trapezoid rule can be calculated by using the command `trapz(x,y)`, where  $x$  is a vector of  $x$  values  $x_i$  and  $y$  is a vector of values  $y(x_i)$ . Alternatively, use the commands

$$F = @(x) \exp(-x) .* \sin(x)$$

$$Q = \text{quad}(F,0,1)$$

|                          |                          |                          |                          |
|--------------------------|--------------------------|--------------------------|--------------------------|
| $I_1 = 0.24491148225216$ | $I_2 = 0.24560560017077$ | $I_3 = 0.24577915369183$ | $I_4 = 0.24582254357310$ |
|                          | $J_1 = 0.24583697281030$ | $J_2 = 0.24583700486552$ | $J_3 = 0.24583700686685$ |
|                          |                          | $K_1 = 0.24583701555059$ | $K_2 = 0.24583700753396$ |
|                          |                          |                          | $L_1 = 0.24583700486175$ |

**Singularities** When the integrand has singularities, a variety of techniques can be tried. The integral may be divided into one part that can be integrated analytically near the singularity and another part that is integrated numerically. Sometimes a change of argument allows analytical integration. Series expansion might be helpful, too. When the domain is infinite, it is possible to use Gauss-Legendre or Gauss-Hermite quadrature. Also a transformation can be made. For example, let  $u = 1/x$  and then

$$\int_a^b f(x) \, dx = \int_{1/b}^{1/a} \frac{1}{u^2} f\left(\frac{1}{u}\right) \, du \quad ab > 0$$

**Two-Dimensional Formula** Two-dimensional integrals can be calculated by breaking down the integral into one-dimensional integrals.

$$\int_a^b \int_{g_1(x)}^{g_2(x)} f(x, y) \, dx \, dy = \int_a^b G(x) \, dx$$

$$G(x) = \int_{g_1(x)}^{g_2(x)} f(x, y) \, dy$$

Gaussian quadrature can also be used in two dimensions, provided the integration is on a square or can be transformed to one. (Domain transformations might be used to convert the domain to a square.)

$$\int_0^1 \int_0^1 f(x, y) \, dx \, dy = \sum_{i=1}^{m_x} W_{xi} \sum_{j=1}^{m_y} W_{yj} f(x_i, y_j)$$

**NUMERICAL SOLUTION OF ORDINARY DIFFERENTIAL EQUATIONS AS INITIAL VALUE PROBLEMS**

A differential equation for a function that depends on only one variable, often time, is called an ordinary differential equation. The general solution to the differential equation includes many possibilities; the boundary or initial conditions are needed to specify which of those are desired. If all conditions are at one point, then the problem is an initial value problem and can be integrated from that point on. If some of the conditions are available at one point and others at another point, then the ordinary differential equations become two-point boundary value problems, which are treated in the next section. Initial value problems as ordinary differential equations arise in control of lumped parameter models, transient models of stirred tank reactors, and in all models where there are no spatial gradients in the unknowns.

A higher-order differential equation

$$y^{(n)} + F(y^{(n-1)}, y^{(n-2)}, \dots, y', y) = 0$$

with initial conditions

$$G_i(y^{(n-1)}(0), y^{(n-2)}(0), \dots, y(0), y'(0)) = 0, \quad i = 1, \dots, n$$

can be converted into a set of first-order equations using

$$y_i \equiv y^{(i-1)} = \frac{d^{(i-1)}y}{dt^{(i-1)}} = \frac{d}{dt} y^{(i-2)} = \frac{dy_{i-1}}{dt}$$

The higher-order equation can be written as a set of first-order equations.

$$\frac{dy_1}{dt} = y_2$$

$$\begin{aligned} \frac{dy_2}{dt} &= y_3 \\ \frac{dy_3}{dt} &= y_4 \\ &\dots \\ \frac{dy_n}{dt} &= -F(y_{n-1}, y_{n-2}, \dots, y_2, y_1) \end{aligned}$$

The initial conditions would have to be specified for variables  $y_1(0), \dots, y_n(0)$ , or equivalently  $y(0), \dots, y^{(n-1)}(0)$ . The set of equations is then written as

$$\frac{dy}{dt} = \mathbf{f}(\mathbf{y}, t)$$

All the methods in this section are described for a single equation; the methods apply to multiple equations.

Euler's method is first-order.

$$y^{n+1} = y^n + \Delta t f(y^n)$$

and errors are proportional to  $\Delta t$ . The second-order Adams-Bashforth method is

$$y^{n+1} = y^n + \frac{\Delta t}{2} [3f(y^n) - f(y^{n-1})]$$

Errors are proportional to  $\Delta t^2$ , and high-order methods are available. Notice that the higher-order explicit methods require knowing the solution (or the right-hand side) evaluated at times in the past. Since these were calculated to get to the current time, this presents no problem except for starting the problem. Then it may be necessary to use Euler's method with a very small step size for several steps in order to generate starting values at a succession of time points. The error terms, order of the method, function evaluations per step, and stability limitations are listed in Finlayson (2003). The advantage of the high-order Adams-Bashforth method is that it uses only one function evaluation per step yet achieves high-order accuracy. The disadvantage is the necessity of using another method to start.

Runge-Kutta methods are explicit methods that use several function evaluations for each time step. Runge-Kutta methods are traditionally written for  $f(t, y)$ . The first-order Runge-Kutta method is Euler's method. A second-order Runge-Kutta method is

$$y^{n+1} = y^n + \frac{\Delta t}{2} [f^n + f(t^n + \Delta t, y^n + \Delta t f^n)]$$

while the midpoint scheme is also a second-order Runge-Kutta method.

$$y^{n+1} = y^n + \Delta t f\left(t^n + \frac{\Delta t}{2}, y^n + \frac{\Delta t}{2} f^n\right)$$

A popular fourth-order Runge-Kutta method is the Runge-Kutta-Feldberg formulas, which have the property that the method is fourth-order but achieves fifth-order accuracy. The popular integration package RKF45 is based on this method.

$$\begin{aligned} k_1 &= \Delta t f(t^n, y^n) \\ k_2 &= \Delta t f\left(t^n + \frac{\Delta t}{4}, y^n + \frac{k_1}{4}\right) \\ k_3 &= \Delta t f\left(t^n + \frac{3}{8}\Delta t, y^n + \frac{3}{32}k_1 + \frac{9}{32}k_2\right) \\ k_4 &= \Delta t f\left(t^n + \frac{12}{13}\Delta t, y^n + \frac{1932}{2197}k_1 - \frac{7200}{2197}k_2 + \frac{7296}{2197}k_3\right) \\ k_5 &= \Delta t f\left(t^n + \Delta t, y^n + \frac{439}{216}k_1 - 8k_2 + \frac{3680}{513}k_3 - \frac{845}{4104}k_4\right) \\ k_6 &= \Delta t f\left(t^n + \frac{\Delta t}{2}, y^n - \frac{8}{27}k_1 + 2k_2 - \frac{3544}{2565}k_3 + \frac{1859}{4104}k_4 - \frac{11}{40}k_5\right) \end{aligned}$$

$$\begin{aligned} y^{n+1} &= y^n + \frac{25}{216}k_1 + \frac{1408}{2565}k_3 + \frac{2197}{4104}k_4 - \frac{1}{5}k_5 \\ z^{n+1} &= y^n + \frac{16}{135}k_1 + \frac{6656}{12825}k_3 + \frac{28561}{56430}k_4 - \frac{9}{50}k_5 + \frac{2}{55}k_6 \end{aligned}$$

The value of  $y^{n+1} - z^{n+1}$  is an estimate of the error in  $y^{n+1}$  and can be used in step-size control schemes.

Usually one would use a high-order method to achieve high accuracy. The Runge-Kutta-Feldberg method is popular because it is high order and does not require a starting method (as does an Adams-Bashforth method). However, it does require four function evaluations per time step, or four times as many as a fourth-order Adams-Bashforth method. For problems in which the function evaluations are a significant portion of the calculation time, this might be important. Given the speed and availability of desktop computers, the efficiency of the methods is most important only for very large problems that are going to be solved many times. For other problems, the most important criterion for choosing a method is probably the time the user spends setting up the problem.

The stability limits for the explicit methods are based on the largest eigenvalue of the linearized system of equations

$$\frac{dy_i}{dt} = \sum_{j=1}^n A_{ij} y_j, \quad A_{ij} = \left. \frac{\delta f_i}{\delta y_j} \right|_y$$

For linear problems, the eigenvalues do not change, so that the stability and oscillation limits must be satisfied for every eigenvalue of the matrix  $\mathbf{A}$ . When solving nonlinear problems, the equations are linearized about the solution at the local time, and the analysis applies for small changes in time, after which a new analysis about the new solution must be made. Thus, for nonlinear problems, the eigenvalues keep changing, and the largest stable time step changes, too. The stability limits are:

- Euler method,  $\lambda \Delta t \leq 2$
- Runge-Kutta, 2nd order,  $\lambda \Delta t < 2$
- Runge-Kutta-Feldberg,  $\lambda \Delta t < 3.0$

Richardson extrapolation can be used to improve the accuracy of a method. Suppose we step forward one step  $\Delta t$  with a  $p$ th-order method. Then redo the problem, this time stepping forward from the same initial point, but in two steps of length  $\Delta t/2$ , thus ending at the same point. Call the solution of the one-step calculation  $y_1$  and the solution of the two-step calculation  $y_2$ . Then an improved solution at the new time is given by

$$y = \frac{2^p y_2 - y_1}{2^p - 1}$$

This gives a good estimate provided  $\Delta t$  is small enough that the method is truly convergent with order  $p$ . This process can also be repeated in the same way Romberg's method was used for quadrature.

The error term in the various methods can be used to deduce a step size that will give a user-specified accuracy. Most packages today are based on a user-specified tolerance; the step-size is changed during the calculation to achieve that accuracy. The accuracy itself is not guaranteed, but it improves as the tolerance is decreased.

**Implicit Methods** By using different interpolation formulas involving  $y^{n+1}$ , it is possible to derive implicit integration methods. Implicit methods result in a nonlinear equation to be solved for  $y^{n+1}$  so that iterative methods must be used. The backward Euler method is a first-order method.

$$y^{n+1} = y^n + \Delta t f(y^{n+1})$$

Errors are proportional to  $\Delta t$  for small  $\Delta t$ . The trapezoid rule is a second-order method.

$$y^{n+1} = y^n + \frac{\Delta t}{2} [f(y^n) + f(y^{n+1})]$$

Errors are proportional to  $\Delta t^2$  for small  $\Delta t$ . When the trapezoid rule is used with the finite difference method for solving partial differential equations, it is called the Crank-Nicolson method. The implicit methods are stable for any step size but do require the solution of a set of nonlinear equations, which must be solved iteratively. The set of equations can be solved using the successive substitution method

or Newton-Raphson method. See Bogacki, M. B., K. Alejski, and J. Szymanski, *Comp. Chem. Eng.* **13**: 1081–1085 (1989) for an application to dynamic distillation problems.

The best packages for stiff equations (see below) use Gear's backward difference formulas. The formulas of various orders are [Gear, G. W., *Numerical Initial Value Problems in Ordinary Differential Equations*, Prentice-Hall, Englewood Cliffs, N.J. (1971)]

$$(1) y^{n+1} = y^n + \Delta t f(y^{n+1})$$

$$(2) y^{n+1} = \frac{4}{3} y^n - \frac{1}{3} y^{n-1} + \frac{2}{3} \Delta t f(y^{n+1})$$

$$(3) y^{n+1} = \frac{18}{11} y^n - \frac{9}{11} y^{n-1} + \frac{2}{11} y^{n-2} + \frac{6}{11} \Delta t f(y^{n+1})$$

$$(4) y^{n+1} = \frac{48}{25} y^n - \frac{36}{25} y^{n-1} + \frac{16}{25} y^{n-2} - \frac{3}{25} y^{n-3} + \frac{12}{25} \Delta t f(y^{n+1})$$

$$(5) y^{n+1} = \frac{300}{137} y^n - \frac{300}{137} y^{n-1} + \frac{200}{137} y^{n-2} - \frac{75}{137} y^{n-3} + \frac{12}{137} y^{n-4} + \frac{60}{137} \Delta t f(y^{n+1})$$

**Stiffness** The concept of stiffness is described for a system of linear equations.

$$\frac{dy}{dt} = \mathbf{A}y$$

Let  $\lambda_i$  be the eigenvalues of the matrix  $\mathbf{A}$ . The stiffness ratio is defined as

$$SR = \frac{\max_i |\operatorname{Re}(\lambda_i)|}{\min_i |\operatorname{Re}(\lambda_i)|} \quad (3-79)$$

SR = 20 is not stiff, SR =  $10^3$  is stiff, and SR =  $10^6$  is very stiff. If the problem is nonlinear, then the solution is expanded about the current state.

$$\frac{dy_i}{dt} = f_i[y(t^n)] + \sum_{j=1}^n \frac{\partial f_i}{\partial y_j} [y_j - y_j(t^n)]$$

The question of stiffness then depends on the solution at the current time. Consequently nonlinear problems can be stiff during one time period and not stiff during another. While the chemical engineer may not actually calculate the eigenvalues, it is useful to know that they determine the stability and accuracy of the numerical scheme and the step size used.

Problems are stiff when the time constants for different phenomena have very different magnitudes. Consider flow through a packed bed reactor. The time constants for different phenomena are:

1. Time for device flow-through

$$t_{\text{flow}} = \frac{L}{u} = \frac{\phi AL}{Q}$$

where  $Q$  is the volumetric flow rate,  $A$  is the cross sectional area,  $L$  is the length of the packed bed, and  $\phi$  is the void fraction;

2. Time for reaction

$$t_{r \times n} = \frac{1}{k}$$

where  $k$  is a rate constant ( $\text{time}^{-1}$ );

3. Time for diffusion inside the catalyst

$$t_{\text{internal diffusion}} = \frac{\epsilon R^2}{D_e}$$

where  $\epsilon$  is the porosity of the catalyst,  $R$  is the catalyst radius, and  $D_e$  is the effective diffusion coefficient inside the catalyst;

4. Time for heat transfer is

$$t_{\text{internal heat transfer}} = \frac{R^2}{\alpha} = \frac{\rho_s C_s R^2}{k_c}$$

where  $\rho_s$  is the catalyst density,  $C_s$  is the catalyst heat capacity per unit mass,  $k_c$  is the effective thermal conductivity of the catalyst, and

$\alpha$  is the thermal diffusivity. For example, in the model of a catalytic converter for an automobile [Ferguson, N. B., and B. A. Finlayson, *AIChE J.* **20**:539–550 (1974)], the time constants for internal diffusion was 0.3 seconds; internal heat transfer, 21 seconds; and device flow-through, 0.003 seconds. The device flow-through is so fast that it might as well be instantaneous. The stiffness is approximately 7000. Implicit methods must be used to integrate the equations. Alternatively, a quasistate model can be developed [Ramirez, W. F., *Computational Methods for Process Simulations*, 2d ed., Butterworth-Heinemann, Boston (1997)].

**Differential-Algebraic Systems** Sometimes models involve ordinary differential equations subject to some algebraic constraints. For example, the equations governing one equilibrium stage (as in a distillation column) are

$$M \frac{dx^n}{dt} = V^{n+1} y^{n+1} - L^n x^n - V^n y^n + L^{n-1} x^{n-1}$$

$$x^{n-1} - x^n = E^n (x^{n-1} - x^{*n})$$

$$\sum_{i=1}^N x_i = 1$$

where  $x$  and  $y$  are the mole fraction in the liquid and vapor, respectively;  $L$  and  $V$  are liquid and vapor flow rates, respectively;  $M$  is the holdup; and the superscript is the stage number. The efficiency is  $E$ , and the concentration in equilibrium with the vapor is  $x^*$ . The first equation is an ordinary differential equation for the mass of one component on the stage, while the third equation represents a constraint that the mass fractions add to one. This is a differential-algebraic system of equations.

Differential-algebraic equations can be written in the general notation

$$F\left(t, y, \frac{dy}{dt}\right) = 0$$

To solve the general problem using the backward Euler method, replace the nonlinear differential equation with the nonlinear algebraic equation for one step.

$$F\left(t, y^{n+1}, \frac{y^{n+1} - y^n}{\Delta t}\right) = 0$$

This equation must be solved for  $y^{n+1}$ . The Newton-Raphson method can be used, and if convergence is not achieved within a few iterations, the time step can be reduced and the step repeated. In actuality, the higher-order backward-difference Gear methods are used in DASSL [Ascher, U. M., and L. R. Petzold, *Computer Methods for Ordinary Differential Equations and Differential-Algebraic Equations*, SIAM, Philadelphia (1998); and Brennan, K. E., S. L. Campbell, and L. R. Petzold, *Numerical Solution of Initial-Value Problems in Differential-Algebraic Equations*, North Holland: Elsevier (1989)].

Differential-algebraic systems are more complicated than differential systems because the solution may not always be defined. Pontelides et al. [*Comp. Chem. Eng.* **12**: 449–454 (1988)] introduced the term *index* to identify the possible problems. The index is defined as the minimum number of times the equations need to be differentiated with respect to time to convert the system to a set of ordinary differential equations. These higher derivatives may not exist, and the process places limits on which variables can be given initial values. Sometimes the initial values must be constrained by the algebraic equations. For a differential-algebraic system modeling a distillation tower, Pontelides et al. show that the index depends on the specification of pressure for the column. Byrne and Ponzi [*Comp. Chem. Eng.* **12**: 377–382 (1988)]; also Chan, T. F. C., and H. B. Keller, *SIAM J. Sci. Stat. Comput.* **3**: 173–194 (1982)] also list several chemical engineering examples of differential-algebraic systems and solve one involving two-phase flow.

**Computer Software** Efficient computer packages are available for solving ordinary differential equations as initial value problems. The packages are widely available and good enough that most chemical engineers use them and do not write their own. Here we discuss three of them: RKF45, LSODE, and EPISODE. In each of the packages, the user specifies the differential equation to be solved and a

desired error criterion. The package then integrates in time and adjusts the step size to achieve the error criterion within the limitations imposed by stability.

A popular explicit, Runge-Kutta package is RKF45. Notice there that an estimate of the truncation error at each step is available. Then the step size can be reduced until this estimate is below the user-specified tolerance. The method is thus automatic, and the user is assured of the results. Note, however, that the tolerance is set on the local truncation error, namely from one step to another, whereas the user is usually interested in the global truncation error, or the error after several steps. The global error is generally made smaller by making the tolerance smaller, but the absolute accuracy is not the same as the tolerance. If the problem is stiff, then very small step sizes are used; the computation becomes very lengthy. The RKF45 code discovers this and returns control to the user with a message indicating the problem is too hard to solve with RKF45.

A popular implicit package is LSODE, a version of Gear's method (Gear, *ibid.*) written by Alan Hindmarsh at Lawrence Livermore Laboratory. In this package, the user specifies the differential equation to be solved and the tolerance desired. Now the method is implicit and therefore stable for any step size. The accuracy may not be acceptable, however, and sets of nonlinear equations must be solved. Thus, in practice the step size is limited but not nearly so much as in the Runge-Kutta methods. In these packages, both the step size and order of the method are adjusted by the package. Suppose we are calculating with a  $k$ th order method. The truncation error is determined by the  $(k+1)$ th order derivative. This is estimated using difference formulas and the values of the right-hand sides at previous times. An estimate is also made for the  $k$ th and  $(k+2)$ th derivative. Then it is possible to estimate the error in a  $(k-1)$ th order method, a  $k$ th order method, and a  $(k+1)$ th order method. Furthermore, the step size needed to satisfy the tolerance with each of these methods can be determined. Then we can choose the method and step size for the next step that achieves the biggest step, with appropriate adjustments due to the different work required for each order. The package generally starts with a very small step size and a first-order method, the backward Euler method. Then it integrates along, adjusting the order up (and later down) depending on the error estimates. The user is thus assured that the local truncation error meets the tolerance. There is a further difficulty, since the set of nonlinear equations must be solved. Usually a good guess of the solution is available, since the solution is evolving in time and past history can be extrapolated. Thus, the Newton-Raphson method will usually converge. The package protects itself, though, by only doing a few iterations. If convergence is not reached within this many iterations, then the step size is reduced and the calculation is redone for that time step. The convergence theorem for the Newton-Raphson method (p. 3-50) indicates that the method will converge if the step size is small enough. Thus the method is guaranteed to work. Further economies are possible. The Jacobian needed in the Newton-Raphson method can be fixed over several time steps. Then, if the iteration does not converge, the Jacobian can be reevaluated at the current time-step. If the iteration still does not converge, then the step-size is reduced and a new Jacobian is evaluated. Also the successive substitution method can be used, which is even faster, except that it may not converge. However, it, too, will converge if the time step is small enough.

The Runge-Kutta methods give extremely good accuracy, especially when the step size is kept small for stability reasons. If the problem is stiff, though, backward difference implicit methods must be used. Many chemical reactor problems are stiff, necessitating the use of implicit methods. In the MATLAB suite of ODE solvers, the ode45 uses a revision of the RKF45 program, while the ode15s program uses an improved backward difference method. Shampine and Reichelt [SIAM J. Sci. Comp. 18:1-22 (1997)] give details of the programs in MATLAB. Fortunately, many packages are available. On the NIST web page <http://gams.nist.gov/>, choose "problem decision tree" and then "differential and integral equations" to find packages that can be downloaded. On the Netlib web site <http://www.netlib.org/>, choose "ode" to find packages that can be downloaded. Using Microsoft Excel to solve ordinary differential equations is cumbersome, except for the simplest problems.

**Stability, Bifurcations, Limit Cycles** Some aspects of this subject involve the solution of nonlinear equations; other aspects involve

the integration of ordinary differential equations; applications include chaos and fractals as well as unusual operation of some chemical engineering equipment. Kubicek, M., and M. Marek, *Computational Methods in Bifurcation Theory and Dissipative Structures*, Springer-Verlag, Berlin (1983), give an excellent introduction to the subject and the details needed to apply the methods. Chan, T. F. C., and H. B. Keller, *SIAM J. Sci. Stat. Comput.* 3:173-194 (1982), give more details of the algorithms. A concise survey with some chemical engineering examples is given in Doherty, M. F., and J. M. Ottino, *Chem. Eng. Sci.* 43:139-183 (1988). Bifurcation results are closely connected with stability of the steady states, which is essentially a transient phenomenon.

**Sensitivity Analysis** When solving differential equations, it is frequently necessary to know the solution as well as the sensitivity of the solution to the value of a parameter. Such information is useful when doing parameter estimation (to find the best set of parameters for a model) and for deciding if a parameter needs to be measured accurately. See Finlayson, et al. (2006).

**Molecular Dynamics** Special integration methods have been developed for molecular dynamics calculations due to the structure of the equations. A very large number of equations are to be integrated, with the following form based on molecular interactions between molecules.

$$m_i \frac{d^2 \mathbf{r}_i}{dt^2} = \mathbf{F}_i(\{\mathbf{r}\}) \quad \mathbf{F}_i(\{\mathbf{r}\}) = -\nabla V$$

The symbol  $m_i$  is the mass of the  $i$ th particle,  $\mathbf{r}_i$  is the position of the  $i$ th particle,  $\mathbf{F}_i$  is the force acting on the  $i$ th particle, and  $V$  is the potential energy that depends upon the location of all the particles (but not their velocities). Since the major part of the calculation lies in the evaluation of the forces, or potentials, a method must be used that minimizes the number of times the forces are calculated to move from one time to another time. Rewrite this equation in the form of an acceleration as

$$\frac{d^2 \mathbf{r}_i}{dt^2} = \frac{1}{m_i} \mathbf{F}_i(\{\mathbf{r}\}) \equiv \mathbf{a}_i$$

In the Verlet method, this equation is written by using central finite differences (see "Interpolation and Finite Differences"). Note that the accelerations do not depend upon the velocities.

$$\mathbf{r}_i(t + \Delta t) = 2\mathbf{r}_i(t) - \mathbf{r}_i(t - \Delta t) + \mathbf{a}_i(t)\Delta t^2$$

The calculations are straightforward, and no explicit velocity is needed. The storage requirement is modest, and the precision is modest (it is a second-order method). Note that one must start the calculation with values of  $\{\mathbf{r}\}$  at times  $t$  and  $t - \Delta t$ .

In the Verlet velocity method, an equation is written for the velocity, too.

$$\frac{d\mathbf{v}_i}{dt} = \mathbf{a}_i$$

The trapezoid rule [see "Numerical Integration (Quadrature)"] is applied to obtain

$$\mathbf{v}_i(t + \Delta t) = \mathbf{v}_i(t) + \frac{1}{2} [\mathbf{a}_i(t) + \mathbf{a}_i(t + \Delta t)] \Delta t$$

The position of the particles is expanded in a Taylor series.

$$\mathbf{r}_i(t + \Delta t) = \mathbf{r}_i(t) + \mathbf{v}_i \Delta t + \frac{1}{2} \mathbf{a}_i(t) \Delta t^2$$

Beginning with values of  $\{\mathbf{r}\}$  and  $\{\mathbf{v}\}$  at time 0, one calculates the new positions and then the new velocities. This method is second-order in  $\Delta t$ , too. For additional details, see Allen, M. P., and D. J. Tildesley, *Computer Simulation of Liquids*, Clarendon Press, Oxford (1989); Frenkel, D., and B. Smit, *Understanding Molecular Simulation*, Academic Press (2002); Haile, J. M., *Molecular Dynamics Simulation*, Wiley (1992); Leach, A. R., *Molecular Modelling: Principles and Applications*, Prentice-Hall (2001); Schlick, T., *Molecular Modeling and Simulations*, Springer, New York (2002).

## ORDINARY DIFFERENTIAL EQUATIONS-BOUNDARY VALUE PROBLEMS

Diffusion problems in one dimension lead to boundary value problems. The boundary conditions are applied at two different spatial

locations: at one side the concentration may be fixed and at the other side the flux may be fixed. Because the conditions are specified at two different locations, the problems are not initial value in character. It is not possible to begin at one position and integrate directly because at least one of the conditions is specified somewhere else and there are not enough conditions to begin the calculation. Thus, methods have been developed especially for boundary value problems.

Boundary value methods provide a description of the solution either by providing values at specific locations or by an expansion in a series of functions. Thus, the key issues are the method of representing the solution, the number of points or terms in the series, and how the approximation converges to the exact answer, i.e., how the error changes with the number of points or number of terms in the series. These issues are discussed for each of the methods: finite difference, orthogonal collocation, and Galerkin finite element methods.

**Finite Difference Method** To apply the finite difference method, we first spread grid points through the domain. Figure 3-48 shows a uniform mesh of  $n$  points (nonuniform meshes are possible, too). The unknown, here  $c(x)$ , at a grid point  $x_i$  is assigned the symbol  $c_i = c(x_i)$ . The finite difference method can be derived easily by using a Taylor expansion of the solution about this point. Expressions for the derivatives are:

$$\frac{dc}{dx}\bigg|_i = \frac{c_{i+1} - c_i}{\Delta x} - \frac{d^2c}{dx^2}\bigg|_i \frac{\Delta x}{2} + \dots, \quad \frac{dc}{dx}\bigg|_i = \frac{c_i - c_{i-1}}{\Delta x} + \frac{d^2c}{dx^2}\bigg|_i \frac{\Delta x}{2} + \dots$$

$$\frac{d^2c}{dx^2}\bigg|_i = \frac{c_{i+1} - 2c_i + c_{i-1}}{2\Delta x} - \frac{d^3c}{dx^3}\bigg|_i \frac{\Delta x^2}{3!} + \dots$$

The truncation error in the first two expressions is proportional to  $\Delta x$ , and the methods are said to be first-order. The truncation error in the third expression is proportional to  $\Delta x^2$ , and the method is said to be second-order. Usually the last equation is used to insure the best accuracy. The finite difference representation of the second derivative is:

$$\frac{d^2c}{dx^2}\bigg|_i = \frac{c_{i+1} - 2c_i + c_{i-1}}{\Delta x^2} - \frac{d^4c}{dx^4}\bigg|_i \frac{2\Delta x^2}{4!} + \dots$$

The truncation error is proportional to  $\Delta x^2$ . To solve a differential equation, it is evaluated at a point  $i$  and then these expressions are inserted for the derivatives.

**Example** Consider the equation for convection, diffusion, and reaction in a tubular reactor.

$$\frac{1}{Pe} \frac{d^2c}{dx^2} - \frac{dc}{dx} = Da R(c)$$

The finite difference representation is

$$\frac{1}{Pe} \frac{c_{i+1} - 2c_i + c_{i-1}}{\Delta x^2} - \frac{c_{i+1} - c_{i-1}}{2\Delta x} = Da R(c_i)$$

This equation is written for  $i = 2$  to  $n - 1$ , or the internal points. The equations would then be coupled but would also involve the values of  $c_1$  and  $c_n$ , as well. These are determined from the boundary conditions.

If the boundary condition involves a derivative, it is important that the derivatives be evaluated using points that exist. Three possibilities exist:

$$\frac{dc}{dx}\bigg|_1 = \frac{c_2 - c_1}{\Delta x}$$

$$\frac{dc}{dx}\bigg|_1 = \frac{-3c_1 + 4c_2 - c_3}{2\Delta x}$$

The third alternative is to add a false point, outside the domain, as  $c_0 = c(x = -\Delta x)$ .

$$\frac{dc}{dx}\bigg|_1 = \frac{c_2 - c_0}{2\Delta x}$$

Since this equation introduces a new variable,  $c_0$ , another equation is needed and is obtained by writing the finite difference equation for  $i = 1$ , too.

FIG. 3-48 Finite difference mesh;  $\Delta x$  uniform.

The sets of equations can be solved using the Newton-Raphson method. The first form of the derivative gives a tridiagonal system of equations, and the standard routines for solving tridiagonal equations suffice. For the other two options, some manipulation is necessary to put them into a tridiagonal form.

Frequently, the transport coefficients, such as diffusion coefficient or thermal conductivity, depend on the dependent variable, concentration, or temperature, respectively. Then the differential equation might look like

$$\frac{d}{dx} \left( D(c) \frac{dc}{dx} \right) = 0$$

This could be written as two equations.

$$-\frac{dJ}{dx} = 0 \quad J = -D(c) \frac{dc}{dx}$$

Because the coefficient depends on  $c$ , the equations are more complicated. A finite difference method can be written in terms of the fluxes at the midpoints,  $i + 1/2$ .

$$-\frac{J_{i+1/2} - J_{i-1/2}}{\Delta x} = 0 \quad J_{i+1/2} = -D(c_{i+1/2}) \frac{c_{i+1} - c_i}{\Delta x}$$

These are combined to give the complete equation.

$$\frac{D(c_{i+1/2})(c_{i+1} - c_i) - D(c_{i-1/2})(c_i - c_{i-1})}{\Delta x^2} = 0$$

This represents a set of nonlinear algebraic equations that can be solved with the Newton-Raphson method. However, in this case, a viable iterative strategy is to evaluate the transport coefficients at the last value and then solve

$$\frac{D(c_{i+1/2}^k)(c_{i+1}^{k+1} - c_i^{k+1}) - D(c_{i-1/2}^k)(c_i^{k+1} - c_{i-1}^{k+1})}{\Delta x^2} = 0$$

The advantage of this approach is that it is easier to program than a full Newton-Raphson method. If the transport coefficients do not vary radically, then the method converges. If the method does not converge, then it may be necessary to use the full Newton-Raphson method.

There are two common ways to evaluate the transport coefficient at the midpoint: Use the average value of the solution on each side to evaluate the diffusivity, or use the average value of the diffusivity on each side. Both methods have truncation error  $\Delta x^2$  (Finlayson, 2003). The spacing of the grid points need not be uniform; see Finlayson (2003) and Finlayson et al. (2006) for the formulas in that case.

**Example** A reaction diffusion problem is solved with the finite difference method.

$$\frac{d^2c}{dx^2} = \phi^2 c, \quad \frac{dc}{dx}(0) = 0, \quad c(1) = 1$$

The solution is derived for  $\phi = 2$ . It is solved several times, first with two intervals and three points (at  $x = 0, 0.5, 1$ ), then with four intervals, then with eight intervals. The reason is that when an exact solution is not known, one must use several  $\Delta x$  and see that the solution converges as  $\Delta x$  approaches zero. With two intervals, the equations are as follows. The points are  $x_1 = 0$ ,  $x_2 = 0.5$ , and  $x_3 = 1.0$ ; and the solution at those points are  $c_1$ ,  $c_2$ , and  $c_3$ , respectively. A false boundary is used at  $x_0 = -0.5$ .

$$\frac{c_0 - c_2}{2\Delta x} = 0, \quad \frac{c_0 - 2c_1 + c_2}{\Delta x^2} - \phi^2 c_1 = 0, \quad \frac{c_1 - 2c_2 + c_3}{\Delta x^2} - \phi^2 c_2 = 0, \quad c_3 = 1$$

The solution is  $c_1 = 0.2857$ ,  $c_2 = 0.4286$ , and  $c_3 = 1.0$ . The problem is solved again with four and then eight intervals. The value of concentration at  $x = 0$  takes the following values for different  $\Delta x$ . These values are extrapolated using the Richardson extrapolation technique to give  $c(0) = 0.265718$ . Using this value as the best estimate of the exact solution, the errors in the solution are tabulated versus  $\Delta x$ . Clearly the errors go as  $\Delta x^2$  (decreasing by a factor of 4 when  $\Delta x$  decreases by a factor of 2), thus validating the solution. The exact solution is 0.265802.

| $n - 1$ | $\Delta x$ | $c(0)$   |
|---------|------------|----------|
| 2       | 0.5        | 0.285714 |
| 4       | 0.25       | 0.271043 |
| 8       | 0.125      | 0.267131 |

| $n - 1$ | $\Delta x$ | Error in $c(0)$ |
|---------|------------|-----------------|
| 2       | 0.5        | 0.02000         |
| 4       | 0.25       | 0.00532         |
| 8       | 0.125      | 0.00141         |

**Finite Difference Methods Solved with Spreadsheets** A convenient way to solve the finite difference equations for simple problems is to use a computer spreadsheet. The equations for the problem solved in the example can be cast into the following form

$$c_i = \frac{2c_2}{2 + \phi^2 \Delta x^2}$$

FIG. 3-49 Finite difference method using spreadsheets.

$$c_i = \frac{c_{i+1} + c_{i-1}}{2 + \phi^2 \Delta x^2}$$

$$c_{n+1} = 1$$

Let us solve the problem using 6 nodes, or 5 intervals. Then the connection between the cell in the spreadsheet and the nodal value is shown in Fig. 3-49. The following equations are placed into the various cells.

A1: = 2\*B1/(2.+(phi\*dx)\*\*2)  
 B1: = (A1 + C1)/(2.+(phi\*dx)\*\*2)  
 F1: = 1.

The equation in cell B1 is copied into cells C1 though E1. Then turn on the iteration scheme in the spreadsheet and watch the solution converge. Whether or not convergence is achieved can depend on how you write the equations, so some experimentation may be necessary. Theorems for convergence of the successive substitution method are useful in this regard.

**Orthogonal Collocation** The orthogonal collocation method has found widespread application in chemical engineering, particularly for chemical reaction engineering. In the collocation method, the dependent variable is expanded in a series of orthogonal polynomials. See “Interpolation and Finite Differences: Lagrange Interpolation Formulas.”

$$c(x) = \sum_{m=0}^N a_m P_m(x)$$

The differential equation is evaluated at certain collocation points. The collocation points are the roots to an orthogonal polynomial, as first used by Lanczos [Lanczos, C., *J. Math. Phys.* **17**:123–199 (1938); and Lanczos, C., *Applied Analysis*, Prentice-Hall (1956)]. A major improvement was proposed by Villadsen and Stewart [Villadsen, J. V., and W. E. Stewart, *Chem. Eng. Sci.* **22**:1483–1501 (1967)], who proposed that the entire solution process be done in terms of the solution at the collocation points rather than the coefficients in the expansion. This method is especially useful for reaction-diffusion problems that frequently arise when modeling chemical reactors. It is highly efficient when the solution is smooth, but the finite difference method is preferred when the solution changes steeply in some region of space. The error decreases very rapidly as  $N$  is increased since it is proportional to  $[1/(1 - N)]^{N-1}$ . See Finlayson (2003) and Villadsen, J. V., and M. Michelsen, *Solution of Differential Equation Models by Polynomial Approximations*, Prentice-Hall (1978).

**Galerkin Finite Element Method** In the finite element method, the domain is divided into elements and an expansion is made for the solution on each finite element. In the Galerkin finite element method an additional idea is introduced: the Galerkin method is used to solve the equation. The Galerkin method is explained before the finite element basis set is introduced, using the equations for reaction and diffusion in a porous catalyst pellet.

$$\frac{d^2c}{dx^2} = \phi^2 R(c)$$

$$\frac{dc}{dx}(0) = 0, \quad c(1) = 1$$

The unknown solution is expanded in a series of known functions  $\{b_j(x)\}$  with unknown coefficients  $\{a_j\}$ .

$$c(x) = \sum_{i=1}^{NT} a_i b_i(x)$$

The trial solution is substituted into the differential equation to obtain

the residual.

$$\text{Residual} = \sum_{i=1}^{NT} a_i \frac{d^2 b_i}{dx^2} - \phi^2 R \left[ \sum_{i=1}^{NT} a_i b_i(x) \right]$$

The residual is then made orthogonal to the set of basis functions.

$$\int_0^1 b_j(x) \left\{ \sum_{i=1}^{NT} a_i \frac{d^2 b_i}{dx^2} - \phi^2 R \left[ \sum_{i=1}^{NT} a_i b_i(x) \right] \right\} dx = 0 \quad j = 1, \dots, NT$$

This is the process that makes the method a Galerkin method. The basis for the orthogonality condition is that a function that is made orthogonal to each member of a complete set is then zero. The residual is being made orthogonal, and if the basis functions are complete and you use infinitely many of them, then the residual is zero. Once the residual is zero, the problem is solved.

This equation is integrated by parts to give the following equation

$$-\sum_{i=1}^{NT} \int_0^1 \frac{db_i}{dx} \frac{db_i}{dx} dx a_i = \phi^2 \int_0^1 b_j(x) R \left[ \sum_{i=1}^{NT} a_i b_i(x) \right] dx \quad j = 1, \dots, NT - 1 \quad (3-80)$$

This equation defines the Galerkin method and a solution that satisfies this equation (for all  $j = 1, \dots, \infty$ ) is called a weak solution. For an approximate solution, the equation is written once for each member of the trial function,  $j = 1, \dots, NT - 1$ , and the boundary condition is applied.

$$\sum_{i=1}^{NT} a_i b_i(1) = c_B$$

The Galerkin finite element method results when the Galerkin method is combined with a finite element trial function. The domain is divided into elements separated by nodes, as in the finite difference method. The solution is approximated by a linear (or sometimes quadratic) function of position within the element. These approximations are substituted into Eq. (3-80) to provide the Galerkin finite element equations. For example, with the grid shown in Fig. 3-48, a linear interpolation would be used between points  $x_i$  and  $x_{i+1}$ .

$$c(x) = c_i(1 - u) + c_{i+1}u \quad u = \frac{x - x_i}{x_{i+1} - x_i}$$

A finite element method based on these functions would have an error proportional to  $\Delta x^2$ . The finite element representations for the first derivative and second derivative are the same as in the finite difference method, but this is not true for other functions or derivatives. With quadratic finite elements, take the region from  $x_{i-1}$  and  $x_{i+1}$  as one element. Then the interpolation would be

$$c(x) = c_{i-1}N_1(u) + c_i N_2(u) + c_{i+1}N_3(u)$$

$$N_1(u) = 2(u-1)\left(u - \frac{1}{2}\right) \quad N_2(u) = 4u(1-u)$$

$$N_3(u) = 2u\left(u - \frac{1}{2}\right)$$

A finite element method based on these functions would have an error proportional to  $\Delta x^3$ . Thus, it would converge faster than one based on linear interpolation. A variety of other finite element functions can be used as well, including B splines (see “Interpolation and Finite Differences: Spline Functions”).

**Adaptive Meshes** In many two-point boundary value problems, the difficulty in the problem is the formation of a boundary layer region, or a region in which the solution changes very dramatically. In such cases, it is prudent to use small mesh spacing there, either with the finite difference method or the finite element method. If the region is known *a priori*, small mesh spacings can be assumed at the boundary layer. If the region is not known, though, other techniques must be used. These techniques are known as adaptive mesh techniques. The mesh size is made small where some property of the solution is large. For example, if the truncation error of the method is  $n$ th order, then the  $n$ th-order derivative of the solution is evaluated and a small mesh is used where it is large. Alternatively, the residual (the differential equation with the numerical

solution substituted into it) can be used as a criterion. It is also possible to define the error that is expected from a method one order higher and one order lower. Then a decision about whether to increase or decrease the order of the method can be made, taking into account the relative work of the different orders. This provides a method of adjusting both the mesh spacing ( $\Delta x$ , or sometimes called  $h$ ) and the degree of polynomial ( $p$ ). Such methods are called  $h$ - $p$  methods. Many finite element programs have the capability to do this mesh refinement automatically.

**Singular Problems and Infinite Domains** If the solution being sought has a singularity, it may be difficult to find a good numerical solution. Sometimes even the location of the singularity may not be known. One method of solving such problems is to refine the mesh near the singularity, relying on the better approximation due to a smaller  $\Delta x$ . Another approach is to incorporate the singular trial function into the approximation. Thus, if the solution approaches  $f(x)$  as  $x$  goes to zero and  $f(x)$  becomes infinite, one may define a new variable  $u(x) = y(x) - f(x)$  and derive an equation for  $u$ . The differential equation is more complicated, but the solution is better near the singularity. Press et al. (1986).

Sometimes the domain is semi-infinite, as in boundary layer flow. The domain can be transformed from the  $x$  domain  $(0 - \infty)$  to the  $\eta$  domain  $(1 - 0)$  using the transformation  $\eta = \exp(-x)$ . Another approach is to use a variable mesh, perhaps with the same transformation. For example, use  $\eta = \exp(-\beta x)$  and a constant mesh size in  $\eta$ ; the value of  $\beta$  is found experimentally. Still another approach is to solve on a finite mesh in which the last point is far enough away that its location does not influence the solution. A location that is far enough away must be found by trial and error.

Packages to solve boundary value problems are available on the Internet. On the NIST web page <http://gams.nist.gov/>, choose "problem decision tree" and then "differential and integral equations" and then "ordinary differential equations" and "multipoint boundary value problems." On the Netlib web site <http://www.netlib.org/>, search on "boundary value problem." Any spreadsheet that has an iteration capability can be used with the finite difference method. Some packages for partial differential equations also have a capability for solving one-dimensional boundary value problems [e.g. Comsol Multiphysics (formerly FEMLAB)].

**NUMERICAL SOLUTION OF INTEGRAL EQUATIONS**

In this subsection is considered a method of solving numerically the Fredholm integral equation of the second kind:

$$u(x) = f(x) + \lambda \int_a^b k(x, t)u(t) dt \quad \text{for } u(x) \quad (3-81)$$

The method discussed arises because a definite integral can be closely approximated by any of several numerical integration formulas (each of which arises by approximating the function by some polynomial over an interval). Thus the definite integral in Eq. (3-81) can be replaced by an integration formula, and Eq. (3-81) may be written

$$u(x) = f(x) + \lambda(b - a) \left[ \sum_{i=1}^n c_i k(x, t_i) u(t_i) \right] \quad (3-82)$$

where  $t_1, \dots, t_n$  are points of subdivision of the  $t$  axis,  $a \leq t \leq b$ , and the  $c$ 's are coefficients whose values depend upon the type of numerical integration formula used. Now Eq. (3-82) must hold for all values of  $x$ ,  $a \leq x \leq b$ ; so it must hold for  $x = t_1, x = t_2, \dots, x = t_n$ . Substituting for  $x$  successively  $t_1, t_2, \dots, t_n$  and setting  $u(t_i) = u_i, f(t_i) = f_i$ , we get  $n$  linear algebraic equations for the  $n$  unknowns  $u_1, \dots, u_n$ . That is,

$$u_i = f_i + \lambda(b - a) [c_1 k(t_i, t_1) u_1 + c_2 k(t_i, t_2) u_2 + \dots + c_n k(t_i, t_n) u_n] \quad i = 1, 2, \dots, n$$

These  $u_i$  may be solved for by the methods under "Numerical Solution of Linear Equations and Associated Problems" and substituted into Eq. (3-82) to yield an approximate solution for Eq. (3-81).

Because of the work involved in solving large systems of simultaneous linear equations it is desirable that only a small number of  $u$ 's be computed. Thus the gaussian integration formulas are useful because of the economy they offer.

Solutions for Volterra equations are done in a similar fashion, except that the solution can proceed point by point, or in small groups of points depending on the quadrature scheme. See Linz, P., *Analytical and Numerical Methods for Volterra Equations*, SIAM, Philadelphia (1985). There are methods that are analogous to the usual methods for

integrating differential equations (Runge-Kutta, predictor-corrector, Adams methods, etc.). Explicit methods are fast and efficient until the time step is very small to meet the stability requirements. Then implicit methods are used, even though sets of simultaneous algebraic equations must be solved. The major part of the calculation is the evaluation of integrals, however, so that the added time to solve the algebraic equations is not excessive. Thus, implicit methods tend to be preferred. Volterra equations of the first kind are not well posed, and small errors in the solution can have disastrous consequences. The boundary element method uses Green's functions and integral equations to solve differential equations. See Brebbia, C. A., and J. Dominguez, *Boundary Elements—An Introductory Course*, 2d ed., Computational Mechanics Publications, Southampton (1992); and Mackerle, J., and C. A. Brebbia (eds.), *Boundary Element Reference Book*, Springer-Verlag (1988).

**MONTE CARLO SIMULATIONS**

Some physical problems, such as those involving interaction of molecules, are usually formulated as integral equations. Monte Carlo methods are especially well-suited to their solution. This section cannot give a comprehensive treatment of such methods, but their use in calculating the value of an integral will be illustrated. Suppose we wish to calculate the integral

$$G = \int_{\Omega_0} g(x)f(x) dx$$

where the distribution function  $f(x)$  satisfies:

$$f(x) \geq 0, \quad \int_{\Omega_0} f(x) dx = 1$$

The distribution function  $f(x)$  can be taken as constant; for example,  $1/\Omega_0$ . We choose variables  $x_1, x_2, \dots, x_N$  randomly from  $f(x)$  and form the arithmetic mean

$$G_N = \frac{1}{N} \sum_i g(x_i)$$

The quantity  $G_N$  is an estimation of  $G$ , and the fundamental theorem of Monte Carlo guarantees that the expected value of  $G_N$  is  $G$ , if  $G$  exists [Kalos, M. H., and P. A. Whitlock, *Monte Carlo Methods*, vol. 1, Wiley, New York (1986)]. The error in the calculation is given by

$$\epsilon = \frac{\sigma_1}{N^{1/2}}$$

where  $\sigma_1^2$  is calculated from

$$\sigma_1^2 = \int_{\Omega_0} g^2(x)f(x) dx - G^2$$

Thus the number of terms needed to achieve a specified accuracy  $\epsilon$  can be calculated once an estimate of  $\sigma_1^2$  is known.

$$N = \frac{\sigma_1^2}{\epsilon^2}$$

Various methods, such as influence sampling, can be used to reduce the number of calculations needed. See also Lapeyre, B., *Introduction to Monte-Carlo Methods for Transport and Diffusion Equations*, Oxford University Press (2003), and Liu, J. S., *Monte Carlo Strategies in Scientific Computing*, Springer (2001). Some computer programs are available that perform simple Monte Carlo calculations using Microsoft Excel.

**NUMERICAL SOLUTION OF PARTIAL DIFFERENTIAL EQUATIONS**

The numerical methods for partial differential equations can be classified according to the type of equation (see "Partial Differential Equations"); parabolic, elliptic, and hyperbolic. This section uses the finite difference method to illustrate the ideas, and these results can be programmed for simple problems. For more complicated problems, though, it is common to rely on computer packages. Thus, some discussion is given to the issues that arise when using computer packages.

**Parabolic Equations in One Dimension** By combining the techniques applied to initial value problems and boundary value problems it

is possible to easily solve parabolic equations in one dimension. The method is often called the method of lines. It is illustrated here using the finite difference method, but the Galerkin finite element method and the orthogonal collocation method can also be combined with initial value methods in similar ways. The analysis is done by example. The finite volume method is described under Hyperbolic Equations.

**Example** Consider the diffusion equation, with boundary and initial conditions.

$$\frac{\partial c}{\partial t} = D \frac{\partial^2 c}{\partial x^2}$$

$$c(x, 0) = 0$$

$$c(0, t) = 1, \quad c(1, t) = 0$$

We denote by  $c_i$  the value of  $c(x_i, t)$  at any time. Thus,  $c_i$  is a function of time, and differential equations in  $c_i$  are ordinary differential equations. By evaluating the diffusion equation at the  $i$ th node and replacing the derivative with a finite difference equation, the following working equation is derived for each node  $i, i = 2, \dots, n$  (see Fig. 3-50).

$$\frac{dc_i}{dt} = D \frac{c_{i+1} - 2c_i + c_{i-1}}{\Delta x^2}$$

This can be written in the general form of a set of ordinary differential equations by defining the matrix  $\mathbf{AA}$ .

$$\frac{dc}{dt} = \mathbf{AA}c$$

This set of ordinary differential equations can be solved using any of the standard methods, and the stability of the integration of these equations is governed by the largest eigenvalue of  $\mathbf{AA}$ . When Euler's method is used to integrate in time, the equations become

$$\frac{c_i^{n+1} - c_i^n}{\Delta t} = D \frac{c_{i+1}^n - 2c_i^n + c_{i-1}^n}{\Delta x^2}$$

where  $c_i^n = c(x_i, t^n)$ . Notice that if the solution is known at every point at one time  $n$ , then it is a straightforward calculation to find the solution at every point at the new time  $n+1$ .

If Euler's method is used for integration, the time step is limited by

$$\Delta t \leq \frac{2}{|\lambda|_{\max}}$$

whereas if the Runge-Kutta-Feldberg method is used, the 2 in the numerator is replaced by 3.0. The largest eigenvalue of  $\mathbf{AA}$  is bounded by Gerschgorin's Theorem.

$$|\lambda|_{\max} \leq \max_{2 < j < n} \sum_{i=2}^n |\mathbf{AA}_{ji}| = \frac{4D}{\Delta x^2}$$

This gives the well-known stability limit

$$\Delta t \frac{D}{\Delta x^2} \leq \frac{1}{2}$$

The smallest eigenvalue is independent of  $\Delta x$  (it is  $D\pi^2/L^2$ ) so that the ratio of largest to smallest eigenvalue is proportional to  $1/\Delta x^2$ . Thus, the problem becomes stiff as  $\Delta x$  approaches zero. See Eq. (3-79).

The effect of the increased stiffness is that a smaller and smaller time step ( $\Delta t$ ) must be taken as the mesh is refined ( $\Delta x^2 \rightarrow 0$ ). At the same time, the number of points is increasing, so that the computation becomes very lengthy. Implicit methods are used to overcome this problem.

Write a finite difference form for the time derivative and average the right-hand sides, evaluated at the old and new time.

$$\frac{c_i^{n+1} - c_i^n}{\Delta t} = D(1 - \theta) \frac{c_{i+1}^n - 2c_i^n + c_{i-1}^n}{\Delta x^2} + D\theta \frac{c_{i+1}^{n+1} - 2c_i^{n+1} + c_{i-1}^{n+1}}{\Delta x^2}$$

Now the equations are of the form

$$-\frac{D\Delta t\theta}{\Delta x^2} c_{i+1}^{n+1} + \left[ 1 + 2\frac{D\Delta t\theta}{\Delta x^2} \right] c_i^{n+1} - \frac{D\Delta t\theta}{\Delta x^2} c_{i-1}^{n+1}$$

$$= c_i^n + \frac{D\Delta t(1 - \theta)}{\Delta x^2} (c_{i+1}^n - 2c_i^n + c_{i-1}^n)$$

and require solving a set of simultaneous equations, which have a tridiagonal structure. Using  $\theta = 0$  gives the Euler method (as above),

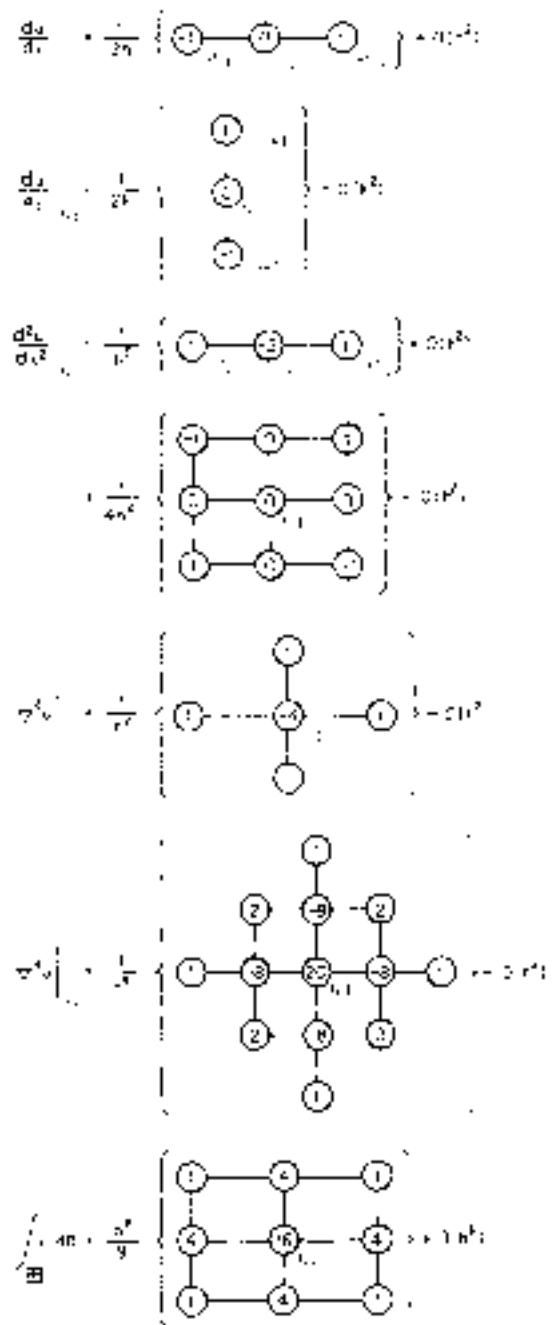

FIG. 3-50 Computational molecules.  $h = \Delta x = \Delta y$ .

$\theta = 0.5$  gives the Crank-Nicolson method, and  $\theta = 1$  gives the backward Euler method. The Crank-Nicolson method is also the same as applying the trapezoid rule to do the integration. The stability limit is given by

$$\frac{D\Delta t}{\Delta x^2} \leq \frac{0.5}{1 - 2\theta}$$

The price of using implicit methods is that one now has a system of equations to solve at each time step, and the solution methods are more complicated (particularly for nonlinear problems) than the straightforward explicit methods. Phenomena that happen quickly can also be obliterated or smoothed over by using a large time step, so implicit methods are not suitable in all cases. The engineer must decide if he or she wants to track those fast phenomena, and choose an appropriate method that handles the time scales that are important in the problem.

Other methods can be used in space, such as the finite element method, the orthogonal collocation method, or the method of orthogonal collocation on finite elements. One simply combines the methods for ordinary differential equations (see “Ordinary Differential Equations—Boundary Value Problems”) with the methods for initial-value problems (see “Numerical Solution of Ordinary Differential Equations as Initial Value Problems”). Fast Fourier transforms can also be used on regular grids (see “Fast Fourier Transform”).

**Elliptic Equations** Elliptic equations can be solved with both finite difference and finite element methods. One-dimensional elliptic problems are two-point boundary value problems. Two- and three-dimensional elliptic problems are often solved with iterative methods when the finite difference method is used and direct methods when the finite element method is used. So there are two aspects to consider: how the equations are discretized to form sets of algebraic equations and how the algebraic equations are then solved.

The prototype elliptic problem is steady-state heat conduction or diffusion,

$$k \left( \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right) = Q$$

possibly with a heat generation term per unit volume,  $Q$ . The boundary conditions taken here are  $T = f(x, y)$  on the boundary ( $S$ ) with  $f$  a known function. Illustrations are given for constant thermal conductivity  $k$  while  $Q$  is a known function of position. The finite difference formulation is given using the following nomenclature:

$$T_{i,j} = T(i\Delta x, j\Delta y)$$

The finite difference formulation is then (see Fig. 3-50)

$$\frac{T_{i+1,j} - 2T_{i,j} + T_{i-1,j}}{\Delta x^2} + \frac{T_{i,j+1} - 2T_{i,j} + T_{i,j-1}}{\Delta y^2} = Q_{i,j} \quad (3-83)$$

$$T_{i,j} = f(x_i, y_j) \text{ on } S$$

If the boundary is parallel to a coordinate axis any derivative is evaluated as in the section on boundary value problems, using either a one-sided, centered difference or a false boundary. If the boundary is more irregular and not parallel to a coordinate line then more complicated expressions are needed and the finite element method may be the better method.

Equation (3-83) provides a set of linear equations that must be solved. These equations and their boundary conditions may be written in matrix form as

$$\mathbf{A}\mathbf{t} = \mathbf{f}$$

where  $\mathbf{t}$  is the set of temperatures at all the points,  $\mathbf{f}$  is the set of heat generation terms at all points, and  $\mathbf{A}$  is formed from the coefficients of  $T_{ij}$  in Eq. (3-83). The solution can be obtained simply by solving the set of linear equations. For three-dimensional problems, the matrix  $\mathbf{A}$  is sparse, and iterative methods are used. These include Gauss-Seidel, alternating direction, overrelaxation methods, conjugate gradient, and multigrid methods. In Gauss-Seidel methods, one writes the equation for  $T_{ij}$  in terms of the other temperatures and cycles through all the points over and over. In the alternating direction method, one solves along one line (that is,  $x = \text{constant}$ ), keeping the side values fixed, and then repeats this for all lines, and then repeats the process. Multigrid methods solve the problem on successively refined grids, which has advantages for both convergence and error estimation. Conjugate gradient methods frequently use a preconditioned matrix. The equation is multiplied by another matrix, which is chosen so that the resulting problem is easier to solve than the original one. Finding such matrices

is an art, but it can speed convergence. The generalized minimal residual method is described in <http://mathworld.wolfram.com/GeneralizedMinimalResidualMethod.html>. Additional resources can be found at [http://www.netlib.org/linalg/html\\_templates/Templates.html](http://www.netlib.org/linalg/html_templates/Templates.html). When the problem is nonlinear, the iterative methods may not converge, or the mesh may have to be refined before they converge, so some experimentation is sometimes necessary.

Spreadsheets can be used to solve two-dimensional problems on rectangular grids. The equation for  $T_{ij}$  is obtained by rearranging Eq. (3-83).

$$2 \left( 1 + \frac{\Delta x^2}{\Delta y^2} \right) T_{i,j} = T_{i+1,j} + T_{i-1,j} + \frac{\Delta x^2}{\Delta y^2} (T_{i,j+1} + T_{i,j-1}) - \Delta x^2 \frac{Q_{i,j}}{k}$$

This equation is inserted into a cell and copied throughout the space represented by all the cells; when the iteration feature is turned on, the solution is obtained.

The Galerkin finite element method (FEM) is useful for solving elliptic problems and is particularly effective when the domain or geometry is irregular. As an example, cover the domain with triangles and define a trial function on each triangle. The trial function takes the value 1.0 at one corner and 0.0 at the other corners and is linear in between. See Fig. 3-51. These trial functions on each triangle are pieced together to give a trial function on the whole domain. General treatments of the finite element method are available (see references). The steps in the solution method are similar to those described for boundary value problems, except now the problems are much bigger so that the numerical analysis must be done very carefully to be efficient. Most engineers, though, just use a finite element program without generating it. There are three major caveats that must be addressed. The first one is that the solution is dependent on the mesh laid down, and the only way to assess the accuracy of the solution is to solve the problem with a more refined mesh. The second concern is that the solution obeys the shape of the trial function inside the element. Thus, if linear functions are used on triangles, a three-dimensional view of the solution, plotting the solution versus  $x$  and  $y$ , consists of a series of triangular planes joined together at the edges, as in a geodesic dome. The third caveat is that the Galerkin finite element method is applied to both the differential equations and the boundary conditions. Computer programs are usually quite general and may allow the user to specify boundary conditions that are not realistic. Also, natural boundary conditions are satisfied if no other boundary condition (ones involving derivatives) is set at a node. Thus, the user of finite element codes must be very clear what boundary conditions and differential equations are built into the computer code. When the problem is nonlinear, the Newton-Raphson method is used to iterate from an initial guess. Nonlinear problems lead to complicated integrals to evaluate, and they are usually evaluated using Gaussian quadrature.

One nice feature of the finite element method is the use of natural boundary conditions. It may be possible to solve the problem on a domain that is shorter than needed to reach some limiting condition (such as at an outflow boundary). The externally applied flux is still applied at the shorter domain, and the solution *inside* the truncated domain is still valid. Examples are given in Chang, M. W., and B. A. Finlayson, *Int. J. Num. Methods Eng.* **15**, 935–942 (1980), and Finlayson, B. A. (1992). The effect of this is to allow solutions in domains that are smaller, thus saving computation time and permitting the solution in semi-infinite domains.

The trial functions in the finite element method are not limited to linear ones. Quadratic functions and even higher-order functions are frequently used. The same considerations hold as for boundary value problems: The higher-order trial functions converge faster, but require more work. It is possible to refine both the mesh  $h$  and the power of polynomial in the trial function  $p$  in an  $hp$  method. Some problems have constraints on some of the variables. For flow problems, the pressure must usually be approximated by using a trial function that is one order lower than the polynomial used to approximate the velocity.

**Hyperbolic Equations** The most common situation yielding hyperbolic equations involves unsteady phenomena with convection. Two typical equations are the convective diffusive equation

$$\frac{\partial c}{\partial t} + u \frac{\partial c}{\partial x} = D \frac{\partial^2 c}{\partial x^2}$$

and the chromatography equation.

FIG. 3-51 Trial functions for Galerkin finite element method: linear polynomial on triangle.

(See “Partial Differential Equations.”) If the diffusion coefficient is zero, the convective diffusion equation is hyperbolic. If  $D$  is small, the phenomenon may be essentially hyperbolic, even though the equations are parabolic. Thus the numerical methods for hyperbolic equations may be useful even for parabolic equations.

Equations for several methods are given here, as taken from the book by Finlayson [Finlayson, B. A. (1992)]. If the convective term is treated with a centered difference expression, the solution exhibits oscillations from node to node, and these only go away if a very fine grid is used. The simplest way to avoid the oscillations with a hyperbolic equation is to use upstream derivatives. If the flow is from left to right, this would give

$$\frac{dc_i}{dt} + u \frac{c_i - c_{i-1}}{\Delta x} = D \frac{c_{i+1} - 2c_i + c_{i-1}}{\Delta x^2}$$

The effect of using upstream derivatives is to add artificial or numerical diffusion to the model. This can be ascertained by rearranging the finite difference form of the convective diffusion equation

$$\frac{dc_i}{dt} + u \frac{c_{i+1} - c_{i-1}}{2\Delta x} = \left( D + \frac{u\Delta x}{2} \right) \frac{c_{i+1} - 2c_i + c_{i-1}}{\Delta x^2}$$

Thus the diffusion coefficient has been changed from

$$D \text{ to } D + \frac{u\Delta x}{2}$$

Alternatively, the diffusion coefficient has been multiplied by the factor

$$D' = D \left( 1 + \frac{u\Delta x}{2D} \right) = D \left( 1 + \frac{Pe_{cell}}{2} \right)$$

where  $Pe_{cell} = \frac{u\Delta x}{D} = \frac{uL}{D} \frac{\Delta x}{L} = Pe \frac{\Delta x}{L}$  is called the cell Peclet number.

When the diffusion coefficient is very small (or diffusion is slow compared with convection), the Peclet number will be large. In that case, extraneous diffusion will be included in the solution unless the mesh size (denoted by  $\Delta x$ ) is small compared with the characteristic length of the problem. To avoid this problem (by keeping the factor small), very fine meshes must be used, and the smaller the diffusion coefficient, the smaller the required mesh size.

A variety of other methods are used to obtain a good solution without using extremely fine meshes. The flux correction methods keep track of the flux of material into and out of a cell (from one node to another) and put limits on the flux to make sure that no more material

FIG. 3-52 Nomenclature for finite volume method.

leaves the cell than is there originally plus the input amount. See Finlayson, *ibid.*, for many examples.

All the methods have a limit to the time step that is set by the convection term. Essentially, the time step should not be so big as to take the material farther than it can go at its velocity. This is usually expressed as a Courant number limitation.

$$Co = \frac{u\Delta t}{\Delta x} \leq 1$$

Some methods require a smaller limit, depending upon the amount of diffusion present (see Finlayson, *ibid.*, Appendix).

In the finite element method, Petrov-Galerkin methods are used to minimize the unphysical oscillations. The Petrov-Galerkin method essentially adds a small amount of diffusion in the flow direction to smooth the unphysical oscillations. The amount of diffusion is usually proportional to  $\Delta x$  so that it becomes negligible as the mesh size is reduced. The value of the Petrov-Galerkin method lies in being able to obtain a smooth solution when the mesh size is large, so that the computation is feasible. This is not so crucial in one-dimensional problems, but it is essential in two- and three-dimensional problems and purely hyperbolic problems.

**Finite Volume Methods** Finite volume methods are utilized extensively in computational fluid dynamics. In this method, a mass balance is made over a cell, accounting for the change in what is in the cell, and the flow in and out. Figure 3-52 illustrates the geometry of the  $i$ th cell. A mass balance made on this cell (with area  $A$  perpendicular to the paper) is

$$A \Delta x (c_i^{n+1} - c_i^n) = \Delta t A (J_{i-1/2} - J_{i+1/2})$$

where  $J$  is the flux due to convection and diffusion, positive in the  $+x$  direction.

$$J = uc - D \frac{\partial c}{\partial x}, \quad J_{i-1/2} = u_{i-1/2} c_{i-1/2} - D \frac{c_i - c_{i-1}}{\Delta x}$$

The concentration at the edge of the cell is taken as

$$c_{i-1/2} = \frac{1}{2}(c_i + c_{i-1})$$

Rearrangement for the case when the velocity  $u$  is the same for all nodes gives

$$\frac{c_i^{n+1} - c_i^n}{\Delta t} + \frac{u(c_{i+1} - c_{i-1})}{2\Delta x} = \frac{D}{\Delta x^2} (c_{i+1} - 2c_i + c_{i-1})$$

This is the same equation obtained by using the finite difference method. This isn't always true, and the finite volume equations are easy to derive. In two and three dimensions, the mesh need not be rectangular, as long as it is possible to compute the velocity normal to an edge of the cell. The finite volume method is useful for applications involving filling, such as injection molding, when only part of the cell is filled with fluid. Such applications do involve some approximations, since the interface is not tracked precisely, but they are useful engineering approximations.

**Parabolic Equations in Two or Three Dimensions** Computations become much more lengthy when there are two or more spatial dimensions. For example, we may have the unsteady heat conduction equation

$$\rho C_p \frac{\partial T}{\partial t} = k \left( \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2} \right) - Q$$

Most engineers use computer packages to solve such problems. If there is both convection and diffusion in the problem, the same considerations apply: A fine mesh is needed when the Peclet number is large. The upstream weighting and Petrov-Galerkin methods can be used, but it is important to apply the smoothing only in the direction of flow, since smoothing in the direction transverse to the flow direction would be incorrect. Some transverse smoothing is unavoidable, but the engineer needs to be sure that the smoothing is just enough to allow a good solution without creating large errors.

**Computer Software** When you are choosing computer software to solve your problem, there are a number of important considerations. The first decision is whether to use an approximate, engineering flow model, developed from correlations, or to solve the partial differential equations that govern the problem. Correlations are quick and easy to apply, but they may not be appropriate to your problem or give the needed detail. When you are using a computer package to solve partial differential equations, the first task is always to generate a mesh covering the problem domain. This is not a trivial task, and special methods have been developed to permit importation of a geometry from a computer-aided design (CAD) program. Then the mesh must be created automatically. If the boundary is irregular, the finite element method is especially well suited, although special embedding techniques can be used in finite difference methods (which are designed to be solved on rectangular meshes). Another capability to consider is the ability to track free surfaces that move during the computation. This phenomenon introduces the same complexity that occurs in problems with a large Peclet number, with the added difficulty that the free surface moves between mesh points and improper representation can lead to unphysical oscillations. The method used to solve the equations is important, and both explicit and implicit methods (as described above) can be used. Implicit methods may introduce unacceptable extra diffusion, so the engineer needs to examine the solution carefully. The methods used to smooth unphysical oscillations from node to node are also important, and the engineer needs to verify that the added diffusion or smoothing does not give inaccurate solutions. Since current-day problems are mostly nonlinear, convergence is always an issue since the problems are solved iteratively. Robust programs provide several methods for convergence, each of which is best in some circumstance or other. It is wise to have a program that includes many iterative methods. If the iterative solver is not very robust, the only recourse to solving a steady-state problem may be to integrate the time-dependent problem to steady state. The solution time may be long, and the final result may be further from convergence than would be the case if a robust iterative solver were used.

A variety of computer programs are available on the Internet, some free. First consider general-purpose programs. On the NIST web page <http://gams.nist.gov/>, choose "problem decision tree" then "differential and integral equations" and then "partial differential equations." The programs are organized by type of problem (elliptic, parabolic, and hyperbolic) and by the number of spatial dimensions (one or more than one). On the Netlib web site <http://www.netlib.org/>, search on "partial differential equation." Lau (1994, 2004) provides many programs in C++ (also see <http://www.nr.com/>). The multiphysics program Comsol Multiphysics (formerly FEMLAB) (<http://www.comsol.com/>), and ANSYS (<http://www.ansys.com/>). Of these, Comsol Multiphysics is particularly useful because it has a convenient graphical-user interface, permits easy mesh generation and refinement (including adaptive mesh refinement), allows the user to add phenomena and equations easily, permits solution by continuation methods (thus enhancing

Computational fluid dynamics (CFD) programs are more specialized, and most have been designed to solve sets of equations that are appropriate to specific industries. They can then include approximations and correlations for some features that would be difficult to solve for directly. Four major packages widely used are Fluent (<http://www.fluent.com/>), CFX (now part of ANSYS), Comsol Multiphysics (formerly FEMLAB) (<http://www.comsol.com/>), and ANSYS (<http://www.ansys.com/>). Of these, Comsol Multiphysics is particularly useful because it has a convenient graphical-user interface, permits easy mesh generation and refinement (including adaptive mesh refinement), allows the user to add phenomena and equations easily, permits solution by continuation methods (thus enhancing

convergence), and has extensive graphical output capabilities. Other packages are also available (see <http://cfd-online.com/>), and these may contain features and correlations specific to the engineer's industry. One important point to note is that for turbulent flow, all the programs contain approximations, using the  $k$ -epsilon models of turbulence, or large eddy simulations; the direct numerical simulation of turbulence is too slow to apply to very big problems, although it does give insight (independent of any approximations) that is useful for interpreting turbulent phenomena. Thus, the method used to include those turbulent correlations is important, and the method also may affect convergence or accuracy.

**FAST FOURIER TRANSFORM**

The Fourier transform and inverse transform are

$$Y(\omega) = \int_{-\infty}^{\infty} y(t)e^{i\omega t} dt$$

$$y(t) = \frac{1}{2\pi} \int_{-\infty}^{\infty} Y(\omega)e^{-i\omega t} d\omega$$

Suppose a signal  $y(t)$  is sampled at equal intervals

$$y_n = y(n\Delta), \quad n = \dots, -2, -1, 0, 1, 2, \dots$$

$\Delta =$  sampling interval (e.g., time between samples)

The Nyquist critical frequency or critical angular frequency is

$$f_c = \frac{1}{2\Delta}, \quad \omega_c = \frac{\pi}{\Delta}$$

If a function  $y(t)$  is bandwidth-limited to frequencies smaller than  $f_c$ , such as

$$Y(\omega) = 0 \quad \text{for } \omega > \omega_c$$

then the function is completely determined by its samples  $y_n$ . Thus, the entire information content of a signal can be recorded by sampling at a rate  $\Delta^{-1} = 2f_c$ . If the function is *not* bandwidth-limited, then aliasing occurs. Once a sample rate  $\Delta$  is chosen, information corresponding to frequencies greater than  $f_c$  is simply aliased into that range. The way to detect this in a Fourier transform is to see if the transform approaches zero at  $\pm f_c$ ; if not, aliasing has occurred, and a higher sampling rate is needed.

Next, suppose we have  $N$  samples, where  $N$  is even

$$y_k = y(t_k) \quad t_k = k\Delta \quad k = 0, 1, 2, \dots, N-1$$

and the sampling interval is  $\Delta$ . With only  $N$  values  $\{y_k\}$ , it is not possible to determine the complete Fourier transform  $Y(\omega)$ . We calculate the value  $Y(\omega_n)$  at the discrete points

$$\omega_n = \frac{2\pi n}{N\Delta}, \quad n = -\frac{N}{2}, \dots, 0, \dots, \frac{N}{2}$$

$$Y_n = \sum_{k=0}^{N-1} y_k e^{2\pi i k n / N}$$

$$Y(\omega_n) = \Delta Y_n$$

The discrete inverse Fourier transform is

$$y_k = \frac{1}{N} \sum_{n=0}^{N-1} Y_n e^{-2\pi i k n / N}$$

The fast Fourier transform (FFT) is used to calculate the Fourier transform as well as the inverse Fourier transform. A discrete Fourier transform of length  $N$  can be written as the sum of two discrete Fourier transforms, each of length  $N/2$ .

$$Y_k = Y_k^e + W^k Y_k^o$$

Here  $Y_k$  is the  $k$ th component of the Fourier transform of  $y$ , and  $Y_k^e$  is the  $k$ th component of the Fourier transform of the even components

of  $\{y_j\}$  and is of length  $N/2$ . Similarly,  $Y_k^o$  is the  $k$ th component of the Fourier transform of the odd components of  $\{y_j\}$  and is of length  $N/2$ .  $W$  is a constant, which is taken to the  $k$ th power.

$$W = e^{2\pi i / N}$$

Since  $Y_k$  has  $N$  components, while  $Y_k^e$  and  $Y_k^o$  have  $N/2$  components,  $Y_k^e$  and  $Y_k^o$  are repeated once to give  $N$  components in the calculation of  $Y_k$ . This decomposition can be used recursively. Thus,  $Y_k^e$  is split into even and odd terms of length  $N/4$ .

$$Y_k^e = Y_k^{ee} + W^k Y_k^{eo}$$

$$Y_k^o = Y_k^{oe} + W^k Y_k^{oo}$$

This process is continued until there is only one component. For this reason, the number  $N$  is taken as a power of 2. The vector  $\{y_j\}$  is filled with zeroes, if need be, to make  $N = 2^p$  for some  $p$ . The standard Fourier transform takes  $N^2$  operations to calculate, whereas the fast Fourier transform takes only  $N \log_2 N$ . For large  $N$ , the difference is significant; at  $N = 100$  it is a factor of 15, but for  $N = 1000$  it is a factor of 100.

The discrete Fourier transform can also be used for differentiating a function, and this is used in the spectral method for solving differential equations [Gottlieb, D., and S. A. Orszag, *Numerical Analysis of Spectral Methods: Theory and Applications*, SIAM, Philadelphia (1977); Trefethen, L. N., *Spectral Methods in Matlab*, SIAM, Philadelphia (2000)]. Suppose we have a grid of equidistant points

$$x_n = n\Delta x, \quad n = 0, 1, 2, \dots, 2N-1, \quad \Delta x = \frac{L}{2N}$$

The solution is known at each of these grid points  $\{y(x_n)\}$ . First the discrete Fourier transform is taken:

$$Y_k = \frac{1}{2N} \sum_{n=0}^{2N-1} y(x_n) e^{-2ik\pi x_n / L}, \quad k = -N, -N+1, \dots, 0, \dots, N-1, N$$

The inverse transformation is

$$y(x) = \frac{1}{L} \sum_{k=-N}^N Y_k e^{2ik\pi x / L}$$

Differentiate this to get

$$\frac{dy}{dx} = \frac{1}{L} \sum_{k=-N}^N Y_k \frac{2\pi i k}{L} e^{2ik\pi x / L}$$

Thus at the grid points

$$\left. \frac{dy}{dx} \right|_n = \sum_{k=-N}^N Y_k \frac{2\pi i k}{L} e^{2ik\pi x_n / L}$$

The process works as follows. From the solution at all grid points the Fourier transform is obtained using FFT,  $\{Y_k\}$ . Then this is multiplied by  $2\pi i k / L$  to obtain the Fourier transform of the derivative.

$$Y'_k = Y_k \frac{2\pi i k}{L}$$

Then the inverse Fourier transform is taken using FFT, giving the value of the derivative at each of the grid points.

$$\left. \frac{dy}{dx} \right|_n = \frac{1}{L} \sum_{k=-N}^N Y'_k e^{2ik\pi x_n / L}$$

The spectral method is used for direct numerical simulation (DNS) of turbulence. The Fourier transform is taken of the differential equation, and the resulting equation is solved. Then the inverse transformation gives the solution. When there are nonlinear terms, they are calculated at each node in physical space, and the Fourier transform is taken of the result. This technique is especially suited to time-dependent problems, and the major computational effort is in the fast Fourier transform.

## OPTIMIZATION

## INTRODUCTION

Optimization is a key enabling tool for decision making in chemical engineering. It has evolved from a methodology of academic interest into a technology that continues to have a significant impact on engineering research and practice. Optimization algorithms form the core tools for (1) experimental design, parameter estimation, model development, and statistical analysis; (2) process synthesis analysis, design, and retrofit; (3) model predictive control and real-time optimization; and (4) planning, scheduling, and the integration of process operations into the supply chain.

As shown in Fig. 3-53, optimization problems that arise in chemical engineering can be classified in terms of continuous and discrete variables. For the former, nonlinear programming (NLP) problems form the most general case, and widely applied specializations include linear programming (LP) and quadratic programming (QP). An important distinction for NLP is whether the optimization problem is convex or nonconvex. The latter NLP problem may have multiple local optima, and an important question is whether a global solution is required for the NLP. Another important distinction is whether the problem is assumed to be differentiable or not.

Mixed integer problems also include discrete variables. These can be written as mixed integer nonlinear programs (MINLP), or as mixed integer linear programs (MILP), if all variables appear linearly in the constraint and objective functions. For the latter an important case occurs when all the variables are integer; this gives rise to an integer programming (IP) problem. IP problems can be further classified into many special problems (e.g., assignment, traveling salesperson, etc.), which are not shown in Fig. 3-53. Similarly, the MINLP problem also gives rise to special problem classes, although here the main distinction is whether its relaxation is convex or nonconvex.

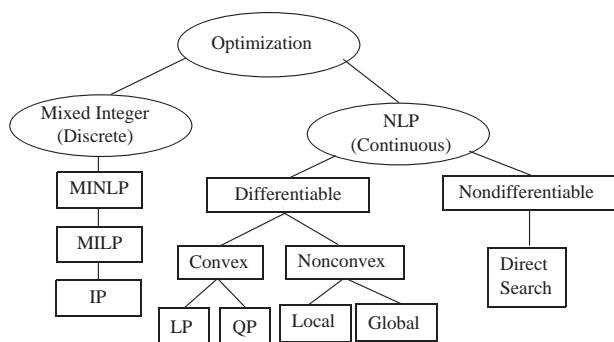

FIG. 3-53 Classes of optimization problems and algorithms.

The ingredients of formulating optimization problems include a mathematical model of the system, an objective function that quantifies a criterion to be extremized, variables that can serve as decisions, and, optionally, inequality constraints on the system. When represented in algebraic form, the general formulation of discrete/continuous optimization problems can be written as the following mixed integer optimization problem:

$$\begin{aligned} \text{Min } & f(x, y) \\ \text{subject to } & h(x, y) = 0 \\ & g(x, y) \leq 0 \\ & x \in \mathfrak{R}_n, y \in \{0, 1\} \end{aligned} \quad (3-84)$$

where  $f(x, y)$  is the objective function (e.g., cost, energy consumption, etc.),  $h(x, y) = 0$  are the equations that describe the performance of the system (e.g., material balances, production rates), and the inequality constraints  $g(x, y) \leq 0$  can define process specifications or constraints for feasible plans and schedules. Note that the operator  $\max f(x)$  is equivalent to  $\min [-f(x)]$ . We define the real  $n$  vector  $x$  to represent the continuous variables while the  $t$  vector  $y$  represents the discrete variables, which, without loss of generality, are often restricted to take values of 0 or 1 to define logical or discrete decisions, such as assignment of equipment and sequencing of tasks. (These variables can also be formulated to take on other integer values as well.) Problem (3-84) corresponds to a mixed integer nonlinear program when any of the functions involved are nonlinear. If all functions are linear, it corresponds to a mixed integer linear program. If there are no 0–1 variables, then problem (3-84) reduces to a nonlinear program (3-85) or linear program (3-97) depending on whether the functions are linear.

We start with continuous variable optimization and consider in the next section the solution of NLP problems with differentiable objective and constraint functions. If only local solutions are required for the NLP problem, then very efficient large-scale methods can be considered. This is followed by methods that are not based on local optimality criteria; we consider direct search optimization methods that do not require derivatives as well as deterministic global optimization methods. Following this, we consider the solution of mixed integer problems and outline the main characteristics of algorithms for their solution. Finally, we conclude with a discussion of optimization modeling software and its implementation on engineering models.

## GRADIENT-BASED NONLINEAR PROGRAMMING

For continuous variable optimization we consider (3-84) without discrete variable  $y$ . The general NLP problem (3-85) is presented here:

$$\begin{aligned} \text{Min } & f(x) \\ \text{subject to } & h(x) = 0 \\ & g(x) \leq 0 \end{aligned} \quad (3-85)$$

and we assume that the functions  $f(x)$ ,  $h(x)$ , and  $g(x)$  have continuous first and second derivatives. A key characteristic of (3-85) is whether the problem is convex or not, i.e., whether it has a convex objective function and a convex feasible region. A function  $\phi(x)$  of  $x$  in some domain  $X$  is convex if and only if for all points  $x_1, x_2 \in X$

$$\phi[\alpha x_1 + (1 - \alpha)x_2] \leq \alpha\phi[x_1 + (1 - \alpha)x_2] + (1 - \alpha)\phi(x_2) \quad (3-86)$$

holds for all  $\alpha \in (0, 1)$ . [Strict convexity requires that the inequality (3-86) be strict.] Convex feasible regions require  $g(x)$  to be a convex function and  $h(x)$  to be linear. If (3-85) is a convex problem, then any local solution is guaranteed to be a global solution to (3-85). Moreover, if the objective function is strictly convex, then this solution  $x^*$  is unique. On the other hand, nonconvex problems may have multiple local solutions, i.e., feasible solutions that minimize the objective function within some neighborhood about the solution.

We consider first methods that find only local solutions to nonconvex problems, as more difficult (and expensive) search procedures are required to find a global solution. Local methods are currently very

efficient and have been developed to deal with very large NLP problems. Moreover, by considering the structure of convex NLP problems (including LP and QP problems), even more powerful methods can be applied. To study these methods, we first consider conditions for local optimality.

**Local Optimality Conditions: A Kinematic Interpretation**  
 Instead of a formal development of conditions that define a local optimum, we present a more intuitive kinematic illustration. Consider the contour plot of the objective function  $f(x)$ , given in Fig. 3-54, as a smooth valley in space of the variables  $x_1$  and  $x_2$ . For the contour plot of this unconstrained problem  $\text{Min } f(x)$ , consider a ball rolling in this valley to the lowest point of  $f(x)$ , denoted by  $x^*$ . This point is at least a local minimum and is defined by a point with a zero gradient and at least nonnegative curvature in all (nonzero) directions  $p$ . We use the first-derivative (*gradient*) vector  $\nabla f(x)$  and second-derivative (*Hessian*) matrix  $\nabla_{xx} f(x)$  to state the necessary first- and second-order conditions for unconstrained optimality:

$$\nabla_x f(x^*) = 0 \quad p^T \nabla_{xx} f(x^*) p \geq 0 \quad \text{for all } p \neq 0 \quad (3-87)$$

These necessary conditions for local optimality can be strengthened to sufficient conditions by making the inequality in (3-87) strict (i.e., positive curvature in all directions). Equivalently, the sufficient (necessary) curvature conditions can be stated as follows:  $\nabla_{xx} f(x^*)$  has all positive (nonnegative) eigenvalues and is therefore defined as a positive (semidefinite) definite matrix.

Now consider the imposition of inequality [ $g(x) \leq 0$ ] and equality constraints [ $h(x) = 0$ ] in Fig. 3-55. Continuing the kinematic interpretation, the inequality constraints  $g(x) \leq 0$  act as “fences” in the valley, and equality constraints  $h(x) = 0$  act as “rails.” Consider now a ball, constrained on a rail and within fences, to roll to its lowest point. This stationary point occurs when the normal forces exerted by the fences [ $-\nabla g(x^*)$ ] and rails [ $-\nabla h(x^*)$ ] on the ball are balanced by the force of gravity [ $-\nabla f(x^*)$ ]. This condition can be stated by the following *Karush-Kuhn-Tucker (KKT) necessary conditions* for constrained optimality:

**Balance of Forces** It is convenient to define the  $L$  function  $L(x, \lambda, \nu) = f(x) + g(x)^T \lambda + h(x)^T \nu$ , along with “weights” or multipliers  $\lambda$  and  $\nu$  for the constraints. The stationarity condition (balance of forces acting on the ball) is then given by

$$\nabla L(x, \lambda, \nu) = \nabla f(x) + \nabla h(x)\lambda + \nabla g(x)\nu = 0 \quad (3-88)$$

**Feasibility** Both inequality and equality constraints must be satisfied (ball must lie on the rail and within the fences):

$$h(x) = 0, \quad g(x) \leq 0 \quad (3-89)$$

**Complementarity** Inequality constraints are either strictly satisfied (active) or inactive, in which case they are irrelevant to the solu-

FIG. 3-54 Unconstrained minimum.

FIG. 3-55 Constrained minimum.

tion. In the latter case the corresponding KKT multiplier must be zero. This is written as

$$\nu^T g(x) = 0, \quad \nu \geq 0 \quad (3-90)$$

**Constraint Qualification** For a local optimum to satisfy the KKT conditions, an additional regularity condition is required on the constraints. This can be defined in several ways. A typical condition is that the active constraints at  $x^*$  be linearly independent; i.e., the matrix:  $[\nabla h(x^*) | \nabla g_A(x^*)]$  is full column rank, where  $g_A$  is the vector of inequality constraints with elements that satisfy  $g_{A,i}(x^*) = 0$ . With this constraint qualification, the KKT multipliers ( $\lambda, \nu$ ) are guaranteed to be unique at the optimal solution.

**Second-Order Conditions** As with unconstrained optimization, nonnegative (positive) curvature is necessary (sufficient) in all the allowable (i.e., constrained) nonzero directions  $p$ . The necessary second-order conditions can be stated as

$$p^T \nabla_{xx} L(x^*) p \geq 0 \quad \text{for all } p \neq 0, \nabla h(x^*)^T p = 0, \nabla g(x^*)^T p \geq 0, \nabla g_A(x^*)^T p = 0 \quad (3-91)$$

and the corresponding sufficient conditions require first the inequality in (3-91) to be strict. Note that for the example in Fig. 3-54, the allowable directions  $p$  span the entire space for  $x$  while in Fig. 3-55 there are *no* allowable directions  $p$ .

**Example** To illustrate the KKT conditions, consider the following unconstrained NLP problem:

$$\text{Min } (x_1)^2 - 4x_1 + 3/2 (x_2)^2 - 7x_2 + x_1 x_2 + 9 - \ln x_1 - \ln x_2 \quad (3-92)$$

corresponding to the contour plot in Fig. 3-54. The optimal solution can be found by solving for the first-order conditions (3-87):

$$\nabla f(x) = \begin{bmatrix} 2x_1 - 4 + x_2 - 1/x_1 \\ 3x_2 - 7 + x_1 - 1/x_2 \end{bmatrix} = 0 \Rightarrow x^* = \begin{bmatrix} 1.3475 \\ 2.0470 \end{bmatrix} \quad (3-93)$$

and  $f(x^*) = -2.8742$ . Checking the second-order conditions leads to

$$\begin{aligned} \nabla_{xx} f(x^*) &= \begin{bmatrix} 2 + 1/(x_1^*)^2 & 1 \\ 1 & 3 + 1/(x_2^*)^2 \end{bmatrix} \\ \Rightarrow \nabla_{xx} f(x^*) &= \begin{bmatrix} 2.5507 & 1 \\ 1 & 3.2387 \end{bmatrix} \quad (\text{positive definite}) \end{aligned} \quad (3-94)$$

Now consider the constrained NLP problems

$$\begin{aligned} \text{Min } (x_1)^2 - 4x_1 + 3/2(x_2)^2 - 7x_2 + x_1 x_2 + 9 - \ln x_1 - \ln x_2 \\ \text{subject to } 4 - x_1 x_2 \leq 0 \\ 2x_1 - x_2 = 0 \end{aligned} \quad (3-95)$$

that correspond to the plot in Fig. 3-54. The optimal solution can be found by

applying the first-order KKT conditions (3-88) to (3-90):

$$\begin{aligned} \nabla L(x, \lambda, v) &= \nabla f(x) + \nabla h(x)\lambda + \nabla g(x)v = \begin{bmatrix} 2x_1 - 4 + x_2 - 1/x_1 \\ 3x_2 - 7 + x_1 - 1/x_2 \end{bmatrix} \\ &\quad + \begin{bmatrix} 2 \\ -1 \end{bmatrix} \lambda + \begin{bmatrix} -x_2 \\ -x_1 \end{bmatrix} v = 0 \\ g(x) &= 4 - x_1x_2 \leq 0, \quad h(x) = 2x_1 - x_2 = 0 \\ g(x)v &= (4 - x_1x_2)v, \quad v \geq 0 \end{aligned} \tag{3-96}$$

$$\Downarrow$$

$$x^* = \begin{bmatrix} 1.4142 \\ 2.8284 \end{bmatrix}, \quad \lambda^* = 1.036, \quad v^* = 1.068$$

and  $f(x^*) = -1.8421$ . Checking the second-order conditions (3-91) leads to

$$\begin{aligned} \nabla_{xx}L(x^*, \lambda^*, v^*) &= \nabla_{xx}[f(x^*) + h(x^*)\lambda^* + g(x^*)v^*] = \begin{bmatrix} 2 + 1/(x_1)^2 & 1 - v \\ 1 - v & 3 + 1/(x_2)^2 \end{bmatrix} \\ &= \begin{bmatrix} 2.5 & 0.068 \\ 0.068 & 3.125 \end{bmatrix} \\ [\nabla h(x^*) \mid \nabla g_A(x^*)]^T p &= \begin{bmatrix} 2 & -2.8284 \\ -1 & -1.4142 \end{bmatrix}^T p = 0, \quad p \neq 0 \end{aligned}$$

However, note that because  $[\nabla h(x^*) \mid \nabla g_A(x^*)]$  is nonsingular, there are no nonzero vectors  $p$  that satisfy the allowable directions. Hence, the sufficient second-order conditions  $[p^T \nabla_{xx}L(x^*, \lambda^*, v^*)p > 0, \text{ for all allowable } p]$  are *vacuously satisfied* for this problem.

**Convex Cases of NLP Problems** Linear programs and quadratic programs are special cases of (3-85) that allow for more efficient solution, based on application of KKT conditions (3-88) through (3-91). Because these are convex problems, any locally optimal solution is a global solution. In particular, if the objective and constraint functions in (3-85) are linear, then the following linear program (LP)

$$\begin{aligned} \text{Min } & c^T x \\ \text{subject to } & Ax = b \\ & Cx \leq d \end{aligned} \tag{3-97}$$

can be solved in a finite number of steps, and the optimal solution lies at a vertex of the polyhedron described by the linear constraints. This is shown in Fig. 3-56, and in so-called primal degenerate cases, multiple vertices can be alternate optimal solutions, with the same values of the objective function. The standard method to solve (3-97) is the simplex method, developed in the late 1940s (see Dantzig, 1963) although, starting from Karmarkar's discovery in 1984, interior point methods have become quite advanced and competitive for highly constrained problems [Wright, S. J., *Primal-Dual Interior Point Methods*,

SIAM, Philadelphia (1996)]. The simplex method proceeds by moving successively from vertex to vertex with improved objective function values. Methods to solve (3-97) are well implemented and widely used, especially in planning and logistical applications. They also form the basis for MILP methods discussed later. Currently, state-of-the-art LP solvers can handle millions of variables and constraints, and the application of further decomposition methods leads to the solution of problems that are two or three orders of magnitude larger than this. See the general references of Hillier and Lieberman (1974) and Edgar et al. (2002) for more details. Also, the interior point method is described below from the perspective of more general NLP problems.

Quadratic programs (QPs) represent a slight modification of (3-97) and can be stated as

$$\begin{aligned} \text{Min } & c^T x + 1/2 x^T Q x \\ \text{subject to } & Ax = b \\ & Cx \leq d \end{aligned} \tag{3-98}$$

If the matrix  $Q$  is positive semidefinite (positive definite) when projected into the null space of the active constraints, then (3-98) is (strictly) convex and the QP is a global (and unique) minimum. Otherwise, local solutions exist for (3-98), and more extensive global optimization methods are needed to obtain the global solution. Like LPs, convex QPs can be solved in a finite number of steps. However, as seen in Fig. 3-57, these optimal solutions can lie on a vertex, on a constraint boundary, or in the interior. A number of active set strategies have been created that solve the KKT conditions of the QP and incorporate efficient updates of active constraints. Popular methods include null space algorithms, range space methods, and Schur complement methods. As with LPs, QP problems can also be solved with interior point methods [see Wright (1996)].

**Solving the General NLP Problem** Solution techniques for (3-85) deal with satisfaction of the KKT conditions (3-88) through (3-91). Many NLP solvers are based on successive quadratic programming (SQP) as it allows the construction of a number of NLP algorithms based on the Newton-Raphson method for equation solving (see "Numerical Analysis" section). SQP solvers have been shown to require the fewest function evaluations to solve NLP problems [Schittkowski, K., *Lecture Notes in Economics and Mathematical Systems*, no. 282, Springer-Verlag, Berlin (1987)], and they can be tailored to a broad range of process engineering problems with different structure.

The SQP strategy applies the equivalent of a Newton step to the KKT conditions of the nonlinear programming problem, and this leads to a fast rate of convergence. By adding slack variables  $s$ , the first-order KKT conditions can be rewritten as

$$\nabla f(x) + \nabla h(x)\lambda + \nabla g(x)v = 0 \tag{3-99a}$$

$$h(x) = 0 \tag{3-99b}$$

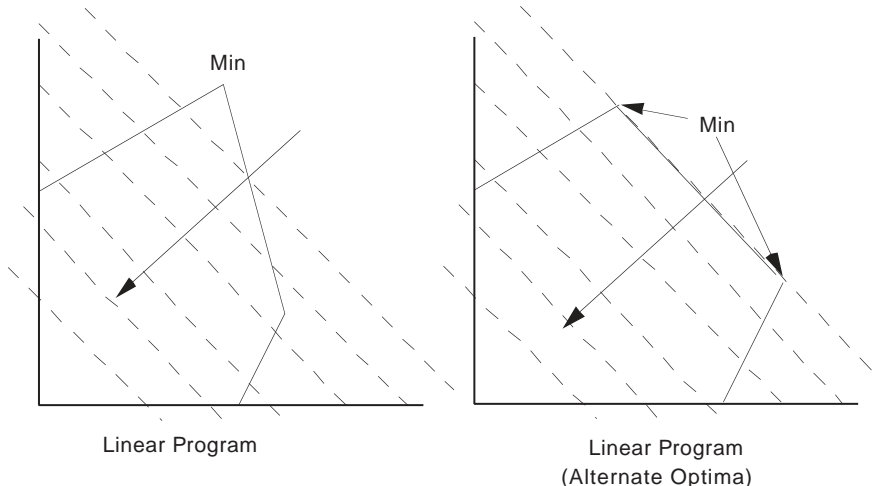

FIG. 3-56 Contour plots of linear programs.

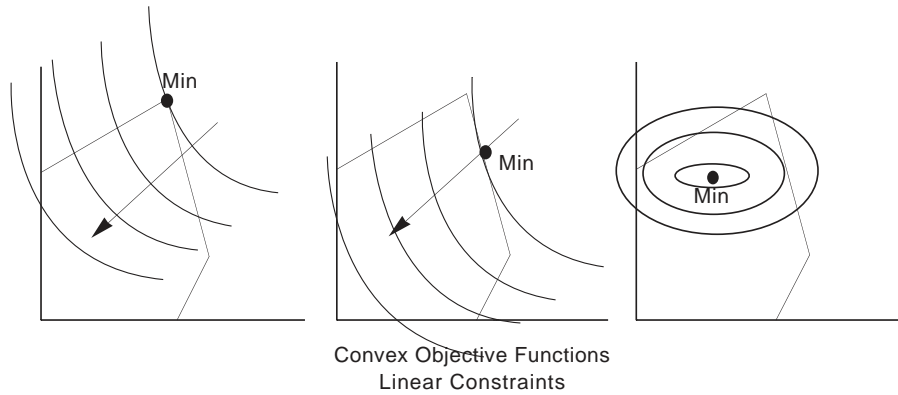

FIG. 3-57 Contour plots of convex quadratic programs.

$$g(x) + s = 0 \quad (3-99c)$$

$$Sve = 0 \quad (3-99d)$$

$$(s, v) \geq 0 \quad (3-99e)$$

where  $e = [1, 1, \dots, 1]^T$ ,  $S = \text{diag}\{s\}$ , and  $V = \text{diag}\{v\}$ . SQP methods find solutions that satisfy (3-99) by generating Newton-like search directions at iteration  $k$ . However, Eqs. (3-99d) and active bounds (3-99e) are dependent at the solution and serve to make the KKT system ill-conditioned near the solution. SQP algorithms treat these conditions in two ways. In the *active set strategy*, discrete decisions are made regarding the active constraint set  $i \in I = \{i | g_i(x^*) = 0\}$  and (3-99d) is replaced by  $s_i = 0$ ,  $i \in I$ , and  $v_i = 0$ ,  $i \notin I$ . Determining the active set is a combinatorial problem, and a straightforward way to determine an estimate of the active set [and to satisfy (3-99e)] is to formulate and solve, at a point  $x^k$ , the following QP at iteration  $k$ :

$$\begin{aligned} \text{Min } & \nabla f(x^k)^T p + 1/2 p^T \nabla_{xx} L(x^k, \lambda^k, v^k) p \\ \text{subject to } & h(x^k) + \nabla h(x^k)^T p = 0 \\ & g(x^k) + \nabla g(x^k)^T p + s = 0, \quad s \geq 0 \end{aligned} \quad (3-100)$$

The KKT conditions of (3-100) are given by

$$\nabla f(x^k) + \nabla^2 L(x^k, \lambda^k, v^k) p + \nabla h(x^k) \lambda + \nabla g(x^k) v = 0 \quad (3-101a)$$

$$h(x^k) + \nabla h(x^k)^T p = 0 \quad (3-101b)$$

$$g(x^k) + \nabla g(x^k)^T p + s = 0 \quad (3-101c)$$

$$Sve = 0 \quad (3-101d)$$

$$(s, v) \geq 0 \quad (3-101e)$$

where the Hessian of the Lagrange function  $\nabla_{xx} L(x, \lambda, v) = \nabla_{xx} [f(x) + h(x)^T \lambda + g(x)^T v]$  is calculated directly or through a quasi-Newton approximation (created by differences of gradient vectors). It is easy to show that (3-101a) through (3-101c) correspond to a Newton-Raphson step for (3-99a) through (3-99c) applied at iteration  $k$ . Also, selection of the active set is now handled at the QP level by satisfying the conditions (3-101d) and (3-101e). To evaluate and change candidate active sets, QP algorithms apply inexpensive matrix updating strategies to the KKT matrix associated with (3-100). Details of this approach can be found in Nocedal and Wright (1999) and Fletcher (1987).

As alternatives that avoid the combinatorial problem of selecting the active set, interior point (or barrier) methods modify the NLP problem (3-85) to form

$$\begin{aligned} \text{Min } & f(x^k) - \mu \sum_i \ln s_i \\ \text{subject to } & h(x^k) = 0 \\ & g(x^k) + s = 0 \end{aligned} \quad (3-102)$$

where the solution to (3-103) has  $s > 0$  for the penalty parameter  $\mu > 0$ , and decreasing  $\mu$  to 0 leads to solution of problem (3-85). The KKT conditions for this problem can be written as

$$\nabla f(x^*) + \nabla h(x^*) \lambda + \nabla g(x^*) v = 0$$

$$\begin{aligned} h(x^*) &= 0 \\ g(x^*) + s &= 0 \\ Sve &= \mu e \end{aligned} \quad (3-103)$$

and for  $\mu > 0$ ,  $s > 0$ , and  $v > 0$ , Newton steps generated to solve (3-103) are well behaved and analogous to (3-101), with a modification on the right-hand side of (3-101d). A detailed description of this algorithm, called IPOPT, can be found in Wächter and Biegler [*Math. Prog.* **106**(1), 25–57 (2006)].

Both active set and interior point methods possess clear tradeoffs. Interior point methods may require more iterations to solve (3-102) for various values of  $\mu$ , while active set methods require the solution of the more expensive QP subproblem (3-100). Thus, if there are few inequality constraints or an active set is known (say from a good starting guess, or a known QP solution from a previous iteration), then solving (3-100) is not expensive and the active set method is favored. On the other hand, for problems with many inequality constraints, interior point methods are often faster, as they avoid the combinatorial problem of selecting the active set. This is especially true for large-scale problems and when a large number of bounds are active. Examples that demonstrate the performance of these approaches include the solution of model predictive control (MPC) problems [Rao et al., *J. Optim. Theory Appl.* **99**:723 (1998); Albuquerque et al., *Comp. Chem. Eng.* **23**:283 (1997)] and the solution of large optimal control problems using barrier NLP solvers. For instance, IPOPT allows the solution of problems with more than 1,000,000 variables and up to 50,000 degrees of freedom [see Biegler et al., *Chem. Eng. Sci.* **57**(4):575–593 (2002); Laird et al., *ASCE J. Water Resource Management and Planning* **131**(2):125 (2005)].

**Other Gradient-Based NLP Solvers** In addition to SQP methods, a number of NLP solvers have been developed and adapted for large-scale problems. Generally these methods require more function evaluations than of SQP methods, but they perform very well when interfaced to optimization modeling platforms, where function evaluations are cheap. All these can be derived from the perspective of applying Newton steps to portions of the KKT conditions.

LANCELOT (Conn et al., 2000) is based on the solution of bound-constrained subproblems. Here an augmented Lagrangian is formed from (3-85) and the following subproblem is solved:

$$\begin{aligned} \text{Min } & f(x) + \lambda^T h(x) + v^T [g(x) + s] + 1/2 \rho \|h(x), g(x) + s\|^2 \\ \text{subject to } & s \geq 0 \end{aligned} \quad (3-104)$$

The above subproblem can be solved very efficiently for fixed values of the multipliers  $\lambda$  and  $v$  and penalty parameter  $\rho$ . Here a gradient projection trust region method is applied. Once subproblem (3-104) is solved, the multipliers and penalty parameter are updated in an outer loop and the cycle repeats until the KKT conditions for (3-85) are satisfied. LANCELOT works best when exact second derivatives are available. This promotes a fast convergence rate in solving each

subproblem and allows a bound-constrained trust region method to exploit directions of negative curvature in the Hessian matrix.

*Reduced gradient methods* are active set strategies that rely on partitioning the variables and solving (3-99) in a nested manner. Without loss of generality, problem (3-85) can be rewritten as  $\text{Min } f(z)$  subject to  $c(z) = 0$ ,  $a \leq z \leq b$ . Variables are partitioned as nonbasic variables (those fixed to their bounds), basic variables (those that can be solved from the equality constraints), and superbasic variables (those remaining variables between bounds that serve to drive the optimization); this leads to  $z^T = [z_N^T, z_B^T, z_S^T]$ . This partition is derived from local information and may change over the course of the optimization iterations. The corresponding KKT conditions can be written as

$$\nabla_N f(z) + \nabla_N c(z)\gamma = \beta_a - \beta_b \quad (3-105a)$$

$$\nabla_B f(z) + \nabla_B c(z)\gamma = 0 \quad (3-105b)$$

$$\nabla_S f(z) + \nabla_S c(z)\gamma = 0 \quad (3-105c)$$

$$c(z) = 0 \quad (3-105d)$$

$$z_{N,j} = a_j \text{ or } b_j, \quad \beta_{a,j} \geq 0, \quad \beta_{b,j} = 0 \text{ or } \beta_{b,j} \geq 0, \quad \beta_{a,j} = 0 \quad (3-105e)$$

where  $\gamma$  and  $\beta$  are the KKT multipliers for the equality and bound constraints, respectively, and (3-105e) replaces the complementarity conditions (3-90). Reduced gradient methods work by nesting equations (3-105b,d) within (3-105a,c). At iteration  $k$ , for fixed values of  $z_N^k$  and  $z_S^k$ , we can solve for  $z_B$  by using (3-105d) and for  $\gamma$  by using (3-105b). Moreover, linearization of these equations leads to sensitivity information (i.e., constrained derivatives or reduced gradients) that indicates how  $z_B$  changes with respect to  $z_S$  and  $z_N$ . The algorithm then proceeds by updating  $z_S$  by using reduced gradients in a Newton-type iteration to solve Eq. (3-105c). Following this, bound multipliers  $\beta$  are calculated from (3-105a). Over the course of the iterations, if the variables  $z_B$  or  $z_S$  exceed their bounds or if some bound multipliers  $\beta$  become negative, then the variable partition needs to be changed and Eqs. (3-105) are reconstructed. These reduced gradient methods are embodied in the popular GRG2, CONOPT, and SOLVER codes (Edgar et al., 2002). The SOLVER code has been incorporated into Microsoft Excel. CONOPT [Drud, A., *ORSA J. Computing* 6: 207–216 (1994)] is an efficient and widely used code in several optimization modelling environments.

MINOS (Murtagh and Saunders, Technical Report SOL 83-20R, Stanford University, 1987) is a well-implemented package that offers a variation on reduced gradient strategies. At iteration  $k$ , Eq. (3-105d) is replaced by its linearization

$$c(z_N^k, z_B^k, z_S^k) + \nabla_B c(z^k)^T (z_B - z_B^k) + \nabla_S c(z^k)^T (z_S - z_S^k) = 0 \quad (3-106)$$

and Eqs. (3-105a–c, e) are solved with (3-106) as a subproblem by using concepts from the reduced gradient method. At the solution of this subproblem, constraints (3-105d) are relinearized and the cycle repeats until the KKT conditions of (3-105) are satisfied. The augmented lagrangian function from (3-104) is used to penalize movement away from the feasible region. For problems with few degrees of freedom, the resulting approach leads to an extremely efficient method even for very large problems. MINOS has been interfaced to a number of modelling systems and enjoys widespread use. It performs especially well on large problems with few nonlinear constraints. However, on highly nonlinear problems it is usually less reliable than other reduced gradient methods.

**Algorithmic Details for NLP Methods** All the above NLP methods incorporate concepts from the Newton-Raphson method for equation solving. Essential features of these methods are that they provide (1) accurate derivative information to solve for the KKT conditions, (2) stabilization strategies to promote convergence of the Newton-like method from poor starting points, and (3) regularization of the Jacobian matrix in Newton's method (the so-called KKT matrix) if it becomes singular or ill-conditioned.

1. *NLP methods provide first and second derivatives.* The KKT conditions require first derivatives to define stationary points, so accurate first derivatives are essential to determine locally optimal solutions for differentiable NLPs. Moreover, Newton-Raphson methods that are applied to the KKT conditions, as well as the task of checking second-order KKT conditions, necessarily require second-

derivative information. (Note that second-order conditions are not checked by methods that do not use second derivatives.) With the recent development of automatic differentiation tools, many modeling and simulation platforms can provide exact first and second derivatives for optimization. When second derivatives are available for the objective or constraint functions, they can be used directly in LANCELOT as well as SQP and reduced gradient methods. Otherwise, on problems with few superbasic variables, both reduced gradient methods and SQP methods [with reduced gradient methods applied to the QP subproblem (3-100)] can benefit from positive definite quasi-Newton approximations [Nocedal and Wright (1999)] applied to reduced second-derivative quantities (the so-called reduced Hessian). Finally, for problems with least squares functions (see “Statistics” subsection), as in data reconciliation, parameter estimation, and model predictive control, one can often assume that the values of the objective function and its gradient at the solution are vanishingly small. Under these conditions, one can show that the multipliers  $(\lambda, v)$  also vanish and  $\nabla_{xx} L(x, \lambda, v)$  can be substituted by  $\nabla_{xx} f(x^*)$ . This *Gauss-Newton approximation* has been shown to be very efficient for the solution of least squares problems [see Nocedal and Wright (1999)].

2. *Line search and trust region methods promote convergence from poor starting points.* These are commonly used with the search directions calculated from NLP subproblems such as (3-100). In a *trust region approach*, the constraint  $\|p\| \leq \Delta$  is added and the iteration step is taken if there is sufficient reduction of some merit function (e.g., the objective function weighted with some measure of the constraint violations). The size of the trust region  $\Delta$  is adjusted based on the agreement of the reduction of the actual merit function compared to its predicted reduction from the subproblem (see Conn et al., 2000, for details). Such methods have strong global convergence properties and are especially appropriate for ill-conditioned NLPs. This approach has been applied in the KNITRO code [Byrd, Hribar, and Nocedal, *SIAM J. Optimization* 9(4):877 (1999)]. *Line search methods* can be more efficient on problems with reasonably good starting points and well-conditioned subproblems, as in real-time optimization. Typically, once a search direction is calculated from (3-100), or other related subproblem, a step size  $\alpha \in (0, 1)$  is chosen so that  $x^k + \alpha p$  leads to a sufficient decrease of a merit function. As a recent alternative, a novel *filter* stabilization strategy (for both line search and trust region approaches) has been developed based on a bicriterion minimization, with the objective function and constraint infeasibility as competing objectives [Fletcher et al., *SIAM J. Optimization* 13(3):635 (2002)]. This method often leads to better performance than that based on merit functions.

3. *Regularization of the KKT matrix for the NLP subproblem is essential for good performance of general-purpose algorithms.* For instance, to obtain a unique solution to (3-100), active constraint gradients must be full rank and the Hessian matrix, when projected into the null space of the active constraint gradients, must be positive definite. These properties may not hold far from the solution, and corrections to the Hessian in SQP may be necessary (see Fletcher, 1987). Regularization methods ensure that subproblems such as (3-100) remain well-conditioned; they include addition of positive constants to the diagonal of the Hessian matrix to ensure its positive definiteness, judicious selection of active constraint gradients to ensure that they are linearly independent, and scaling the subproblem to reduce the propagation of numerical errors. Often these strategies are heuristics built into particular NLP codes. While quite effective, most of these heuristics do not provide convergence guarantees for general NLPs.

From the conceptual descriptions as well as algorithmic details given above, it is clear that NLP solvers are complex algorithms that have required considerable research and development to turn them into reliable and efficient software tools. Practitioners who are confronted with engineering optimization problems should therefore leverage these efforts, rather than write their own codes. Table 3-4 presents a sampling of available NLP codes that represent the above classifications. Much more information on these and other codes can be found on the NEOS server ([www-neos.mcs.anl.gov](http://www-neos.mcs.anl.gov)) and the NEOS Software Guide: <http://www-fp.mcs.anl.gov/otc/Guide/SoftwareGuide>.

TABLE 3-4 Representative NLP Solvers

| Method                     | Algorithm type                          | Stabilization | Second-order information |
|----------------------------|---|---------------|--------------------------|
| CONOPT<br>(Drud, 1994)     | Reduced gradient                        | Line search   | Exact and quasi-Newton   |
| GRC2 (Edgar et al., 2002)  | Reduced gradient                        | Line search   | Quasi-Newton             |
| IPOPT                      | SQP, barrier                            | Line search   | Exact                    |
| KNITRO (Byrd et al., 1997) | SQP, barrier                            | Trust region  | Exact and quasi-Newton   |
| LANCELOT                   | Augmented lagrangian, bound constrained | Trust region  | Exact and quasi-Newton   |
| LOQO                       | SQP, barrier                            | Line search   | Exact                    |
| MINOS                      | Reduced gradient, augmented lagrangian  | Line search   | Quasi-Newton             |
| NPSOL                      | SQP, active set                         | Line search   | Quasi-Newton             |
| SNOPT                      | Reduced space SQP, active set           | Line search   | Quasi-Newton             |
| SOCS                       | SQP, active set                         | Line search   | Exact                    |
| SOLVER                     | Reduced gradient                        | Line search   | Quasi-Newton             |
| SRQP                       | Reduced space SQP, active set           | Line search   | Quasi-Newton             |

### OPTIMIZATION METHODS WITHOUT DERIVATIVES

A broad class of optimization strategies does not require derivative information. These methods have the advantage of easy implementation and little prior knowledge of the optimization problem. In particular, such methods are well suited for "quick and dirty" optimization studies that explore the scope of optimization for new problems, prior to investing effort for more sophisticated modeling and solution strategies. Most of these methods are derived from heuristics that naturally spawn numerous variations. As a result, a very broad literature describes these methods. Here we discuss only a few important trends in this area.

**Classical Direct Search Methods** Developed in the 1960s and 1970s, these methods include one-at-a-time search and methods based on experimental designs (EVOP). At that time, these direct search methods were the most popular optimization methods in chemical engineering. Methods that fall into this class include the pattern search of Hooke and Jeeves [*J. ACM* **8**:212 (1961)], the conjugate direction method of Powell (1964), simplex and complex searches, in particular Nelder-Mead [*Comput. J.* **7**: 308 (1965)], and the adaptive random search methods of Luus-Jaakola [*AIChE J.* **19**: 760 (1973)], Goulcher and Cesares Long [*Comp. Chem. Engr.* **2**: 23 (1978)] and

Banga et al. [in *State of the Art in Global Optimization*, C. Floudas and P. Pardalos (eds.), Kluwer, Dordrecht, p. 563 (1996)]. All these methods require only objective function values for unconstrained minimization. Associated with these methods are numerous studies on a wide range of process problems. Moreover, many of these methods include heuristics that prevent premature termination (e.g., directional flexibility in the complex search as well as random restarts and direction generation). To illustrate these methods, Fig. 3-58 illustrates the performance of a pattern search method as well as a random search method on an unconstrained problem.

**Simulated Annealing** This strategy is related to random search methods and derives from a class of heuristics with analogies to the motion of molecules in the cooling and solidification of metals [Laarhoven and Aarts, *Simulated Annealing: Theory and Applications*, Reidel Publishing, Dordrecht (1987)]. Here a temperature parameter  $\theta$  can be raised or lowered to influence the probability of accepting points that do not improve the objective function. The method starts with a base point  $x$  and objective value  $f(x)$ . The next point  $x'$  is chosen at random from a distribution. If  $f(x') < f(x)$ , the move is accepted with  $x'$  as the new point. Otherwise,  $x'$  is accepted with probability  $p(\theta, x', x) = \exp\{-[f(x') - f(x)]/\theta\}$  and the Glauber distribution,  $p(\theta, x, x') = \exp\{-[f(x') - f(x)]/\theta\} / (1 + \exp\{-[f(x') - f(x)]/\theta\})$ . The  $\theta$  parameter is then reduced, and the method continues until no further progress is made.

**Genetic Algorithms** This approach, first proposed in Holland, J. H., *Adaptations in Natural and Artificial Systems* [University of Michigan Press, Ann Arbor (1975)], is based on the analogy of improving a population of solutions through modifying their gene pool. It also has similar performance characteristics as random search methods and simulated annealing. Two forms of genetic modification, crossover or mutation, are used and the elements of the optimization vector  $\mathbf{x}$  are represented as binary strings. Crossover deals with random swapping of vector elements (among parents with highest objective function values or other rankings of population) or any linear combinations of two parents. Mutation deals with the addition of a random variable to elements of the vector. Genetic algorithms (GAs) have seen widespread use in process engineering, and a number of codes are available. Edgar et al. (2002) describe a related GA that is available in MS Excel.

**Derivative-free Optimization (DFO)** In the past decade, the availability of parallel computers and faster computing hardware and the need to incorporate complex simulation models within optimization studies have led a number of optimization researchers to reconsider classical direct search approaches. In particular, Dennis and Torczon [*SIAM J. Optim.* **1**: 448 (1991)] developed a multidimensional search algorithm that extends the simplex approach of Nelder

FIG. 3-58 Examples of optimization methods without derivatives. (a) Pattern search method. (b) Random search method. ○, first phase; △, second phase; ◻, third phase.

and Mead (1965). They note that the Nelder-Mead algorithm fails as the number of variables increases, even for very simple problems. To overcome this, their multidimensional pattern search approach combines reflection, expansion, and contraction steps that act as line search algorithms for a number of linear independent search directions. This approach is easily adapted to parallel computation, and the method can be tailored to the number of processors available. Moreover, this approach converges to locally optimal solutions for unconstrained problems and observes an unexpected performance synergy when multiple processors are used. The work of Dennis and Torczon (1991) has spawned considerable research on the analysis and code development for DFO methods. For instance, Conn et al. [*Math. Programming*, Series B, **79**(3): 397 (1997)] constructed a multivariable DFO algorithm that uses a surrogate model for the objective function within a trust region method. Here points are sampled to obtain a well-defined quadratic interpolation model, and descent conditions from trust region methods enforce convergence properties. A number of trust region methods that rely on this approach are reviewed in Conn et al. (1997). Moreover, a number of DFO codes have been developed that lead to black box optimization implementations for large, complex simulation models [see Audet and Dennis, *SIAM J. Optim.* **13**: 889 (2003); Kolda et al., *SIAM Rev.* **45**(3): 385 (2003)]. These include the DAKOTA package at Sandia National Lab (Eldred, 2002; <http://endo.sandia.gov/DAKOTA/software.html>) and FOCUS developed at Boeing Corporation (Booker et al., CRPC Technical Report 98739, Rice University, February 1998).

Direct search methods are easy to apply to a wide variety of problem types and optimization models. Moreover, because their termination criteria are not based on gradient information and stationary points, they are more likely to favor the search for globally optimal rather than locally optimal solutions. These methods can also be adapted easily to include integer variables. However, no rigorous convergence properties to globally optimal solutions have yet been discovered. Also, these methods are best suited for unconstrained problems or for problems with simple bounds. Otherwise, they may have difficulties with constraints, as the only options open for handling constraints are equality constraint elimination and addition of penalty functions for inequality constraints. Both approaches can be unreliable and may lead to failure of the optimization algorithm. Finally, the performance of direct search methods scales poorly (and often exponentially) with the number of decision variables. While performance can be improved with the use of parallel computing, these methods are rarely applied to problems with more than a few dozen decision variables.

**GLOBAL OPTIMIZATION**

Deterministic optimization methods are available for nonconvex nonlinear programming problems of the form (3-85) that guarantee convergence to the global optimum. More specifically, one can show under mild conditions that they converge to an  $\epsilon$  distance to the global optimum in a finite number of steps. These methods are generally more expensive than local NLP methods, and they require the exploitation of the structure of the nonlinear program.

Because there are no optimality conditions like the KKT conditions for global optimization, these methods work by first partitioning the problem domain (i.e., containing the feasible region) into subregions. Upper bounds on the objective function are computed over all subregions of the problem. In addition, lower bounds can be derived from convex relaxations of the objective function and constraints for each subregion. The algorithm then proceeds to eliminate all subregions that have infeasible constraint relaxations or lower bounds that are greater than the least upper bound. After this, the remaining regions are further partitioned to create new subregions, and the cycle continues until the upper and lower bounds converge.

This basic concept leads to a wide variety of global algorithms, with the following features that can exploit different problem classes. *Bounding* strategies relate to the calculation of upper and lower bounds. For the former, any feasible point or, preferably, a locally optimal point in the subregion can be used. For the lower bound, convex relaxations of the objective and constraint functions are derived.

The *refining* step deals with the construction of partitions in the domain and further partitioning them during the search process. Finally, the *selection* step decides on the order of exploring the open subregions.

For simplicity, consider the problem  $\text{Min } f(x)$  subject to  $g(x) \leq 0$  where each function can be defined by additive terms. Convex relaxations for  $f(x)$  and  $g(x)$  can be derived in the following ways:

- Convex additive terms remain unmodified in these functions.
- Concave additive unary terms are replaced by a linear underestimating function that matches the term at the bounds of the subregion.
- Nonconvex polynomial terms can be replaced by a set of binary terms, with new variables introduced to define the higher-order polynomials.
- Binary terms can be relaxed by using the McCormick underestimator; e.g., the binary term  $xz$  is replaced by a new variable  $w$  and linear inequality constraints

$$\begin{aligned} w &\geq x_l z + z_l x - x_l z_l \\ w &\geq x_u z + z_u x - x_u z_u \\ w &\leq x_l z + z_l x - x_l z_l \\ w &\leq x_u z + z_u x - x_u z_u \end{aligned} \tag{3-107}$$

where the subregions are defined by  $x_l \leq x \leq x_u$  and  $z_l \leq z \leq z_u$ . Thus the feasible region and the objective function are replaced by convex envelopes to form relaxed problems.

Solving these convex relaxed problems leads to global solutions that are lower bounds to the NLP in the particular subregion. Finally, we see that gradient-based NLP solvers play an important role in global optimization algorithms, as they often yield the lower and upper bounds for the subregions. The *spatial branch and bound* global optimization algorithm can therefore be given by the following steps:

0. Initialize algorithm: calculate upper and lower bounds over the entire (relaxed) feasible region.
- For iteration  $k$  with a set of partitions  $M_{kj}$  and bounds in each subregion  $f_{lj}$  and  $f_{uj}$ :
  1. *Bound*. Define best upper bound:  $f_U = \min_j f_{Uj}$  and delete (fathom) all subregions  $j$  with lower bounds  $f_{lj} \geq f_U - \epsilon$ . If the remaining subregions satisfy  $f_{lj} \geq f_U - \epsilon$ , stop.
  2. *Refine*. Divide the remaining active subregions into partitions  $M_{k,j1}$  and  $M_{k,j2}$ . (Many branching rules are available for this step.)
  3. *Select*. Solve the convex relaxed NLP in the new partitions to obtain  $f_{l,j1}$  and  $f_{l,j2}$ . Delete the partition if there is no feasible solution.
  4. *Update*. Obtain upper bounds  $f_{Uj1}$  and  $f_{Uj2}$  to new partitions, if present. Set  $k = k+1$ , update partition sets, and go to step 1.

**Example** To illustrate the spatial branch and bound algorithm, consider the global solution of

$$\text{Min } f(x) = \frac{5}{2} x^4 - 20x^3 + 55x^2 - 57x, \quad \text{subject to } 0.5 \leq x \leq 2.5 \tag{3-108}$$

As seen in Fig. 3-59, this problem has local solutions at  $x^* = 2.5$  and at  $x^* = 0.8749$ . The latter is also the global solution with  $f(x^*) = -19.7$ . To find the global solution, we note that all but the  $-20x^3$  term in (3-108) are convex, so we replace this term by a new variable and a linear underestimator within a particular subregion, i.e.,

$$\begin{aligned} \text{Min } f_L(x) &= \frac{5}{2} x^4 - 20w + 55x^2 - 57x \\ \text{subject to } x_l &\leq x \leq x_u \\ w &= x_l^3 \frac{x_u - x}{x_u - x_l} + x_u^3 \frac{x - x_l}{x_u - x_l} \end{aligned} \tag{3-109}$$

In Fig. 3-59 we also propose subregions that are created by simple bisection partitioning rules, and we use a “loose” bounding tolerance of  $\epsilon = 0.2$ . In each partition the lower bound  $f_L$  is determined by (3-109) and the upper bound  $f_U$  is determined by the local solution of the original problem in the subregion. Figure 3-60 shows the progress of the spatial branch and bound algorithm as the partitions are refined and the bounds are updated. In Fig. 3-60, note the definitions of the partitions for the nodes, and the sequence numbers in each node that show the order in which the partitions are

FIG. 3-59 Global optimization example with partitions.

processed. The grayed partitions correspond to the deleted subregions, and at termination of the algorithm we see that  $f_L \geq f_U - \epsilon$  (that is,  $-19.85 \geq -19.7 - 0.2$ ), with the gray subregions in Fig. 3-59 still active. Further partitioning in these subregions will allow the lower and upper bounds to converge to a tighter tolerance.

Note that a number of improvements can be made to the bounding, refinement, and selection strategies in the algorithm that accelerate the convergence of this method. A comprehensive discussion of all these options can be found in Floudas (2000), Tawarlamani and Sahinidis (2002), and Horst and Tuy (1993). Also, a number of efficient global optimization codes have recently been developed, including  $\alpha$ BB, BARON, LGO, and OQNLP. An interesting numerical comparison of these and other codes can be found in Neumaier et al., *Math. Prog. B* 103(2): 335 (2005).

**MIXED INTEGER PROGRAMMING**

Mixed integer programming deals with both discrete and continuous decision variables. For the purpose of illustration we consider discrete decisions as binary variables, that is,  $y_i = 0$  or  $1$ , and we consider the mixed integer problem (3-84). Unlike in local optimization methods, there are no optimality conditions, such as the KKT conditions, that can be applied directly. Instead, as in the global optimization methods, a systematic search of the solution space, coupled with upper and lower bounding information, is applied. As with global optimization problems, large mixed integer programs can be expensive to solve, and some care is needed in the problem formulation.

**Mixed Integer Linear Programming** If the objective and constraint functions are all linear, then (3-84) becomes a mixed integer linear programming problem given by

$$\begin{aligned} \text{Min } Z &= a^T x + c^T y \\ \text{subject to } Ax + By &\leq b \\ x &\geq 0, y \in \{0, 1\}^l \end{aligned} \tag{3-110}$$

Note that if we relax the  $t$  binary variables by the inequalities  $0 \leq y \leq 1$ , then (3-110) becomes a linear program with a (global) solution that is a lower bound to the MILP (3-110). There are specific MILP classes where the LP relaxation of (3-110) has the same solution as the MILP. Among these problems is the well-known *assignment problem*. Other MILPs that can be solved with efficient special-purpose methods are the *knapsack problem*, the *set covering* and *set partitioning* problems, and the *traveling salesperson problem*. See Nemhauser and Wolsey (1988) for a detailed treatment of these problems.

More generally, MILPs are solved with branch and bound algorithms, similar to the spatial branch and bound method of the previous section, that explore the search space. As seen in Fig. 3-61, binary variables are used to define the search tree, and a number of bounding properties can be noted from the structure of (3-110).

Upper bounds on the objective function can be found from any feasible solution to (3-110), with  $y$  set to integer values. These can be found at the bottom or “leaf” nodes of a branch and bound tree (and sometimes at intermediate nodes as well). The top, or root, node in

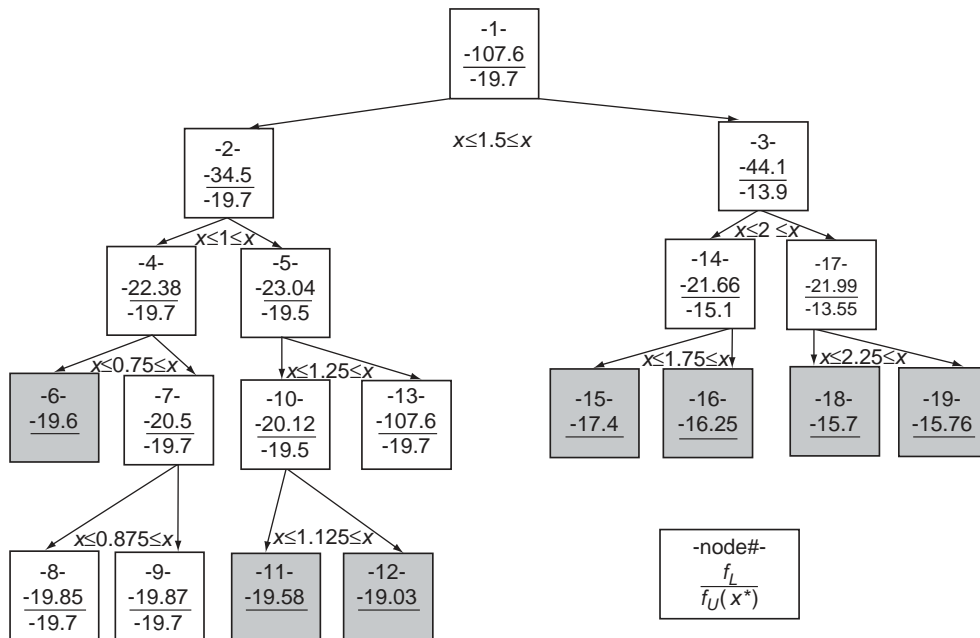

FIG. 3-60 Spatial branch and bound sequence for global optimization example.

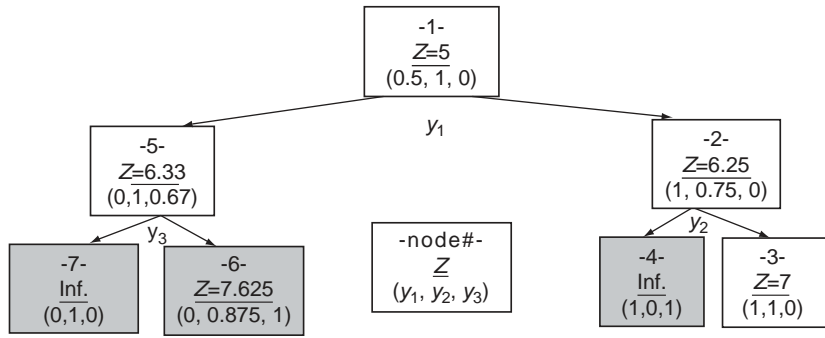

FIG. 3-61 Branch and bound sequence for MILP example.

the tree is the solution to the linear programming relaxation of (3-110); this is a lower bound to (3-110). On the other hand, as one proceeds down the tree with a partial assignment of the binary variables, a lower bound for any leaf node in that branch can be found from solution of the linear program at this intermediate node with the remaining binary variables relaxed. This leads to the following properties:

- Any intermediate node with an infeasible LP relaxation has infeasible leaf nodes and can be fathomed (i.e., all remaining children of this node can be eliminated).
- If the LP solution at an intermediate node is not less than an existing integer solution, then the node can be fathomed.

These properties lead to pruning of the search tree. Branching then continues in the tree until the upper and lower bounds converge.

This basic concept leads to a wide variety of MILP algorithms with the following features. LP solutions at intermediate nodes are relatively easy to calculate with the simplex method. If the solution of the parent node is known, multiplier information from this solution can be used to calculate (via a very efficient pivoting operation) the LP solution at the child node. Branching strategies to navigate the tree take a number of forms. More common *depth-first strategies* expand the most recent node to a leaf node or infeasible node and then backtrack to other branches in the tree. These strategies are simple to program and require little storage of past nodes. On the other hand, *breadth-first strategies* expand all the nodes at each level of the tree, select the node with the lowest objective function, and then proceed until the leaf nodes are reached. Here, more storage is required but generally fewer nodes are evaluated than in depth-first search. In addition, *selection of binary variable for branching* is based on a number of criteria, including choosing the variable with the relaxed value closest to 0 or 1, or the one leading to the largest change in the objective. Additional description of these strategies can be found in Biegler et al. (1997) and Nemhauser and Wolsey (1988).

**Example** To illustrate the branch and bound approach, we consider the MILP:

$$\begin{aligned} \text{Min } Z &= x + y_1 + 2y_2 + 3y_3 \\ \text{subject to } &-x + 3y_1 + y_2 + 2y_3 \leq 0 \\ &-4y_1 - 8y_2 - 3y_3 \leq -10 \\ &x \geq 0, y_1, y_2, y_3 = \{0, 1\} \end{aligned} \quad (3-111)$$

The solution to (3-111) is given by  $x = 4, y_1 = 1, y_2 = 1, y_3 = 0$ , and  $Z = 7$ . Here we use a depth-first strategy and branch on the variables closest to 0 or 1. Fig. 3-61 shows the progress of the branch and bound algorithm as the binary variables are selected and the bounds are updated. The sequence numbers for each node in Fig. 3-61 show the order in which they are processed. The grayed partitions correspond to the deleted nodes, and at termination of the algorithm we see that  $Z = 7$  and an integer solution is obtained at an intermediate node where coincidentally  $y_3 = 0$ .

A number of improvements that can be made to the branching rules will accelerate the convergence of this method. A comprehensive discussion of all these options can be found in Nemhauser and Wolsey (1988). Also, a number of efficient MILP codes have recently been developed, including CPLEX, OSL, XPRESS, and ZOOM. All these serve as excellent large-scale optimization codes as well. A detailed description and availability of these and other MILP solvers

can be found in the NEOS Software Guide: <http://www-fp.mcs.anl.gov/otc/Guide/SoftwareGuide>.

**Mixed Integer Nonlinear Programming** Without loss of generality, we can rewrite the MINLP in (3-84) as:

$$\begin{aligned} \text{Min } Z &= f(x) + c^T y \\ \text{subject to } &g(x) + By \leq b \\ &x \geq 0, y \in \{0, 1\}^l \end{aligned} \quad (3-112)$$

where the binary variables are kept as separate linear terms. We develop several MINLP solution strategies by drawing from the material in the preceding sections. MINLP strategies can be classified into two types. The first deals with nonlinear extensions of the branch and bound method discussed above for MILPs. The second deals with outer approximation decomposition strategies that provide lower and upper bounding information for convergence.

**Nonlinear Branch and Bound** The MINLP (3-112) can be solved in a similar manner to (3-110). If the functions  $f(x)$  and  $g(x)$  in (3-112) are convex, then direct extensions to the branch and bound method can be made. A relaxed NLP can be solved at the root node, upper bounds to the solution of (3-112) can be found at the leaf nodes, and the bounding properties due to NLP solutions at intermediate nodes still hold. However, this approach is more expensive than the corresponding MILP method. First, NLPs are more expensive than LPs to solve. Second, unlike with relaxed LP solutions, NLP solutions at child nodes cannot be updated directly from solutions at parent nodes. Instead, the NLP needs to be solved again (but one hopes with a better starting guess). The NLP branch and bound method is used in the SBB code interfaced to GAMS. In addition, Leyffer, [*Comput. Optim. Appl.* 18: 295 (2001)] proposed a hybrid MINLP strategy nested within an SQP algorithm. At each iteration, a mixed integer quadratic program is formed, and a branch and bound algorithm is executed to solve it.

If  $f(x)$  and  $g(x)$  are nonconvex, additional difficulties can occur. In this case, nonunique, local solutions can be obtained at intermediate nodes, and consequently lower bounding properties would be lost. In addition, the nonconvexity in  $g(x)$  can lead to locally infeasible problems at intermediate nodes, even if feasible solutions can be found in the corresponding leaf node. To overcome problems with nonconvexities, global solutions to relaxed NLPs can be solved at the intermediate nodes. This preserves the lower bounding information and allows nonlinear branch and bound to inherit the convergence properties from the linear case. However, as noted above, this leads to much more expensive solution strategies.

**Outer Approximation Decomposition Methods** Again, we consider the MINLP (3-112) with convex  $f(x)$  and  $g(x)$ . Note that the NLP with binary variables fixed at  $\bar{y}$

$$\begin{aligned} \text{Min } Z &= f(x) + c^T \bar{y} \\ \text{subject to } &g(x) + B\bar{y} \leq b \\ &x \geq 0 \end{aligned} \quad (3-113)$$

if feasible, leads to a solution that is an upper bound on the MINLP

solution. In addition, linearizations of convex functions lead to underestimation of the function itself:

$$\phi(x) \geq \phi(x^k) + \nabla\phi(x^k)^T(x - x^k) \quad (3-114)$$

Consequently, linearization of (3-112) at a point  $x^k$ , to form the problem

$$\begin{aligned} \text{Min } Z &= f(x^k) + \nabla f(x^k)^T(x - x^k) + c^T y \\ \text{subject to } &g(x^k) + \nabla g(x^k)^T(x - x^k) + B y \leq b \\ &x \geq 0, y \in \{0, 1\}^l \end{aligned} \quad (3-115)$$

leads to overapproximation of the feasible region and underapproximation of the objective function in (3-112). Consequently, solution of (3-115) is a lower bound to the solution of (3-112). Adding more linearizations from other points does not change the bounding property, so for a set of points  $x^l, l = 1, \dots, k$ , the problem

$$\begin{aligned} \text{Min } Z &= \alpha \\ \text{subject to } &\alpha \geq f(x^l) + \nabla f(x^l)^T(x - x^l) + c^T y \\ &g(x^l) + \nabla g(x^l)^T(x - x^l) + B y \leq b \\ &x \geq 0, y \in \{0, 1\}^l \end{aligned} \quad l = 1, \dots, k \quad (3-116)$$

where  $\alpha$  is a scalar variable, still has a solution that is a lower bound to (3-112). The outer approximation strategy is depicted in Fig. 3-62.

The outer approximation algorithm [Duran, M., and I. E. Grossmann, *Math. Programming* **36**: 307 (1986)] begins by initializing the problem, either with a predetermined starting guess or by solving a relaxed NLP based on (3-112). An upper bound to the solution is then generated by fixing the binary variables to their current values  $y^k$  and solving the NLP (3-113). This solution determines the continuous variable values  $x^k$  for the MILP (3-116). [If (3-113) is an infeasible problem, any point may be chosen for  $x^k$ , or the linearizations could be omitted.] Note that this MILP also contains linearizations from previous solutions of (3-113). Finally, the integer cut  $\sum |y_i - y_i^k| \geq 1$  is added to (3-116) to avoid revisiting previously encountered values of binary variables. (In convex problems the integer cut is not needed, but it helps to accelerate solution of the MILP.) Solution of (3-116) yields new values of  $y$  and (without the integer cut) must lead to a lower bound to the solution of (3-112). Consequently, if the objective function of the lower bounding MILP is greater than the least upper bound determined in solutions of (3-113), then the algorithm terminates. Otherwise, the new values of  $y$  are used to solve the next NLP (3-113).

Compared to nonlinear branch and bound, the outer approximation algorithm usually requires very few solutions of the MILP and NLP subproblems. This is especially advantageous on problems where the NLPs are large and expensive to solve. Moreover, there are two variations of outer approximation that may be suitable for particular problem types:

In *Generalized Benders Decomposition* (GBD) [see Sahinidis and Grossmann, *Computers and Chem. Eng.* **15**: 481 (1991)], the lower

bounding problem in Fig. 3-62 is replaced by the following MILP:

$$\begin{aligned} \text{Min } &\alpha \\ \text{subject to } &\alpha \geq f(x^l) + c^T y + v^{lT} [g(x^l) + B y] \\ &\sum |y_i - y_i^l| \geq 1 \end{aligned} \quad l = 1, \dots, k \quad (3-117)$$

where  $v^l$  is the vector of KKT multipliers from the solution of (3-113) at iteration  $l$ . This MILP can be derived through a reformulation of the MILP used in Fig. 3-62 with the *inactive constraints* from (3-113) dropped. Solution of (3-117) leads to a weaker lower bound than (3-116), and consequently, more solutions of the NLP and MILP subproblems are needed to converge to the solution. However, (3-117) contains only a single continuous variable and far fewer inequality constraints and is much less expensive to solve than (3-116). Thus, GBD is favored over outer approximation if (3-113) is relatively inexpensive to solve or solution of (3-116) is too expensive.

The *extended cutting plane* (ECP) algorithm [Westerlund and Pettersson, *Computers and Chem. Engng.* **19**: S131 (1995)] is complementary to GBD. While the lower bounding problem in Fig. 3-62 remains essentially the same, the continuous variables  $x^k$  are chosen from the MILP solution and the NLP (3-113) is replaced by a simple evaluation of the objective and constraint functions. As a result, only MILP problems [(3-116) plus integer cuts] need be solved. Consequently, the ECP approach has weaker upper bounds than outer approximation and requires more MILP solutions. It has advantages over outer approximation when the NLP (3-113) is expensive to solve.

Additional difficulties arise for the outer approximation algorithm and its GBD and ECP extensions when neither  $f(x)$  nor  $g(x)$  is convex. Under these circumstances, the lower bounding properties resulting from the linearization and formulation of the MILP subproblem are lost, and the MILP solution may actually exclude the solution of (3-112). Hence, these algorithms need to be applied with care to nonconvex problems. To deal with nonconvexities, one can relax the linearizations in (3-116) through the introduction of additional *deviation variables* that can be penalized in the objective function. Alternately, the linearizations in (3-116) can be replaced by valid underestimating functions, such as those derived for global optimization [e.g., (3-107)]. However, this requires knowledge of structural information for (3-112) and may lead to weak lower bounds in the resulting MILP.

Finally, the performance of both MILP and MINLP algorithms is strongly dependent on the problem formulations (3-110) and (3-112). In particular, the efficiency of the approach is impacted by the lower bounds produced by the relaxation of the binary variables and subsequent solution of the linear program in the branch and bound tree. A number of approaches have been proposed to improve the quality of the lower bounds, including these:

- Logic-based methods such as *generalized disjunctive programming* (GDP) can be used to formulate MINLPs with fewer discrete variables that have tighter relaxations. Moreover, the imposition of logic-based constraints prevents the generation of unsuitable alternatives, leading to a less expensive search. In addition, constrained logic programming (CLP) methods offer an efficient search alternative to MILP solvers for highly combinatorial problems. See Raman and Grossmann, *Computers and Chem. Engng.* **18**(7): 563 (1994) for more details.
- Convex hull formulations of MILPs and MINLPs lead to relaxed problems that have much tighter lower bounds. This leads to the examination of far fewer nodes in the branch and bound tree. See Grossmann and Lee, *Comput. Optim. Appl.* **26**: 83 (2003) for more details.
- *Reformulation and preprocessing* strategies including bound tightening of the variables, coefficient reduction, lifting facets, and special ordered set constraints frequently lead to improved lower bounds and significant performance improvements in mixed integer programming algorithms.

A number of efficient codes are available for the solution of MINLPs. These include the AlphaECP, BARON, DICOPT, MINLP, and SBB solvers; descriptions of these can be found on the <http://www.gamsworld.org/minlp/solvers.htm> web site.

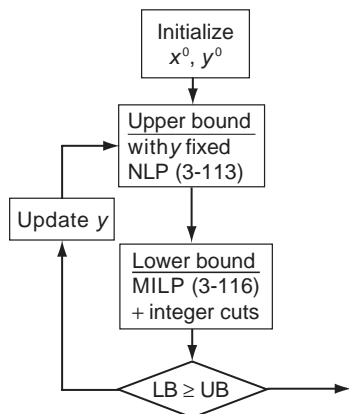

FIG. 3-62 Outer approximation MINLP algorithm.

## DEVELOPMENT OF OPTIMIZATION MODELS

The most important aspect to a successful optimization study is the formulation of the optimization model. These models must reflect the real-world problem so that meaningful optimization results are obtained; they also must satisfy the properties of the problem class. For instance, NLPs addressed by gradient-based methods need to have functions that are defined in the variable domain and have bounded and continuous first and second derivatives. In mixed integer problems, proper formulations are also needed to yield good lower bounds for efficient search. With increased understanding of optimization methods and the development of efficient and reliable optimization codes, optimization practitioners now focus on the *formulation* of optimization models that are realistic, well posed, and inexpensive to solve. Finally, convergence properties of NLP, MILP, and MINLP solvers require accurate first (and often second) derivatives from the optimization model. If these contain numerical errors (say, through finite difference approximations), then the performance of these solvers can deteriorate considerably. As a result of these characteristics, modeling platforms are essential for the formulation task. These are classified into two broad areas: optimization modeling platforms and simulation platforms with optimization.

*Optimization modeling platforms* provide general-purpose interfaces for optimization algorithms and remove the need for the user to interface to the solver directly. These platforms allow the general formulation for all problem classes discussed above with direct interfaces to state-of-the-art optimization codes. Three representative platforms are the GAMS (General Algebraic Modeling Systems), AMPL (A Mathematical Programming Language), and AIMMS (Advanced Integrated Multidimensional Modeling Software). All three require problem model input via a declarative modeling language and provide exact gradient and Hessian information through automatic differentiation strategies. Although it is possible, these platforms were not designed to handle externally added procedural models. As a result, these platforms are best applied on optimization models that can be developed entirely within their modeling framework. Nevertheless, these platforms are widely used for large-scale research and industrial applications. In addition, the MATLAB platform allows the flexible formulation of optimization models as well, although it currently has only limited capabilities for automatic differentiation and limited optimization solvers. More information on these and other modeling platforms can be found at <http://www-fp.mcs.anl.gov/otc/Guide/SoftwareGuide>.

*Simulation platforms with optimization* are often dedicated, application-specific modeling tools to which optimization solvers have been interfaced. These lead to very useful optimization studies, but because they were not originally designed for optimization models, they need to be used with some caution. In particular, most of these platforms do not provide exact derivatives to the optimization solver; often they are approximated through finite differences. In addition, the models themselves are constructed and calculated through numerical procedures, instead of through an open declarative language. Examples of these include widely used process simulators such as Aspen/Plus, PRO/II, and Hysys. Also note that more recent platforms such as Aspen Custom Modeler and gPROMS include declarative models and exact derivatives.

For optimization tools linked to procedural models, note that reliable and efficient automatic differentiation tools are available that link to models written, say, in FORTRAN and C, and calculate exact first (and often second) derivatives. Examples of these include ADIFOR, ADOL-C, GRESS, Odyssey, and PADRE. When used with care, these can be applied to existing procedural models and, when linked to modern NLP and MINLP algorithms, can lead to powerful optimization capabilities. More information on these and other automatic differentiation tools can be found at [http://www-unix.mcs.anl.gov/autodiff/AD\\_Tools/](http://www-unix.mcs.anl.gov/autodiff/AD_Tools/).

For optimization problems that are derived from (ordinary or partial) differential equation models, a number of advanced optimization strategies can be applied. Most of these problems are posed as NLPs, although recent work has also extended these models to MINLPs and global optimization formulations. For the optimization of profiles in time and space, *indirect methods* can be applied based on the optimality conditions of the infinite-dimensional problem using, for instance, the calculus of variations. However, these methods become difficult to apply if inequality constraints and discrete decisions are part of the optimization problem. Instead, current methods are based on NLP and MINLP formulations and can be divided into two classes:

- *Simultaneous formulations* are based on converting the differential equation model to algebraic constraints via discretization (say, with a Runge-Kutta method) and solving a large-scale NLP or MINLP. This approach requires efficient large-scale optimization solvers but also leads to very flexible and efficient problem formulations, particularly for optimal control and state-constrained problems. It also allows the treatment of unstable dynamics. A review of these strategies can be found in Biegler et al. [*Chem. Engng. Sci.* **57**(4): 575 (2002)] and Betts [*Practical Methods for Optimal Control Using Nonlinear Programming*, SIAM, Philadelphia (2001)].
- *Sequential formulations* require the linkage of NLP or MINLP solvers to embedded ODE or PDE solvers. This leads to smaller optimization problems only in the decision (or control) variables. However, an important aspect to this formulation is the need to recover accurate gradient information from the differential equation solver. Here, methods based on the solution of *direct* and *adjoint sensitivity* equations have been derived and automated [see Cao et al., *SIAM J. Sci. Comp.* **24**(3): 1076 (2003) for a description of these sensitivity methods]. For the former, commercial tools such as Aspen Custom Modeler and gPROMS have been developed.

Finally, the availability of automatic differentiation and related sensitivity tools for differential equation models allows for considerable flexibility in the formulation of optimization models. In van Bloemen Waanders et al. (Sandia Technical Report SAND2002-3198, October 2002), a seven-level modeling hierarchy is proposed that matches optimization algorithms with models that range from completely open (fully declarative model) to fully closed (entirely procedural without sensitivities). At the lowest, fully procedural level, only derivative-free optimization methods are applied, while the highest, declarative level allows the application of an efficient large-scale solver that uses first and second derivatives. This report notes that, based on the modeling level, optimization solver performance can vary by several orders of magnitude.

## STATISTICS

## INTRODUCTION

Statistics represents a body of knowledge which enables one to deal with quantitative data reflecting any degree of uncertainty. There are six basic aspects of applied statistics. These are:

1. Type of data
2. Random variables

3. Models
4. Parameters
5. Sample statistics
6. Characterization of chance occurrences

From these can be developed strategies and procedures for dealing with (1) estimation and (2) inferential statistics. The following has been directed more toward inferential statistics because of its broader utility.

Detailed illustrations and examples are used throughout to develop basic statistical methodology for dealing with a broad area of applications. However, in addition to this material, there are many specialized topics as well as some very subtle areas which have not been discussed. The references should be used for more detailed information. Section 8 discusses the use of statistics in statistical process control (SPC).

**Type of Data** In general, statistics deals with two types of data: counts and measurements. Counts represent the number of discrete outcomes, such as the number of defective parts in a shipment, the number of lost-time accidents, and so forth. Measurement data are treated as a continuum. For example, the tensile strength of a synthetic yarn theoretically could be measured to any degree of precision. A subtle aspect associated with count and measurement data is that some types of count data can be dealt with through the application of techniques which have been developed for measurement data alone. This ability is due to the fact that some simplified measurement statistics serve as an excellent approximation for the more tedious count statistics.

**Random Variables** Applied statistics deals with quantitative data. In tossing a fair coin the successive outcomes would tend to be different, with heads and tails occurring randomly over a period of time. Given a long strand of synthetic fiber, the tensile strength of successive samples would tend to vary significantly from sample to sample.

Counts and measurements are characterized as random variables, that is, observations which are susceptible to chance. Virtually all quantitative data are susceptible to chance in one way or another.

**Models** Part of the foundation of statistics consists of the mathematical models which characterize an experiment. The models themselves are mathematical ways of describing the probability, or relative likelihood, of observing specified values of random variables. For example, in tossing a coin once, a random variable  $x$  could be defined by assigning to  $x$  the value 1 for a head and 0 for a tail. Given a fair coin, the probability of observing a head on a toss would be a .5, and similarly for a tail. Therefore, the mathematical model governing this experiment can be written as

| $x$ | $P(x)$ |
|-----|--------|
| 0   | .5     |
| 1   | .5     |

where  $P(x)$  stands for what is called a probability function. This term is reserved for count data, in that probabilities can be defined for particular outcomes.

The probability function that has been displayed is a very special case of the more general case, which is called the binomial probability distribution.

For measurement data which are considered continuous, the term *probability density* is used. For example, consider a spinner wheel which conceptually can be thought of as being marked off on the circumference infinitely precisely from 0 up to, but not including, 1. In spinning the wheel, the probability of the wheel's stopping at a specified marking point at any particular  $x$  value, where  $0 \leq x < 1$ , is zero, for example, stopping at the value  $x = \sqrt{.5}$ . For the spinning wheel, the probability density function would be defined by  $f(x) = 1$  for  $0 \leq x < 1$ . Graphically, this is shown in Fig. 3-63. The relative-probability concept refers to the fact that density reflects the relative likelihood of occurrence; in this case, each number between 0 and 1 is equally likely. For measurement data, probability is defined by the area under the curve between specified limits. A density function always must have a total area of 1.

**Example** For the density of Fig. 3-63 the

$$P[0 \leq x \leq .4] = .4$$

FIG. 3-63 Density function.

$$P[.2 \leq x \leq .9] = .7$$

$$P[.6 \leq x < 1] = .4$$

and so forth. Since the probability associated with any particular point value is zero, it makes no difference whether the limit point is defined by a closed interval ( $\leq$  or  $\geq$ ) or an open interval ( $<$  or  $>$ ).

Many different types of models are used as the foundation for statistical analysis. These models are also referred to as **populations**.

**Parameters** As a way of characterizing probability functions and densities, certain types of quantities called parameters can be defined. For example, the center of gravity of the distribution is defined to be the population mean, which is designated as  $\mu$ . For the coin toss  $\mu = .5$ , which corresponds to the average value of  $x$ ; i.e., for half of the time  $x$  will take on a value 0 and for the other half a value 1. The average would be .5. For the spinning wheel, the average value would also be .5.

Another parameter is called the **standard deviation**, which is designated as  $\sigma$ . The square of the standard deviation is used frequently and is called the popular **variance**,  $\sigma^2$ . Basically, the standard deviation is a quantity which measures the spread or dispersion of the distribution from its mean  $\mu$ . If the spread is broad, then the standard deviation will be larger than if it were more constrained.

For specified probability and density functions, the respective means and variances are defined by the following:

| Probability functions                                | Probability density functions                           |
|--|---|
| $E(x) = \mu = \sum_x x P(x)$                         | $E(x) = \mu = \int_x x f(x) dx$                         |
| $\text{Var}(x) = \sigma^2 = \sum_x (x - \mu)^2 P(x)$ | $\text{Var}(x) = \sigma^2 = \int_x (x - \mu)^2 f(x) dx$ |

where  $E(x)$  is defined to be the expected or average value of  $x$ .

**Sample Statistics** Many types of sample statistics will be defined. Two very special types are the **sample mean**, designated as  $\bar{x}$ , and the sample standard deviation, designated as  $s$ . These are, by definition, random variables. Parameters like  $\mu$  and  $\sigma$  are not random variables; they are fixed constants.

**Example** In an experiment, six random numbers (rounded to four decimal places) were observed from the uniform distribution  $f(x) = 1$  for  $0 \leq x < 1$ :

- .1009
- .3754
- .0842
- .9901
- .1280
- .6606

The sample mean corresponds to the arithmetic average of the observations, which will be designated as  $x_1$  through  $x_6$ , where

$$\bar{x} = \frac{1}{n} \sum_{i=1}^n x_i \text{ with } n = 6, \quad \bar{x} = 0.3899$$

The sample standard deviation  $s$  is defined by the computation

$$s = \sqrt{\frac{\sum (x_i - \bar{x})^2}{n - 1}}$$

$$= \sqrt{\frac{n \sum x_i^2 - (\sum x_i)^2}{n(n-1)}} \quad (3-118)$$

In effect, this represents the root of a statistical average of the squares. The divisor quantity  $(n - 1)$  will be referred to as the degrees of freedom. The sample value of the standard deviation for the data given is .3686.

The value of  $n - 1$  is used in the denominator because the deviations from the sample average must total zero, or

$$\sum(x_i - \bar{x}) = 0$$

Thus knowing  $n - 1$  values of  $x_i - \bar{x}$  permits calculation of the  $n$ th value of  $x_i - \bar{x}$ .

The sample mean and sample standard deviation are obtained by using Microsoft Excel with the commands AVERAGE(B2:B7) and STDEV(B2:B7) when the observations are in cells B2 to B7.

In effect, the standard deviation quantifies the relative magnitude of the deviation numbers, i.e., a special type of “average” of the distance of points from their center. In statistical theory, it turns out that the corresponding variance quantities  $s^2$  have remarkable properties which make possible broad generalities for sample statistics and therefore also their counterparts, the standard deviations.

For the corresponding population, the parameter values are  $\mu = .50$  and  $\sigma = .2887$ , which are obtained by calculating the integrals defined above with  $f(x) = 1$  and  $0 \leq x \leq 1$ . If, instead of using individual observations only, averages of six were reported, then the corresponding population parameter values would be  $\mu = .50$  and  $\sigma_{\bar{x}} = \sigma/\sqrt{6} = .1179$ . The corresponding variance for an average will be written occasionally as  $\text{Var}(\bar{x}) = \text{var}(x)/n$ . In effect, the variance of an average is inversely proportional to the sample size  $n$ , which reflects the fact that sample averages will tend to cluster about  $\mu$  much more closely than individual observations. This is illustrated in greater detail under “Measurement Data and Sampling Densities.”

**Characterization of Chance Occurrences** To deal with a broad area of statistical applications, it is necessary to characterize the way in which random variables will vary by chance alone. The basic foundation for this characteristic is laid through a density called the gaussian, or normal, distribution.

Determining the area under the normal curve is a very tedious procedure. However, by standardizing a random variable that is normally distributed, it is possible to relate all normally distributed random variables to one table. The standardization is defined by the identity  $z = (x - \mu)/\sigma$ , where  $z$  is called the unit normal. Further, it is possible to standardize the sampling distribution of averages  $\bar{x}$  by the identity  $z = (\bar{x} - \mu)/(\sigma/\sqrt{n})$ .

A remarkable property of the normal distribution is that, almost regardless of the distribution of  $x$ , sample averages  $\bar{x}$  will approach the gaussian distribution as  $n$  gets large. Even for relatively small values of  $n$ , of about 10, the approximation in most cases is quite close. For example, sample averages of size 10 from the uniform distribution will have essentially a gaussian distribution.

Also, in many applications involving count data, the normal distribution can be used as a close approximation. In particular, the approximation is quite close for the binomial distribution within certain guidelines.

The normal probability distribution function can be obtained in Microsoft Excel by using the NORMDIST function and supplying the desired mean and standard deviation. The cumulative value can also be determined. In MATLAB, the corresponding command is randn.

### ENUMERATION DATA AND PROBABILITY DISTRIBUTIONS

**Introduction** Many types of statistical applications are characterized by enumeration data in the form of counts. Examples are the number of lost-time accidents in a plant, the number of defective items in a sample, and the number of items in a sample that fall within several specified categories.

The sampling distribution of count data can be characterized through probability distributions. In many cases, count data are appropriately

interpreted through their corresponding distributions. However, in other situations analysis is greatly facilitated through distributions which have been developed for measurement data. Examples of each will be illustrated in the following subsections.

#### Binomial Probability Distribution

**Nature** Consider an experiment in which each outcome is classified into one of two categories, one of which will be defined as a success and the other as a failure. Given that the probability of success  $p$  is constant from trial to trial, then the probability of observing a specified number of successes  $x$  in  $n$  trials is defined by the binomial distribution. The sequence of outcomes is called a **Bernoulli process**,

**Nomenclature**

$n$  = total number of trials

$x$  = number of successes in  $n$  trials

$p$  = probability of observing a success on any one trial

$\hat{p} = x/n$ , the proportion of successes in  $n$  trials

**Probability Law**

$$P(x) = P\left(\frac{x}{n}\right) = \binom{n}{x} p^x (1-p)^{n-x} \quad x = 0, 1, 2, \dots, n$$

where  $\binom{n}{x} = \frac{n!}{x!(n-x)!}$

**Properties**

$E(x) = np$        $\text{Var}(x) = np(1-p)$

$E(\hat{p}) = p$        $\text{Var}(\hat{p}) = p(1-p)/n$

#### Geometric Probability Distribution

**Nature** Consider an experiment in which each outcome is classified into one of two categories, one of which will be defined as a success and the other as a failure. Given that the probability of success  $p$  is constant from trial to trial, then the probability of observing the first success on the  $x$ th trial is defined by the geometric distribution.

**Nomenclature**

$p$  = probability of observing a success on any one trial

$x$  = the number of trials to obtain the first success

**Probability Law**

$$P(x) = p(1-p)^{x-1} \quad x = 1, 2, 3, \dots$$

**Properties**

$E(x) = 1/p$        $\text{Var}(x) = (1-p)/p^2$

#### Poisson Probability Distribution

**Nature** In monitoring a moving threadline, one criterion of quality would be the frequency of broken filaments. These can be identified as they occur through the threadline by a broken-filament detector mounted adjacent to the threadline. In this context, the random occurrences of broken filaments can be modeled by the Poisson distribution. This is called a Poisson process and corresponds to a probabilistic description of the frequency of defects or, in general, what are called arrivals at points on a continuous line or in time. Other examples include:

1. The number of cars (arrivals) that pass a point on a high-speed highway between 10:00 and 11:00 A.M. on Wednesdays
2. The number of customers arriving at a bank between 10:00 and 10:10 A.M.
3. The number of telephone calls received through a switchboard between 9:00 and 10:00 A.M.
4. The number of insurance claims that are filed each week
5. The number of spinning machines that break down during 1 day at a large plant.

**Nomenclature**

$x$  = total number of arrivals in a total length  $L$  or total period  $T$

$a$  = average rate of arrivals for a unit length or unit time

$\lambda = aL$  = expected or average number of arrivals for the total length  $L$

$\lambda = aT$  = expected or average number of arrivals for the total time  $T$

**Probability Law** Given that  $a$  is constant for the total length  $L$  or period  $T$ , the probability of observing  $x$  arrivals in some period  $L$  or  $T$

is given by

$$P(x) = \frac{\lambda^x}{x!} e^{-\lambda} \quad x = 0, 1, 2, \dots$$

**Properties**  $E(x) = \lambda \quad \text{Var}(x) = \lambda$

**Example** The number of broken filaments in a threadline has been averaging .015 per yard. What is the probability of observing exactly two broken filaments in the next 100 yd? In this example,  $a = .015/\text{yd}$  and  $L = 100$  yd; therefore  $\lambda = (.015)(100) = 1.5$ :

$$P(x = 2) = \frac{(1.5)^2}{2!} e^{-1.5} = .2510$$

**Example** A commercial item is sold in a retail outlet as a unit product. In the past, sales have averaged 10 units per month with no seasonal variation. The retail outlet must order replacement items 2 months in advance. If the outlet starts the next 2-month period with 25 items on hand, what is the probability that it will stock out before the end of the second month?

Given  $a = 10/\text{month}$ , then  $\lambda = 10 \times 2 = 20$  for the total period of 2 months:

$$P(x \geq 26) = \sum_{x=26}^{\infty} P(x) = 1 - \sum_{x=0}^{25} P(x)$$

$$\sum_{x=0}^{25} \frac{20^x}{x!} e^{-20} = e^{-20} \left[ 1 + \frac{20}{1} + \frac{20^2}{2!} + \dots + \frac{20^{25}}{25!} \right]$$

$$= .887815$$

Therefore  $P(x \geq 26) = .112185$  or roughly an 11 percent chance of a stockout.

### Hypergeometric Probability Distribution

**Nature** In an experiment in which one samples from a relatively small group of items, each of which is classified in one of two categories, A or B, the hypergeometric distribution can be defined. One example is the probability of drawing two red and two black cards from a deck of cards. The hypergeometric distribution is the analog of the binomial distribution when successive trials are not independent, i.e., when the total group of items is not infinite. This happens when the drawn items are not replaced.

**Nomenclature**

- $N$  = total group size
- $n$  = sample group size
- $X$  = number of items in the total group with a specified attribute A
- $N - X$  = number of items in the total group with the other attribute B
- $x$  = number of items in the sample with a specified attribute A
- $n - x$  = number of items in the sample with the other attribute B

|            | Population | Sample  |
|------------|------------|---------|
| Category A | $X$        | $x$     |
| Category B | $N - X$    | $n - x$ |
| Total      | $N$        | $n$     |

**Probability Law**

$$P(x) = \frac{\binom{N-X}{n-x} \binom{X}{x}}{\binom{N}{n}}$$

$$E(x) = \frac{nX}{N}$$

$$\text{var}(x) = nP(1-P) \frac{N-n}{N-1}$$

**Example** What is the probability that an appointed special committee of 4 has no female members when the members are randomly selected from a candidate group of 10 males and 7 females?

$$P(x = 0) = \frac{\binom{10}{4} \binom{7}{0}}{\binom{17}{4}} = .0882$$

**Example** A bin contains 300 items, of which 240 are good and 60 are defective. In a sample of 6 what is the probability of selecting 4 good and 2 defective items by chance?

$$P(x) = \frac{\binom{240}{4} \binom{60}{2}}{\binom{300}{6}} = .2478$$

### Multinomial Distribution

**Nature** For an experiment in which successive outcomes can be classified into two or more categories and the probabilities associated with the respective outcomes remain constant, then the experiment can be characterized through the multinomial distribution.

**Nomenclature**

- $n$  = total number of trials
- $k$  = total number of distinct categories
- $p_j$  = probability of observing category  $j$  on any one trial,  $j = 1, 2, \dots, k$
- $x_j$  = total number of occurrences in category  $j$  in  $n$  trials

**Probability Law**

$$P(x_1, x_2, \dots, x_k) = \frac{n!}{x_1!x_2! \dots x_k!} p_1^{x_1} p_2^{x_2} \dots p_k^{x_k}$$

**Example** In tossing a die 12 times, what is the probability that each face value will occur exactly twice?

$$p(2, 2, 2, 2, 2, 2) = \frac{12!}{2!2!2!2!2!2!} \left(\frac{1}{6}\right)^2 \left(\frac{1}{6}\right)^2 \left(\frac{1}{6}\right)^2 \left(\frac{1}{6}\right)^2 \left(\frac{1}{6}\right)^2 \left(\frac{1}{6}\right)^2 = .003438$$

To compute these probabilities in Microsoft Excel, put the value of  $x$  in cell B2, say, and use the functions

- Binomial distribution: = BINOMDIST(B2,  $n$ ,  $p$ , 0)
- Poisson distribution: = POISSON(B2,  $\lambda$ , 0)
- Hypergeometric distribution: = HYPGEOMDIST(B2,  $n$ ,  $X$ ,  $N$ )

To generate a table of values with these probability distributions, in Microsoft Excel use the following functions:

- Bernoulli random values: = CRITBINOM(1,  $p$ , RAND())
- Binomial random values: = CRITBINOM( $n$ ,  $p$ , RAND())

The factorial function is FACT( $n$ ) in Microsoft Excel and factorial( $n$ ) in MATLAB. Be sure that  $x$  is an integer.

### MEASUREMENT DATA AND SAMPLING DENSITIES

**Introduction** The following example data are used throughout this subsection to illustrate concepts. Consider, for the purpose of illustration, that five synthetic-yarn samples have been selected randomly from a production line and tested for tensile strength on each of 20 production days. For this, assume that each group of five corresponds to a day, Monday through Friday, for a period of 4 weeks:

| Monday<br>1       | Tuesday<br>2 | Wednesday<br>3 | Thursday<br>4 | Friday<br>5 | Groups of 25<br>pooled |
|-------------------|--------------|----------------|---------------|-------------|------------------------|
| 36.48             | 38.06        | 35.28          | 36.34         | 36.73       |                        |
| 35.33             | 31.86        | 36.58          | 36.25         | 37.17       |                        |
| 35.92             | 33.81        | 38.81          | 30.46         | 33.07       |                        |
| 32.28             | 30.30        | 33.31          | 37.37         | 34.27       |                        |
| 31.61             | 35.27        | 33.88          | 37.52         | 36.94       |                        |
| $\bar{x} = 34.32$ | 33.86        | 35.57          | 35.59         | 35.64       | 35.00                  |
| $s = 2.22$        | 3.01         | 2.22           | 2.92          | 1.85        | 2.40                   |
| 6                 | 7            | 8              | 9             | 10          |                        |
| 38.67             | 36.62        | 35.03          | 35.80         | 36.82       |                        |
| 32.08             | 33.05        | 36.22          | 33.16         | 36.49       |                        |
| 33.79             | 35.43        | 32.71          | 35.19         | 32.83       |                        |
| 32.85             | 36.63        | 32.52          | 32.91         | 32.43       |                        |
| 35.22             | 31.46        | 27.23          | 35.44         | 34.16       |                        |
| $\bar{x} = 34.52$ | 34.64        | 32.74          | 34.50         | 34.54       | 34.19                  |
| $s = 2.60$        | 2.30         | 3.46           | 1.36          | 2.03        | 2.35                   |

|                   |               |                 |                |              |                        |
|-------------------|---------------|-----------------|----------------|--------------|------------------------|
| 11                | 12            | 13              | 14             | 15           |                        |
| 39.63             | 34.52         | 36.05           | 36.64          | 31.57        |                        |
| 34.38             | 37.39         | 35.36           | 31.18          | 36.21        |                        |
| 36.51             | 34.16         | 35.00           | 36.13          | 33.84        |                        |
| 30.00             | 35.76         | 33.61           | 37.51          | 35.01        |                        |
| 39.64             | 37.63         | 36.98           | 39.05          | 34.95        |                        |
| $\bar{x} = 36.03$ | 35.89         | 35.40           | 36.10          | 34.32        | 35.55                  |
| $s = 4.04$        | 1.59          | 1.25            | 2.96           | 1.75         | 2.42                   |
| Monday<br>16      | Tuesday<br>17 | Wednesday<br>18 | Thursday<br>19 | Friday<br>20 | Groups of 25<br>pooled |
| 37.68             | 35.97         | 33.71           | 35.61          | 36.65        |                        |

| $s = 2.38$        | 1.02          | 1.90            | 2.25           | 3.27         | 2.52                   |

Pooled sample of 100:  $\bar{x} = 35.16$   $s = 2.47$

Even if the process were at steady state, tensile strength, a key property would still reflect some variation. Steady state, or stable operation of any process, has associated with it a characteristic variation. Superimposed on this is the testing method, which is itself a process with its own characteristic variation. The observed variation is a composite of these two variations.

Assume that the table represents "typical" production-line performance. The numbers themselves have been generated on a computer and represent random observations from a population with  $\mu = 35$  and a population standard deviation  $\sigma = 2.45$ . The sample values reflect the way in which tensile strength can vary by chance alone. In practice, a production supervisor unschooled in statistics but interested in high tensile performance would be despondent on the eighth day and exuberant on the twentieth day. If the supervisor were more concerned with uniformity, the lowest and highest points would have been on the eleventh and seventeenth days.

An objective of statistical analysis is to serve as a guide in decision making in the context of normal variation. In the case of the production supervisor, it is to make a decision, with a high probability of being correct, that something has in fact changed the operation.

Suppose that an engineering change has been made in the process and five new tensile samples have been tested with the results:

|       |                   |
|-------|-------------------|
| 36.81 |                   |
| 38.34 | $\bar{x} = 37.14$ |
| 34.87 | $s = 1.85$        |
| 39.58 |                   |
| 36.12 |                   |

In this situation, management would inquire whether the product has been improved by increased tensile strength. To answer this question, in addition to a variety of analogous questions, it is necessary to have some type of scientific basis upon which to draw a conclusion.

A scientific basis for the evaluation and interpretation of data is contained in the accompanying table descriptions. These tables characterize the way in which sample values will vary by chance alone in the context of individual observations, averages, and variances.

| Table number | Designated symbol | Variable                                | Sampling distribution of                   |
|--------------|-------------------|---|--|
| 3-5          | $z$               | $\frac{x - \mu}{\sigma}$                | Observations*                              |
| 3-5          | $z$               | $\frac{\bar{x} - \mu}{\sigma/\sqrt{n}}$ | Averages                                   |
| 3-6          | $t$               | $\frac{\bar{x} - \mu}{s/\sqrt{n}}$      | Averages when $\sigma$ is unknown*         |
| 3-7          | $\chi^2$          | $(s^2/\sigma^2)(df)$                    | Variances*                                 |
| 3-8          | $F$               | $s_1^2/s_2^2$                           | Ratio of two independent sample variances* |

\*When sampling from a gaussian distribution.

**Normal Distribution of Observations** Many types of data follow what is called the gaussian, or bell-shaped, curve; this is especially true of averages. Basically, the gaussian curve is a purely mathematical function which has very special properties. However, owing to some mathematically intractable aspects primary use of the function is restricted to tabulated values.

Basically, the tabled values represent area (proportions or probability) associated with a scaling variable designated by  $Z$  in Fig. 3-64. The normal curve is centered at 0, and for particular values of  $Z$ , designated as  $z$ , the tabulated numbers represent the corresponding area under the curve between 0 and  $z$ . For example, between 0 and 1 the area is .3413. (Get this number from Table 3-5. The value of  $A$  includes the area on both sides of zero. Thus we want  $A/2$ . For  $z = 1$ ,  $A = 0.6827$ ,  $A/2 = 0.3413$ . For  $z = 2$ ,  $A/2 = 0.4772$ .) The area between 0 and 2 is .4772; therefore, the area between 1 and 2 is  $.4772 - .3413 = .1359$ .

Also, since the normal curve is symmetric, areas to the left can be determined in exactly the same way. For example, the area between  $-2$  and  $+1$  would include the area between  $-2$  and 0,  $.4772$  (the same as 0 to 2), plus the area between 0 and 1,  $.3413$ , or a total area of  $.8185$ .

Any types of observation which are applicable to the normal curve can be transformed to  $Z$  values by the relationship  $z = (x - \mu)/\sigma$  and, conversely,  $Z$  values to  $x$  values by  $x = \mu + \sigma z$ , as shown in Fig. 3-64. For example, for tensile strength, with  $\mu = 35$  and  $\sigma = 2.45$ , this would dictate  $z = (x - 35)/2.45$  and  $x = 35 + 2.45z$ .

**Example** What proportion of tensile values will fall between 34 and 36?

$$z_1 = (34 - 35)/2.45 = -.41 \quad z_2 = (36 - 35)/2.45 = .41$$

$$P[-.41 \leq z \leq .41] = .3182, \text{ or roughly } 32 \text{ percent}$$

The value 0.3182 is interpolated from Table 3-4 using  $z = \pm 0.40$ ,  $A = 0.3108$ , and  $z = \pm 0.45$ ,  $A = 0.3473$ .

**Example** What midrange of tensile values will include 95 percent of the sample values? Since  $P[-1.96 \leq z \leq 1.96] = .95$ , the corresponding values of  $x$  are

$$x_1 = 35 - 1.96(2.45) = 30.2$$

$$x_2 = 35 + 1.96(2.45) = 39.8$$

or

$$P[30.2 \leq x \leq 39.8] = .95$$

**Normal Distribution of Averages** An examination of the tensile-strength data previously tabulated would show that the range (largest minus the smallest) of tensile strength within days averages 5.12. The average range in  $\bar{x}$  values within each week is 2.37, while the range in the four weekly averages is 1.72. This reflects the fact that averages tend to be less variable in a predictable way. Given that the variance of  $x$  is  $\text{var}(x) = \sigma^2$ , then the variance of  $\bar{x}$  based on  $n$  observations is  $\text{var}(\bar{x}) = \sigma^2/n$ .

For averages of  $n$  observations, the corresponding relationship for the  $Z$ -scale relationship is

$$z = (\bar{x} - \mu) / \sigma / \sqrt{n} \quad \text{or} \quad \bar{x} = \mu + \frac{\sigma}{\sqrt{n}} z$$

The Microsoft Excel function NORMDIST( $X, \mu, \sigma, 1$ ) gives the probability that  $x \leq \mu$ .

The command CONFIDENCE( $\alpha, \sigma, n$ ) gives the confidence interval about the mean for a sample size  $n$ . To obtain 95 percent confidence limits, use  $\alpha = .025$ ;  $2\alpha = 1 - A$ .

FIG. 3-64 Transformation of  $z$  values.

**TABLE 3-5 Ordinates and Areas between Abscissa Values  $-z$  and  $+z$  of the Normal Distribution Curve**

A = area between  $\mu - \sigma_z$  and  $\mu + \sigma_z$

| $z$         | $X$                   | $Y$    | $A$    | $1 - A$ | $z$         | $X$                   | $Y$     | $A$      | $1 - A$  |
|-------------|-----------------------|--------|--------|---------|-------------|-----------------------|---------|----------|----------|

| $\pm .385$  | $\mu \pm .385\sigma$  | .3704  | .3000  | .7000   | $\pm 1.960$ | $\mu \pm 1.960\sigma$ | .0584   | .9500    | .0500    |
| $\pm .524$  | $\mu \pm .524\sigma$  | .3477  | .4000  | .6000   | $\pm 2.576$ | $\mu \pm 2.576\sigma$ | .0145   | .9900    | .0100    |
| $\pm .674$  | $\mu \pm .674\sigma$  | .3178  | .5000  | .5000   | $\pm 3.291$ | $\mu \pm 3.291\sigma$ | .0018   | .9990    | .0010    |
| $\pm .842$  | $\mu \pm .842\sigma$  | .2800  | .6000  | .4000   | $\pm 3.891$ | $\mu \pm 3.891\sigma$ | .0002   | .9999    | .0001    |

This table is obtained in Microsoft Excel with the function  $Y = \text{NORMDIST}(X, \mu, \sigma, 0)$ .  
 If  $X > \mu$ ,  $A = 2 \text{ NORMDIST}(X, \mu, \sigma, 1) - 1$ . If  $X < \mu$ ,  $A = 1 - 2 \text{ NORMDIST}(X, \mu, \sigma, 1)$

**Example** What proportion of daily tensile averages will fall between 34 and 36? Using Table 3-5

$$z_1 = (34 - 35)/(2.45/\sqrt{5}) = -.91 \quad z_2 = (36 - 35)/(2.45/\sqrt{5}) = .91$$

$$P[-.91 \leq z \leq .91] = .637, \text{ or roughly } 64 \text{ percent}$$

Using Microsoft Excel, the more precise answer is

$$P[34 \leq \bar{x} \leq 36] = 2 \text{ NORMDIST}(36, 35, 2.45/\sqrt{5}, 1) - 1$$

$$= 1 - 2 \text{ NORMDIST}(34, 35, 2.45/\sqrt{5}, 1) = .6386$$

**Example** What midrange of daily tensile averages will include 95 percent of the sample values? Using Table 3-5

$$x_1 = 35 - 1.96(2.45/\sqrt{5}) = 32.85$$

$$x_2 = 35 + 1.96(2.45/\sqrt{5}) = 37.15$$

$$P[32.85 \leq \bar{x} \leq 37.15] = .95$$

or using Microsoft Excel,

$$35 \pm \text{CONFIDENCE}(.05, 2.45, 5) = 35 \pm 2.15$$

**t Distribution of Averages** The normal curve relies on a knowledge of  $\sigma$ , or in special cases, when it is unknown,  $s$  can be used with the normal curve as an approximation when  $n > 30$ . For example, with  $n > 30$  the intervals  $\bar{x} \pm s$  and  $\bar{x} \pm 2s$  will include roughly 68 and 95 percent of the sample values respectively when the distribution is normal.

In applications sample sizes are usually small and  $\sigma$  unknown. In these cases, the  $t$  distribution can be used where

$$t = (\bar{x} - \mu)/(s/\sqrt{n}) \quad \text{or} \quad \bar{x} = \mu + ts/\sqrt{n}$$

The  $t$  distribution is also symmetric and centered at zero. It is said to be robust in the sense that even when the individual observations  $x$  are not normally distributed, sample averages of  $x$  have distributions which tend toward normality as  $n$  gets large. Even for small  $n$  of 5

through 10, the approximation is usually relatively accurate. It is sometimes called the Student's  $t$  distribution.

In reference to the tensile-strength table, consider the summary statistics  $\bar{x}$  and  $s$  by days. For each day, the  $t$  statistic could be computed. If this were repeated over an extensive simulation and the resultant  $t$  quantities plotted in a frequency distribution, they would match the corresponding distribution of  $t$  values summarized in Table 3-6.

Since the  $t$  distribution relies on the sample standard deviation  $s$ , the resultant distribution will differ according to the sample size  $n$ . To designate this difference, the respective distributions are classified according to what are called the degrees of freedom and abbreviated as  $df$ . In simple problems, the  $df$  are just the sample size minus 1. In more complicated applications the  $df$  can be different. In general, degrees of freedom are the number of quantities minus the number of constraints. For example, four numbers in a square which must have row and column sums equal to zero have only one  $df$ , i.e., four numbers minus three constraints (the fourth constraint is redundant). The Microsoft Excel function  $\text{TDIST}(X, df, 1)$  gives the right-tail probability, and  $\text{TDIST}(X, df, 2)$  gives twice that. The probability that  $t \leq X$  is  $1 - \text{TDIST}(X, df, 1)$  when  $X \geq 0$  and  $\text{TDIST}(\text{abs}(X), df, 1)$  when  $X < 0$ . The probability that  $-X \leq t \leq +X$  is  $1 - 2\text{TDIST}(X, df, 2)$ .

**Example** For a sample size  $n = 5$ , what values of  $t$  define a midarea of 90 percent? For 4  $df$  the tabled value of  $t$  corresponding to a midarea of 90 percent is 2.132; i.e.,  $P[-2.132 \leq t \leq 2.132] = .90$ .

Using Microsoft Excel,  $\text{TINV}(.1, 4) = 2.132$ .

**Example** For a sample size  $n = 25$ , what values of  $t$  define a midarea of 95 percent? For 24  $df$  the tabled value of  $t$  corresponding to a midarea of 95 percent is 2.064; i.e.,  $P[-2.064 \leq t \leq 2.064] = .95$ .

**Example** Also,  $1 - \text{TDIST}(2.064, 24, 2) = .9500$ .

Using Microsoft Excel,  $\text{TINV}(.05, 24) = 2.064$ .

TABLE 3-6 Values of *t*

| ∞   | .253                    | .524                    | .842                    | 1.282                   | 1.645                   | 1.960                    | 2.326                   | 2.576                    |

Above values refer to a single tail outside the indicated limit of *t*. For example, for 95 percent of the area to be between  $-t$  and  $+t$  in a two-tailed *t* distribution, use the values for *t*<sub>.025</sub> or 2.5 percent for each tail. This table is obtained in Microsoft Excel using the function TINV( $\alpha$ ,df), where  $\alpha$  is .05.

**Example** What is the sample value of *t* for the first day of tensile data?  
 Sample  $t = (34.32 - 35)/(2.22/\sqrt{5}) = -6.8$

Note that on the average 90 percent of all such sample values would be expected to fall within the interval  $\pm 2.132$ .

***t* Distribution for the Difference in Two Sample Means with Equal Variances** The *t* distribution can be readily extended to the difference in two sample means when the respective populations have the same variance  $\sigma$ :

$$t = \frac{(\bar{x}_1 - \bar{x}_2) - (\mu_1 - \mu_2)}{s_p \sqrt{1/n_1 + 1/n_2}} \tag{3-119}$$

where  $s_p^2$  is a pooled variance defined by

$$s_p^2 = \frac{(n_1 - 1)s_1^2 + (n_2 - 1)s_2^2}{(n_1 - 1) + (n_2 - 1)} \tag{3-120}$$

In this application, the *t* distribution has  $(n_1 + n_2 - 2)$  df.

***t* Distribution for the Difference in Two Sample Means with Unequal Variances** When population variances are unequal, an approximate *t* quantity can be used:

$$t = \frac{(\bar{x}_1 - \bar{x}_2) - (\mu_1 - \mu_2)}{\sqrt{a + b}}$$

with  $a = s_1^2/n_1$        $b = s_2^2/n_2$

and 
$$df = \frac{(a + b)^2}{a^2/(n_1 - 1) + b^2/(n_2 - 1)}$$

**Chi-Square Distribution** For some industrial applications, product uniformity is of primary importance. The sample standard deviation *s* is most often used to characterize uniformity. In dealing with this problem, the chi-square distribution can be used where  $\chi^2 = (s^2/\sigma^2)(df)$ . The chi-square distribution is a family of distributions which are defined by the degrees of freedom associated with the sample variance. For most applications, df is equal to the sample size minus 1.

The probability distribution function is

$$p(y) = y_0 y^{df-2} \exp \left[ \frac{-(df)y^2}{2} \right]$$

where  $y_0$  is chosen such that the integral of  $p(y)$  over all  $y$  is one.

In terms of the tensile-strength table previously given, the respective chi-square sample values for the daily, weekly, and monthly figures could be computed. The corresponding df would be 4, 24, and 99 respectively. These numbers would represent sample values from the respective distributions which are summarized in Table 3-7.

In a manner similar to the use of the *t* distribution, chi square can be interpreted in a direct probabilistic sense corresponding to a midarea of  $(1 - \alpha)$ :

$$P[\chi_1^2 \leq (s^2/\sigma^2)(df) \leq \chi_2^2] = 1 - \alpha$$

where  $\chi_1^2$  corresponds to a lower-tail area of  $\alpha/2$  and  $\chi_2^2$  an upper-tail area of  $\alpha/2$ .

The basic underlying assumption for the mathematical derivation of chi square is that a random sample was selected from a normal distribution with variance  $\sigma^2$ . When the population is not normal but skewed, chi-square probabilities could be substantially in error.

**Example** On the basis of a sample size  $n = 5$ , what midrange of values will include the sample ratio  $s/\sigma$  with a probability of 95 percent?

Use Table 3-7 for 4 df and read  $\chi_1^2 = 0.484$  for a lower tail area of 0.05/2, 2.5 percent, and read  $\chi_2^2 = 11.1$  for an upper tail area of 97.5 percent.

$$P[.484 \leq (s^2/\sigma^2)(4) \leq 11.1] = .95$$

or 
$$P[.35 \leq s/\sigma \leq 1.66] = .95$$

The Microsoft Excel functions CHIINV(.025, 4) and CHIINV(.975, 4) give the same values.

**Example** On the basis of a sample size  $n = 25$ , what midrange of values will include the sample ratio  $s/\sigma$  with a probability of 95 percent?

$$P[12.4 \leq (s^2/\sigma^2)(24) \leq 39.4] = .95$$

or 
$$P[.72 \leq s/\sigma \leq 1.28] = .95$$

This states that the sample standard deviation will be at least 72 percent and not more than 128 percent of the population variance 95 percent of the time. Conversely, 10 percent of the time the standard deviation will underestimate or overestimate the population standard deviation by the corresponding amount. Even for samples as large as 25, the relative reliability of a sample standard deviation is poor.

The chi-square distribution can be applied to other types of application which are of an entirely different nature. These include applications which are discussed under "Goodness-of-Fit Test" and "Two-Way Test for Independence of Count Data." In these applications, the mathematical formulation and context are entirely different, but they do result in the same table of values.

**F Distribution** In reference to the tensile-strength table, the successive pairs of daily standard deviations could be ratioed and squared. These ratios of variance would represent a sample from a distribution called the *F* distribution or *F* ratio. In general, the *F* ratio is defined by the identity

$$F(\gamma_1, \gamma_2) = s_1^2/s_2^2$$

where  $\gamma_1$  and  $\gamma_2$  correspond to the respective df's for the sample variances. In statistical applications, it turns out that the primary area of interest is found when the ratios are greater than 1. For this reason, most tabled values are defined for an upper-tail area. However,

TABLE 3-7 Percentiles of the  $\chi^2$  Distribution

| df  | Percent  |         |         |        |        |        |        |        |        |        |
|-----|----------|---------|---------|--------|--------|--------|--------|--------|--------|--------|
|     | 0.5      | 1       | 2.5     | 5      | 10     | 90     | 95     | 97.5   | 99     | 99.5   |
| 1   | 0.000039 | 0.00016 | 0.00098 | 0.0039 | 0.0158 | 2.71   | 3.84   | 5.02   | 6.63   | 7.88   |

| 120 | 83.85    | 86.92   | 91.58   | 95.70  | 100.62 | 140.23 | 146.57 | 152.21 | 158.95 | 163.64 |

For large values of degrees of freedom the approximate formula

$$\chi^2_\alpha = n \left( 1 - \frac{2}{9n} + z_\alpha \sqrt{\frac{2}{9n}} \right)^3$$

where  $z_\alpha$  is the normal deviate and  $n$  is the number of degrees of freedom, may be used. For example,  $\chi^2_{.99} = 60[1 - 0.00370 + 2.326(0.06086)]^3 = 60(1.1379)^3 = 88.4$  for the 99th percentile for 60 degrees of freedom. The Microsoft Excel function CHIDIST( $X$ ,  $df$ ), where  $X$  is the table value, gives 1 - Percent. The function CHIINV(1 - Percent,  $df$ ) gives the table value.

defining  $F_2$  to be that value corresponding to an upper-tail area of  $\alpha/2$ , then  $F_1$  for a lower-tail area of  $\alpha/2$  can be determined through the identity

$$F_1(\gamma_1, \gamma_2) = 1/F_2(\gamma_2, \gamma_1)$$

The  $F$  distribution, similar to the chi square, is sensitive to the basic assumption that sample values were selected randomly from a normal distribution. The Microsoft Excel function FDIST( $X$ ,  $df_1$ ,  $df_2$ ) gives the upper percent points of Table 3-8, where  $X$  is the tabular value. The function FINV(Percent,  $df_1$ ,  $df_2$ ) gives the table value.

**Example** For two sample variances with 4 df each, what limits will bracket their ratio with a midarea probability of 90 percent?

Use Table 3-8 with 4 df in the numerator and denominator and upper 5 percent points (to get both sides totaling 10 percent). The entry is 6.39. Thus:

$$P[1/6.39 \leq s_1^2/s_2^2 \leq 6.39] = .90$$

or 
$$P[.40 \leq s_1/s_2 \leq 2.53] = .90$$

The Microsoft Excel function FINV(.05, 4, 4) gives 6.39, too.

**Confidence Interval for a Mean** For the daily sample tensile-strength data with 4 df it is known that  $P[-2.132 \leq t \leq 2.132] = .90$ . This states that 90 percent of all samples will have sample  $t$  values which fall within the specified limits. In fact, for the 20 daily samples exactly 16 do fall within the specified limits (note that the binomial with  $n = 20$  and  $p = .90$  would describe the likelihood of exactly none through 20 falling within the prescribed limits—the sample of 20 is only a sample).

Consider the new daily sample (with  $n = 5$ ,  $\bar{x} = 37.14$ , and  $s = 1.85$ ) which was observed after a process change. In this case, the same probability holds. However, in this instance the sample value of  $t$  cannot be computed, since the new  $\mu$ , under the process change, is not known. Therefore  $P[-2.132 \leq (37.14 - \mu)/(1.85/\sqrt{5}) \leq 2.132] = .90$ . In effect, this identity limits the magnitude of possible values for

$\mu$ . The magnitude of  $\mu$  can be only large enough to retain the  $t$  quantity above  $-2.132$  and small enough to retain the  $t$  quantity below  $+2.132$ . This can be found by rearranging the quantities within the bracket; i.e.,  $P[35.38 \leq \mu \leq 38.90] = .90$ . This states that we are 90 percent sure that the interval from 35.38 to 38.90 includes the unknown parameter  $\mu$ .

In general,

$$P\left[\bar{x} - t \frac{s}{\sqrt{n}} \leq \mu \leq \bar{x} + t \frac{s}{\sqrt{n}}\right] = 1 - \alpha$$

where  $t$  is defined for an upper-tail area of  $\alpha/2$  with  $(n - 1)$  df. In this application, the interval limits  $(\bar{x} \pm t s/\sqrt{n})$  are random variables which will cover the unknown parameter  $\mu$  with probability  $(1 - \alpha)$ . The converse, that we are  $100(1 - \alpha)$  percent sure that the parameter value is within the interval, is not correct. This statement defines a probability for the parameter rather than the probability for the interval.

**Example** What values of  $t$  define the midarea of 95 percent for weekly samples of size 25, and what is the sample value of  $t$  for the second week?

$$P[-2.064 \leq t \leq 2.064] = .95$$

and 
$$(34.19 - 35)/(2.35/\sqrt{25}) = 1.72.$$

**Example** For the composite sample of 100 tensile strengths, what is the 90 percent confidence interval for  $\mu$ ?

Use Table 3-6 for  $t_{.05}$  with  $df = \infty$ .

$$P\left[35.16 - 1.645 \frac{2.47}{\sqrt{100}} < \mu < 35.16 + 1.645 \frac{2.47}{\sqrt{100}}\right] = .90$$

or 
$$P[34.75 \leq \mu \leq 35.57] = .90$$

**Confidence Interval for the Difference in Two Population Means** The confidence interval for a mean can be extended to

TABLE 3-8 F Distribution

|                                    | 16   | 4.49                             | 3.63 | 3.24 | 3.01 | 2.85 | 2.74 | 2.66 | 2.59 | 2.54 | 2.49 | 2.42 | 2.35 | 2.28 | 2.24 | 2.19 | 2.15 | 2.11 | 2.06 | 2.01     | 2.01 |
|                                    | 17   | 4.45                             | 3.59 | 3.20 | 2.96 | 2.81 | 2.70 | 2.61 | 2.55 | 2.49 | 2.45 | 2.38 | 2.31 | 2.23 | 2.19 | 2.15 | 2.10 | 2.06 | 2.01 | 1.96     | 1.96 |
|                                    | 18   | 4.41                             | 3.55 | 3.16 | 2.93 | 2.77 | 2.66 | 2.58 | 2.51 | 2.46 | 2.41 | 2.34 | 2.27 | 2.19 | 2.15 | 2.11 | 2.06 | 2.02 | 1.97 | 1.92     | 1.92 |
|                                    | 19   | 4.38                             | 3.52 | 3.13 | 2.90 | 2.74 | 2.63 | 2.54 | 2.48 | 2.42 | 2.38 | 2.31 | 2.23 | 2.16 | 2.11 | 2.07 | 2.03 | 1.98 | 1.93 | 1.88     | 1.88 |
|                                    | 20   | 4.35                             | 3.49 | 3.10 | 2.87 | 2.71 | 2.60 | 2.51 | 2.45 | 2.39 | 2.35 | 2.28 | 2.20 | 2.12 | 2.08 | 2.04 | 1.99 | 1.95 | 1.90 | 1.84     | 1.84 |
|                                    | 21   | 4.32                             | 3.47 | 3.07 | 2.84 | 2.68 | 2.57 | 2.49 | 2.42 | 2.37 | 2.32 | 2.25 | 2.18 | 2.10 | 2.05 | 2.01 | 1.96 | 1.92 | 1.87 | 1.81     | 1.81 |
|                                    | 22   | 4.30                             | 3.44 | 3.05 | 2.82 | 2.66 | 2.55 | 2.46 | 2.40 | 2.34 | 2.30 | 2.23 | 2.15 | 2.07 | 2.03 | 1.98 | 1.94 | 1.89 | 1.84 | 1.78     | 1.78 |
|                                    | 23   | 4.28                             | 3.42 | 3.03 | 2.80 | 2.64 | 2.53 | 2.44 | 2.37 | 2.32 | 2.27 | 2.20 | 2.13 | 2.05 | 2.01 | 1.96 | 1.91 | 1.86 | 1.81 | 1.76     | 1.76 |
|                                    | 24   | 4.26                             | 3.40 | 3.01 | 2.78 | 2.62 | 2.51 | 2.42 | 2.36 | 2.30 | 2.25 | 2.18 | 2.11 | 2.03 | 1.98 | 1.94 | 1.89 | 1.84 | 1.79 | 1.73     | 1.73 |
|                                    | 25   | 4.24                             | 3.39 | 2.99 | 2.76 | 2.60 | 2.49 | 2.40 | 2.34 | 2.28 | 2.24 | 2.16 | 2.09 | 2.01 | 1.96 | 1.92 | 1.87 | 1.82 | 1.77 | 1.71     | 1.71 |
| 30                                 | 4.17 | 3.32                             | 2.92 | 2.69 | 2.53 | 2.42 | 2.33 | 2.27 | 2.21 | 2.16 | 2.09 | 2.01 | 1.93 | 1.89 | 1.84 | 1.79 | 1.74 | 1.68 | 1.62 | 1.62     |      |
| 40                                 | 4.08 | 3.23                             | 2.84 | 2.61 | 2.45 | 2.34 | 2.25 | 2.18 | 2.12 | 2.08 | 2.00 | 1.92 | 1.84 | 1.79 | 1.74 | 1.69 | 1.64 | 1.58 | 1.51 | 1.51     |      |
| 60                                 | 4.00 | 3.15                             | 2.76 | 2.53 | 2.37 | 2.25 | 2.17 | 2.10 | 2.04 | 1.99 | 1.92 | 1.84 | 1.75 | 1.70 | 1.65 | 1.59 | 1.53 | 1.47 | 1.39 | 1.39     |      |
| 120                                | 3.92 | 3.07                             | 2.68 | 2.45 | 2.29 | 2.18 | 2.09 | 2.02 | 1.96 | 1.91 | 1.83 | 1.75 | 1.66 | 1.61 | 1.55 | 1.50 | 1.43 | 1.35 | 1.25 | 1.25     |      |
| $\infty$                           | 3.84 | 3.00                             | 2.60 | 2.37 | 2.21 | 2.10 | 2.01 | 1.94 | 1.88 | 1.83 | 1.75 | 1.67 | 1.57 | 1.52 | 1.46 | 1.39 | 1.32 | 1.22 | 1.00 | 1.00     |      |

Interpolation should be performed using reciprocals of the degrees of freedom.

include the difference between two population means. This interval is based on the assumption that the respective populations have the same variance  $\sigma^2$ :

$$(\bar{x}_1 - \bar{x}_2) - t_{s_p} \sqrt{1/n_1 + 1/n_2} \leq \mu_1 - \mu_2 \leq (\bar{x}_1 - \bar{x}_2) + t_{s_p} \sqrt{1/n_1 + 1/n_2}$$

**Example** Compute the 95 percent confidence interval based on the original 100-point sample and the subsequent 5-point sample:

$$s_p^2 = \frac{99(2.47)^2 + 4(1.85)^2}{103} = 5.997$$

or  $s_p = 2.45$

With 103 df and  $\alpha = .05$ ,  $t = \pm 1.96$  using  $t_{.025}$  in Table 3-6. Therefore

$$(35.16 - 37.14) \pm 1.96(2.45) \sqrt{1/100 + 1/5} = -1.98 \pm 2.20$$

or  $-4.18 \leq (\mu_1 - \mu_2) \leq .22$

Note that if the respective samples had been based on 52 observations each rather than 100 and 5, the uncertainty factor would have been  $\pm .94$  rather than the observed  $\pm 2.20$ . The interval width tends to be minimum when  $n_1 = n_2$ .

**Confidence Interval for a Variance** The chi-square distribution can be used to derive a confidence interval for a population variance  $\sigma^2$  when the parent population is normally distributed. For a  $100(1 - \alpha)$  percent confidence interval

$$\frac{(df)s^2}{\chi^2_2} \leq \sigma^2 \leq \frac{(df)s^2}{\chi^2_1}$$

where  $\chi^2_1$  corresponds to a lower-tail area of  $\alpha/2$  and  $\chi^2_2$  to an upper-tail area of  $\alpha/2$ .

**Example** For the first week of tensile-strength samples compute the 90 percent confidence interval for  $\sigma^2$  (df = 24, corresponding to  $n = 25$ , using 5 percent and 95 percent in Table 3-7):

$$\frac{24(2.40)^2}{36.4} \leq \sigma^2 \leq \frac{24(2.40)^2}{13.8}$$

$$3.80 \leq \sigma^2 \leq 10.02$$

or

$$1.95 \leq \sigma \leq 3.17$$

**TESTS OF HYPOTHESIS**

**General Nature of Tests** The general nature of tests can be illustrated with a simple example. In a court of law, when a defendant is charged with a crime, the judge instructs the jury initially to presume that the defendant is innocent of the crime. The jurors are then presented with evidence and counterargument as to the defendant's guilt or innocence. If the evidence suggests beyond a reasonable doubt that the defendant did, in fact, commit the crime, they have been instructed to find the defendant guilty; otherwise, not guilty. The burden of proof is on the prosecution.

Jury trials represent a form of decision making. In statistics, an analogous procedure for making decisions falls into an area of statistical inference called **hypothesis testing**.

Suppose that a company has been using a certain supplier of raw materials in one of its chemical processes. A new supplier approaches the company and states that its material, at the same cost, will increase the process yield. If the new supplier has a good reputation, the company might be willing to run a limited test. On the basis of the test results it would then make a decision to change suppliers or not. Good management would dictate that an improvement must be demonstrated

(beyond a reasonable doubt) for the new material. That is, the burden of proof is tied to the new material. In setting up a test of hypothesis for this application, the initial assumption would be defined as a null hypothesis and symbolized as  $H_0$ . The null hypothesis would state that yield for the new material is no greater than for the conventional material. The symbol  $\mu_0$  would be used to designate the known current level of yield for the standard material and  $\mu$  for the unknown population yield for the new material. Thus, the null hypothesis can be symbolized as  $H_0: \mu \leq \mu_0$ .

The alternative to  $H_0$  is called the alternative hypothesis and is symbolized as  $H_1: \mu > \mu_0$ .

Given a series of tests with the new material, the average yield  $\bar{x}$  would be compared with  $\mu_0$ . If  $\bar{x} < \mu_0$ , the new supplier would be dismissed. If  $\bar{x} > \mu_0$ , the question would be: Is it sufficiently greater in the light of its corresponding reliability, i.e., beyond a reasonable doubt? If the confidence interval for  $\mu$  included  $\mu_0$ , the answer would be no, but if it did not include  $\mu_0$ , the answer would be yes. In this simple application, the formal test of hypothesis would result in the same conclusion as that derived from the confidence interval. However, the utility of tests of hypothesis lies in their generality, whereas confidence intervals are restricted to a few special cases.

**Test of Hypothesis for a Mean Procedure**

**Nomenclature**

- $\mu$  = mean of the population from which the sample has been drawn
- $\sigma$  = standard deviation of the population from which the sample has been drawn
- $\mu_0$  = base or reference level
- $H_0$  = null hypothesis
- $H_1$  = alternative hypothesis
- $\alpha$  = significance level, usually set at .10, .05, or .01
- $t$  = tabled  $t$  value corresponding to the significance level  $\alpha$ . For a two-tailed test, each corresponding tail would have an area of  $\alpha/2$ , and for a one-tailed test, one tail area would be equal to  $\alpha$ . If  $\sigma^2$  is known, then  $z$  would be used rather than the  $t$ .
- $t = (\bar{x} - \mu_0)/(s/\sqrt{n})$  = sample value of the test statistic.

**Assumptions**

1. The  $n$  observations  $x_1, x_2, \dots, x_n$  have been selected randomly.
2. The population from which the observations were obtained is normally distributed with an unknown mean  $\mu$  and standard deviation  $\sigma$ . In actual practice, this is a robust test, in the sense that in most types of problems it is not sensitive to the normality assumption when the sample size is 10 or greater.

**Test of Hypothesis**

1. Under the null hypothesis, it is assumed that the sample came from a population whose mean  $\mu$  is equivalent to some base or reference designated by  $\mu_0$ . This can take one of three forms:

| Form 1                | Form 2                | Form 3                |
|-----------------------|-----------------------|-----------------------|
| $H_0: \mu = \mu_0$    | $H_0: \mu \leq \mu_0$ | $H_0: \mu \geq \mu_0$ |
| $H_1: \mu \neq \mu_0$ | $H_1: \mu > \mu_0$    | $H_1: \mu < \mu_0$    |
| Two-tailed test       | Upper-tailed test     | Lower-tailed test     |

2. If the null hypothesis is assumed to be true, say, in the case of a two-sided test, form 1, then the distribution of the test statistic  $t$  is known. Given a random sample, one can predict how far its sample value of  $t$  might be expected to deviate from zero (the midvalue of  $t$ ) by chance alone. If the sample value of  $t$  does, in fact, deviate too far from zero, then this is defined to be sufficient evidence to refute the assumption of the null hypothesis. It is consequently rejected, and the converse or alternative hypothesis is accepted.

3. The rule for accepting  $H_0$  is specified by selection of the  $\alpha$  level as indicated in Fig. 3-65. For forms 2 and 3 the  $\alpha$  area is defined to be in the upper or the lower tail respectively. The parameter  $\alpha$  is the probability of rejecting the null hypothesis when it is actually true.

4. The decision rules for each of the three forms are defined as follows: If the sample  $t$  falls within the acceptance region, accept  $H_0$  for lack of contrary evidence. If the sample  $t$  falls in the critical region, reject  $H_0$  at a significance level of  $100\alpha$  percent.

**FIG. 3-65** Acceptance region for two-tailed test. For a one-tailed test, area =  $\alpha$  on one side only.

**Example**

**Application.** In the past, the yield for a chemical process has been established at 89.6 percent with a standard deviation of 3.4 percent. A new supplier of raw materials will be used and tested for 7 days.

**Procedure**

1. The standard of reference is  $\mu_0 = 89.6$  with a known  $\sigma = 3.4$ .
2. It is of interest to demonstrate whether an increase in yield is achieved with the new material;  $H_0$  says it has not; therefore,

$$H_0: \mu \leq 89.6 \quad H_1: \mu > 89.6$$

3. Select  $\alpha = .05$ , and since  $\sigma$  is known (the new material would not affect the day-to-day variability in yield), the test statistic would be  $z$  with a corresponding critical value  $cv(z) = 1.645$  (Table 3-6,  $df = \infty$ ).
4. The decision rule:

Accept  $H_0$  if sample  $z < 1.645$   
 Reject  $H_0$  if sample  $z > 1.645$

5. A 7-day test was carried out, and daily yields averaged 91.6 percent with a sample standard deviation  $s = 3.6$  (this is not needed for the test of hypothesis).
6. For the data sample  $z = (91.6 - 89.6)/(3.4/\sqrt{7}) = 1.56$ .
7. Since the sample  $z < cv(z)$ , accept the null hypothesis for lack of contrary evidence; i.e., an improvement has not been demonstrated beyond a reasonable doubt.

**Example**

**Application.** In the past, the break strength of a synthetic yarn has averaged 34.6 lb. The first-stage draw ratio of the spinning machines has been increased. Production management wants to determine whether the break strength has changed under the new condition.

**Procedure**

1. The standard of reference is  $\mu_0 = 34.6$ .
2. It is of interest to demonstrate whether a change has occurred; therefore,

$$H_0: \mu = 34.6 \quad H_1: \mu \neq 34.6$$

3. Select  $\alpha = .05$ , and since with the change in draw ratio the uniformity might change, the sample standard deviation would be used, and therefore  $t$  would be the appropriate test statistic.
4. A sample of 21 ends was selected randomly and tested on an Instron with the results  $\bar{x} = 35.55$  and  $s = 2.041$ .
5. For 20  $df$  and a two-tailed  $\alpha$  level of 5 percent, the critical values of  $t_{0.025}$  (two tailed) are given by  $\pm 2.086$  with a decision rule (Table 3-6,  $t_{0.025}$ ,  $df = 20$ ):

Accept  $H_0$  if  $-2.086 < \text{sample } t < 2.086$   
 Reject  $H_0$  if sample  $t < -2.086$  or  $> 2.086$

6. For the data sample  $t = (35.55 - 34.6)/(2.041/\sqrt{21}) = 2.133$ .
7. Since  $2.133 > 2.086$ , reject  $H_0$  and accept  $H_1$ . It has been demonstrated that an improvement in break strength has been achieved.

**Two-Population Test of Hypothesis for Means**

**Nature** Two samples were selected from different locations in a plastic-film sheet and measured for thickness. The thickness of the respective samples was measured at 10 close but equally spaced points in each of the samples. It was of interest to compare the average thickness of the respective samples to detect whether they were significantly different. That is, was there a significant variation in thickness between locations?

From a modeling standpoint statisticians would define this problem as a two-population test of hypothesis. They would define the respective sample sheets as two populations from which 10 sample thickness determinations were measured for each.

In order to compare populations based on their respective samples, it is necessary to have some basis of comparison. This basis is predicated on the distribution of the  $t$  statistic. In effect, the  $t$  statistic characterizes

the way in which two sample means from two separate populations will tend to vary by chance alone when the population means and variances are equal. Consider the following:

| Population 1 |             | Population 2 |             |
|--------------|-------------|--------------|-------------|
| Normal       | Sample 1    | Normal       | Sample 2    |
| $\mu_1$      | $n_1$       | $\mu_2$      | $n_2$       |
| $\sigma_1^2$ | $\bar{x}_1$ | $\sigma_2^2$ | $\bar{x}_2$ |
|              | $s_1^2$     |              | $s_2^2$     |

Consider the hypothesis  $\mu_1 = \mu_2$ . If, in fact, the hypothesis is correct, i.e.,  $\mu_1 = \mu_2$  (under the condition  $\sigma_1^2 = \sigma_2^2$ ), then the sampling distribution of  $(\bar{x}_1 - \bar{x}_2)$  is predictable through the  $t$  distribution. The observed sample values then can be compared with the corresponding  $t$  distribution. If the sample values are reasonably close (as reflected through the  $\alpha$  level), that is,  $\bar{x}_1$  and  $\bar{x}_2$  are not "too different" from each other on the basis of the  $t$  distribution, the null hypothesis would be accepted. Conversely, if they deviate from each other "too much" and the deviation is therefore not ascribable to chance, the conjecture would be questioned and the null hypothesis rejected.

**Example**

*Application.* Two samples were selected from different locations in a plastic-film sheet. The thickness of the respective samples was measured at 10 close but equally spaced points.

*Procedure*

1. Demonstrate whether the thicknesses of the respective sample locations are significantly different from each other; therefore,

$$H_0: \mu_1 = \mu_2 \quad H_1: \mu_1 \neq \mu_2$$

2. Select  $\alpha = .05$ .

3. Summarize the statistics for the respective samples:

| Sample 1            |               | Sample 2            |               |
|---------------------|---------------|---------------------|---------------|
| 1.473               | 1.367         | 1.474               | 1.417         |
| 1.484               | 1.276         | 1.501               | 1.448         |
| 1.484               | 1.485         | 1.485               | 1.469         |
| 1.425               | 1.462         | 1.435               | 1.474         |
| 1.448               | 1.439         | 1.348               | 1.452         |
| $\bar{x}_1 = 1.434$ | $s_1 = .0664$ | $\bar{x}_2 = 1.450$ | $s_2 = .0435$ |

4. As a first step, the assumption for the standard  $t$  test, that  $\sigma_1^2 = \sigma_2^2$ , can be tested through the  $F$  distribution. For this hypothesis,  $H_0: \sigma_1^2 = \sigma_2^2$  would be tested against  $H_1: \sigma_1^2 \neq \sigma_2^2$ . Since this is a two-tailed test and conventionally only the upper tail for  $F$  is published, the procedure is to use the largest ratio and the corresponding ordered degrees of freedom. This achieves the same end result through one table. However, since the largest ratio is arbitrary, it is necessary to define the true  $\alpha$  level as twice the value of the tabled value. Therefore, by using Table 3-8 with  $\alpha = .05$  the corresponding critical value for  $F(9,9) = 3.18$  would be for a true  $\alpha = .10$ . For the sample,

$$\text{Sample } F = (.0664/.0435)^2 = 2.33$$

Therefore, the ratio of sample variances is no larger than one might expect to observe when in fact  $\sigma_1^2 = \sigma_2^2$ . There is not sufficient evidence to reject the null hypothesis that  $\sigma_1^2 = \sigma_2^2$ .

5. For 18 df and a two-tailed  $\alpha$  level of 5 percent the critical values of  $t$  are given by  $\pm 2.101$  (Table 3-6,  $t_{0.025}, df = 18$ ).

6. The decision rule:

- Accept  $H_0$  if  $-2.101 \leq \text{sample } t \leq 2.101$
- Reject  $H_0$  otherwise

7. For the sample the pooled variance estimate is given by Eq. (3-120).

$$s_p^2 = \frac{9(.0664)^2 + 9(.0435)^2}{9 + 9} = \frac{(.0664)^2 + (.0435)^2}{2} = .00315$$

or  $s_p = .056$

8. The sample statistic value of  $t$  is given by Eq. (3-119).

$$\text{Sample } t = \frac{1.434 - 1.450}{.056\sqrt{1/10 + 1/10}} = -.64$$

9. Since the sample value of  $t$  falls within the acceptance region, accept  $H_0$  for lack of contrary evidence; i.e., there is insufficient evidence to demonstrate that thickness differs between the two selected locations.

**Test of Hypothesis for Paired Observations**

**Nature** In some types of applications, associated pairs of observations are defined. For example, (1) pairs of samples from two populations are treated in the same way, or (2) two types of measurements are made on the same unit. For applications of this type, it is not only more effective but necessary to define the random variable as the difference between the pairs of observations. The difference numbers can then be tested by the standard  $t$  distribution.

Examples of the two types of applications are as follows:

1. *Sample treatment*

- a. Two types of metal specimens buried in the ground together in a variety of soil types to determine corrosion resistance
- b. Wear-rate test with two different types of tractor tires mounted in pairs on  $n$  tractors for a defined period of time

2. *Same unit*

- a. Blood-pressure measurements made on the same individual before and after the administration of a stimulus
- b. Smoothness determinations on the same film samples at two different testing laboratories

**Test of Hypothesis for Matched Pairs: Procedure**

**Nomenclature**

- $d_i$  = sample difference between the  $i$ th pair of observations
- $s$  = sample standard deviation of differences
- $\mu$  = population mean of differences
- $\sigma$  = population standard deviation of differences
- $\mu_0$  = base or reference level of comparison
- $H_0$  = null hypothesis
- $H_1$  = alternative hypothesis
- $\alpha$  = significance level
- $t$  = tabled value with  $(n - 1)$  df
- $t = (\bar{d} - \mu_0)/(s/\sqrt{n})$ , the sample value of  $t$

**Assumptions**

- 1. The  $n$  pairs of samples have been selected and assigned for testing in a random way.
- 2. The population of differences is normally distributed with a mean  $\mu$  and variance  $\sigma^2$ . As in the previous application of the  $t$  distribution, this is a robust procedure, i.e., not sensitive to the normality assumption if the sample size is 10 or greater in most situations.

**Test of Hypothesis**

1. Under the null hypothesis, it is assumed that the sample came from a population whose mean  $\mu$  is equivalent to some base or reference level designated by  $\mu_0$ . For most applications of this type, the value of  $\mu_0$  is defined to be zero; that is, it is of interest generally to demonstrate a difference not equal to zero. The hypothesis can take one of three forms:

| Form 1                | Form 2                | Form 3                |
|-----------------------|-----------------------|-----------------------|
| $H_0: \mu = \mu_0$    | $H_0: \mu \leq \mu_0$ | $H_0: \mu \geq \mu_0$ |
| $H_1: \mu \neq \mu_0$ | $H_1: \mu > \mu_0$    | $H_1: \mu < \mu_0$    |
| Two-tailed test       | Upper-tailed test     | Lower-tailed test     |

2. If the null hypothesis is assumed to be true, say, in the case of a lower-tailed test, form 3, then the distribution of the test statistic  $t$  is known under the null hypothesis that limits  $\mu = \mu_0$ . Given a random sample, one can predict how far its sample value of  $t$  might be expected to deviate from zero by chance alone when  $\mu = \mu_0$ . If the sample value of  $t$  is too small, as in the case of a negative value, then this would be defined as sufficient evidence to reject the null hypothesis.

3. Select  $\alpha$ .

4. The critical values or value of  $t$  would be defined by the tabled value of  $t$  with  $(n - 1)$  df corresponding to a tail area of  $\alpha$ . For a two-tailed test, each tail area would be  $\alpha/2$ , and for a one-tailed test there would be an upper-tail or a lower-tail area of  $\alpha$  corresponding to forms 2 and 3 respectively.

5. The decision rule for each of the three forms would be to reject the null hypothesis if the sample value of  $t$  fell in that area of the  $t$  distribution defined by  $\alpha$ , which is called the critical region.

Otherwise, the alternative hypothesis would be accepted for lack of contrary evidence.

**Example**

*Application.* Pairs of pipes have been buried in 11 different locations to determine corrosion on nonbituminous pipe coatings for underground use. One type includes a lead-coated steel pipe and the other a bare steel pipe.

*Procedure*

1. The standard of reference is taken as  $\mu_0 = 0$ , corresponding to no difference in the two types.
2. It is of interest to demonstrate whether either type of pipe has a greater corrosion resistance than the other. Therefore,

$$H_0: \mu = 0 \quad H_1: \mu \neq 0$$

3. Select  $\alpha = .05$ . Therefore, with  $n = 11$  the critical values of  $t$  with 10 df are defined by  $t = \pm 2.228$  (Table 3.5,  $t_{.025}$ ).
4. The decision rule:

Accept  $H_0$  if  $-2.228 \leq \text{sample } t \leq 2.228$   
 Reject  $H_0$  otherwise

5. The sample of 11 pairs of corrosion determinations and their differences are as follows:

| Soil type | Lead-coated steel pipe | Bare steel pipe | $d = \text{difference}$ |
|-----------|------------------------|-----------------|-------------------------|
| A         | 27.3                   | 41.4            | -14.1                   |
| B         | 18.4                   | 18.9            | -0.5                    |
| C         | 11.9                   | 21.7            | -9.8                    |
| D         | 11.3                   | 16.8            | -5.5                    |
| E         | 14.8                   | 9.0             | 5.8                     |
| F         | 20.8                   | 19.3            | 1.5                     |
| G         | 17.9                   | 32.1            | -14.2                   |
| H         | 7.8                    | 7.4             | 0.4                     |
| I         | 14.7                   | 20.7            | -6.0                    |
| J         | 19.0                   | 34.4            | -15.4                   |
| K         | 65.3                   | 76.2            | -10.9                   |

6. The sample statistics, Eq. (3-118)

$$\bar{d} = -6.245 \quad s^2 = \frac{11 \sum d^2 - (\sum d)^2}{11 \times 10} = 52.59$$

or

$$s = 7.25$$

$$\text{Sample } t = \frac{(-6.245 - 0)/(7.25/\sqrt{11})}{-2.86}$$

7. Since the sample  $t$  of  $-2.86 <$  tabled  $t$  of  $-2.228$ , reject  $H_0$  and accept  $H_1$ ; that is, it has been demonstrated that, on the basis of the evidence, lead-coated steel pipe has a greater corrosion resistance than bare steel pipe.

**Example**

*Application.* A stimulus was tested for its effect on blood pressure. Ten men were selected randomly, and their blood pressure was measured before and after the stimulus was administered. It was of interest to determine whether the stimulus had caused a significant increase in the blood pressure.

*Procedure*

1. The standard of reference was taken as  $\mu_0 \leq 0$ , corresponding to no increase.
2. It was of interest to demonstrate an increase in blood pressure if in fact an increase did occur. Therefore,

$$H_0: \mu_0 \leq 0 \quad H_1: \mu_0 > 0$$

3. Select  $\alpha = .05$ . Therefore, with  $n = 10$  the critical value of  $t$  with 9 df is defined by  $t = 1.833$  (Table 3-6,  $t_{.05}$ , one-sided).
4. The decision rule:

Accept  $H_0$  if sample  $t < 1.833$   
 Reject  $H_0$  if sample  $t > 1.833$

5. The sample of 10 pairs of blood pressure and their differences were as follows:

| Individual | Before | After | $d = \text{difference}$ |
|------------|--------|-------|-------------------------|
| 1          | 138    | 146   | 8                       |
| 2          | 116    | 118   | 2                       |
| 3          | 124    | 120   | -4                      |
| 4          | 128    | 136   | 8                       |

|    |     |     |    |
|----|-----|-----|----|
| 5  | 155 | 174 | 19 |
| 6  | 129 | 133 | 4  |
| 7  | 130 | 129 | -1 |
| 8  | 148 | 155 | 7  |
| 9  | 143 | 148 | 5  |
| 10 | 159 | 155 | -4 |

6. The sample statistics:

$$\bar{d} = 4.4 \quad s = 6.85$$

$$\text{Sample } t = (4.4 - 0)/(6.85/\sqrt{10}) = 2.03$$

7. Since the sample  $t = 2.03 >$  critical  $t = 1.833$ , reject the null hypothesis. It has been demonstrated that the population of men from which the sample was drawn tend, as a whole, to have an increase in blood pressure after the stimulus has been given. The distribution of differences  $d$  seems to indicate that the degree of response varies by individuals.

**Test of Hypothesis for a Proportion**

**Nature** Some types of statistical applications deal with counts and proportions rather than measurements. Examples are (1) the proportion of workers in a plant who are out sick, (2) lost-time worker accidents per month, (3) defective items in a shipment lot, and (4) preference in consumer surveys.

The procedure for testing the significance of a sample proportion follows that for a sample mean. In this case, however, owing to the nature of the problem the appropriate test statistic is  $Z$ . This follows from the fact that the null hypothesis requires the specification of the goal or reference quantity  $p_0$ , and since the distribution is a binomial proportion, the associated variance is  $[p_0(1 - p_0)]n$  under the null hypothesis. The primary requirement is that the sample size  $n$  satisfy normal approximation criteria for a binomial proportion, roughly  $np > 5$  and  $n(1 - p) > 5$ .

**Test of Hypothesis for a Proportion: Procedure**

**Nomenclature**

$p$  = mean proportion of the population from which the sample has been drawn

$p_0$  = base or reference proportion

$[p_0(1 - p_0)]/n$  = base or reference variance

$\hat{p} = x/n$  = sample proportion, where  $x$  refers to the number of observations out of  $n$  which have the specified attribute

$H_0$  = assumption or null hypothesis regarding the population proportion

$H_1$  = alternative hypothesis

$\alpha$  = significance level, usually set at .10, .05, or .01

$z$  = tabled  $Z$  value corresponding to the significance level  $\alpha$ . The sample sizes required for the  $z$  approximation according to the magnitude of  $p_0$  are given in Table 3-6.

$z = (\hat{p} - p_0)/\sqrt{p_0(1 - p_0)/n}$ , the sample value of the test statistic

**Assumptions**

1. The  $n$  observations have been selected randomly.
2. The sample size  $n$  is sufficiently large to meet the requirement for the  $Z$  approximation.

**Test of Hypothesis**

1. Under the null hypothesis, it is assumed that the sample came from a population with a proportion  $p_0$  of items having the specified attribute. For example, in tossing a coin the population could be thought of as having an unbounded number of potential tosses. If it is assumed that the coin is fair, this would dictate  $p_0 = 1/2$  for the proportional number of heads in the population. The null hypothesis can take one of three forms:

| Form 1            | Form 2            | Form 3            |
|-------------------|-------------------|-------------------|
| $H_0: p = p_0$    | $H_0: p \leq p_0$ | $H_0: p \geq p_0$ |
| $H_1: p \neq p_0$ | $H_1: p > p_0$    | $H_1: p < p_0$    |
| Two-tailed test   | Upper-tailed test | Lower-tailed test |

2. If the null hypothesis is assumed to be true, then the sampling distribution of the test statistic  $Z$  is known. Given a random sample, it is possible to predict how far the sample proportion  $x/n$  might deviate from its assumed population proportion  $p_0$  through the  $Z$  distribution. When the sample proportion deviates too far, as defined by the significance level  $\alpha$ , this serves as the justification for rejecting the assumption, that is, rejecting the null hypothesis.

3. The decision rule is given by  
 Form 1: Accept  $H_0$  if lower critical  $z < \text{sample } z < \text{upper critical } z$   
 Reject  $H_0$  otherwise  
 Form 2: Accept  $H_0$  if sample  $z < \text{upper critical } z$   
 Reject  $H_0$  otherwise  
 Form 3: Accept  $H_0$  if lower critical  $z < \text{sample } z$   
 Reject  $H_0$  otherwise

**Example**

*Application.* A company has received a very large shipment of rivets. One product specification required that no more than 2 percent of the rivets have diameters greater than 14.28 mm. Any rivet with a diameter greater than this would be classified as defective. A random sample of 600 was selected and tested with a go-no-go gauge. Of these, 16 rivets were found to be defective. Is this sufficient evidence to conclude that the shipment contains more than 2 percent defective rivets?

*Procedure*

- The quality goal is  $p \leq .02$ . It would be assumed initially that the shipment meets this standard; i.e.,  $H_0: p \leq .02$ .
- The assumption in step 1 would first be tested by obtaining a random sample. Under the assumption that  $p \leq .02$ , the distribution for a sample proportion would be defined by the  $z$  distribution. This distribution would define an upper bound corresponding to the upper critical value for the sample proportion. It would be unlikely that the sample proportion would rise above that value if, in fact,  $p \leq .02$ . If the observed sample proportion exceeds that limit, corresponding to what would be a very unlikely chance outcome, this would lead one to question the assumption that  $p \leq .02$ . That is, one would conclude that the null hypothesis is false. To test, set

$$H_0: p \leq .02 \quad H_1: p > .02$$

- Select  $\alpha = .05$ .
- With  $\alpha = .05$ , the upper critical value of  $Z = 1.645$  (Table 3-6,  $t_{.05}$ ,  $df = \infty$ , one-sided).
- The decision rule:

$$\begin{aligned} &\text{Accept } H_0 \text{ if sample } z < 1.645 \\ &\text{Reject } H_0 \text{ if sample } z > 1.645 \end{aligned}$$

6. The sample  $z$  is given by

$$\begin{aligned} \text{Sample } z &= \frac{(16/600) - .02}{\sqrt{(.02)(.98)/600}} \\ &= 1.17 \end{aligned}$$

7. Since the sample  $z < 1.645$ , accept  $H_0$  for lack of contrary evidence; there is not sufficient evidence to demonstrate that the defect proportion in the shipment is greater than 2 percent.

**Test of Hypothesis for Two Proportions**

*Nature* In some types of engineering and management-science problems, we may be concerned with a random variable which represents a proportion, for example, the proportional number of defective items per day. The method described previously relates to a single proportion. In this subsection two proportions will be considered.

A certain change in a manufacturing procedure for producing component parts is being considered. Samples are taken by using both the existing and the new procedures in order to determine whether the new procedure results in an improvement. In this application, it is of interest to demonstrate statistically whether the population proportion  $p_2$  for the new procedure is less than the population proportion  $p_1$  for the old procedure on the basis of a sample of data.

**Test of Hypothesis for Two Proportions: Procedure**

*Nomenclature*

- $p_1$  = population 1 proportion
- $p_2$  = population 2 proportion
- $n_1$  = sample size from population 1
- $n_2$  = sample size from population 2

- $x_1$  = number of observations out of  $n_1$  that have the designated attribute
- $x_2$  = number of observations out of  $n_2$  that have the designated attribute

- $\hat{p}_1 = x_1/n_1$ , the sample proportion from population 1
- $\hat{p}_2 = x_2/n_2$ , the sample proportion from population 2
- $\alpha$  = significance level

- $H_0$  = null hypothesis
- $H_1$  = alternative hypothesis
- $z$  = tabled  $Z$  value corresponding to the stated significance level  $\alpha$
- $z = \frac{\hat{p}_1 - \hat{p}_2}{\sqrt{\hat{p}_1(1 - \hat{p}_1)/n_1 + \hat{p}_2(1 - \hat{p}_2)/n_2}}$ , the sample value of  $Z$

**Assumptions**

- The respective two samples of  $n_1$  and  $n_2$  observations have been selected randomly.
- The sample sizes  $n_1$  and  $n_2$  are sufficiently large to meet the requirement for the  $Z$  approximation; i.e.,  $x_1 > 5$ ,  $x_2 > 5$ .

**Test of Hypothesis**

1. Under the null hypothesis, it is assumed that the respective two samples have come from populations with equal proportions  $p_1 = p_2$ . Under this hypothesis, the sampling distribution of the corresponding  $Z$  statistic is known. On the basis of the observed data, if the resultant sample value of  $Z$  represents an unusual outcome, that is, if it falls within the critical region, this would cast doubt on the assumption of equal proportions. Therefore, it will have been demonstrated statistically that the population proportions are in fact not equal. The various hypotheses can be stated:

| Form 1              | Form 2              | Form 3              |
|---------------------|---------------------|---------------------|
| $H_0: p_1 = p_2$    | $H_0: p_1 \leq p_2$ | $H_0: p_1 \geq p_2$ |
| $H_1: p_1 \neq p_2$ | $H_1: p_1 > p_2$    | $H_1: p_1 < p_2$    |
| Two-tailed test     | Upper-tailed test   | Lower-tailed test   |

2. The decision rule for form 1 is given by  
 Accept  $H_0$  if lower critical  $z < \text{sample } z < \text{upper critical } z$   
 Reject  $H_0$  otherwise

**Example**

*Application.* A change was made in a manufacturing procedure for component parts. Samples were taken during the last week of operations with the old procedure and during the first week of operations with the new procedure. Determine whether the proportional numbers of defects for the respective populations differ on the basis of the sample information.

*Procedure*

- The hypotheses are  
 $H_0: p_1 = p_2 \quad H_1: p_1 \neq p_2$
- Select  $\alpha = .05$ . Therefore, the critical values of  $z$  are  $\pm 1.96$  (Table 3-5,  $A = 0.9500$ ).
- For the samples, 75 out of 1720 parts from the previous procedure and 80 out of 2780 parts under the new procedure were found to be defective; therefore,

$$\hat{p}_1 = 75/1720 = .0436 \quad \hat{p}_2 = 80/2780 = .0288$$

4. The decision rule:  
 Accept  $H_0$  if  $-1.96 \leq \text{sample } z \leq 1.96$   
 Reject  $H_0$  otherwise

5. The sample statistic:

$$\begin{aligned} \text{Sample } z &= \frac{.0436 - .0288}{\sqrt{(.0436)(.9564)/1720 + (.0288)(.9712)/2780}} \\ &= 2.53 \end{aligned}$$

6. Since the sample  $z$  of 2.53 > tabled  $z$  of 1.96, reject  $H_0$  and conclude that the new procedure has resulted in a reduced defect rate.

**Goodness-of-Fit Test**

*Nature* A standard die has six sides numbered from 1 to 6. If one were really interested in determining whether a particular die was well balanced, one would have to carry out an experiment. To do this, it might be decided to count the frequencies of outcomes, 1 through 6, in tossing the die  $N$  times. On the assumption that the die is perfectly balanced,

one would expect to observe  $N/6$  occurrences each for 1, 2, 3, 4, 5, and 6. However, chance dictates that exactly  $N/6$  occurrences each will not be observed. For example, given a perfectly balanced die, the probability is only 1 chance in 65 that one will observe 1 outcome each, for 1 through 6, in tossing the die 6 times. Therefore, an outcome different from 1 occurrence each can be expected. Conversely, an outcome of six 3s would seem to be too unusual to have occurred by chance alone.

Some industrial applications involve the concept outlined here. The basic idea is to test whether or not a group of observations follows a pre-conceived distribution. In the case cited, the distribution is uniform; i.e., each face value should tend to occur with the same frequency.

**Goodness-of-Fit Test: Procedure**

**Nomenclature** Each experimental observation can be classified into one of  $r$  possible categories or cells.

- $r$  = total number of cells
- $O_j$  = number of observations occurring in cell  $j$
- $E_j$  = expected number of observations for cell  $j$  based on the pre-conceived distribution
- $N$  = total number of observations
- $f$  = degrees of freedom for the test. In general, this will be equal to  $(r - 1)$  minus the number of statistical quantities on which the  $E_j$ s are based (see the examples which follow for details).

**Assumptions**

1. The observations represent a sample selected randomly from a population which has been specified.
2. The number of expectation counts  $E_j$  within each category should be roughly 5 or more. If an  $E_j$  count is significantly less than 5, that cell should be pooled with an adjacent cell.

**Computation for  $E_j$**  On the basis of the specified population, the probability of observing a count in cell  $j$  is defined by  $p_j$ . For a sample of size  $N$ , corresponding to  $N$  total counts, the expected frequency is given by  $E_j = Np_j$ .

**Test Statistics: Chi Square**

$$\chi^2 = \sum_{j=1}^r \frac{(O_j - E_j)^2}{E_j} \quad \text{with } f \text{ df}$$

**Test of Hypothesis**

1.  $H_0$ : The sample came from the specified theoretical distribution  
 $H_1$ : The sample did not come from the specified theoretical distribution
2. For a stated level of  $\alpha$ ,  
 Reject  $H_0$  if sample  $\chi^2 >$  tabled  $\chi^2$   
 Accept  $H_0$  if sample  $\chi^2 <$  tabled  $\chi^2$

**Example**

**Application** A production-line product is rejected if one of its characteristics does not fall within specified limits. The standard goal is that no more than 2 percent of the production should be rejected.

**Computation**

1. Of 950 units produced during the day, 28 units were rejected.
2. The hypotheses:  
 $H_0$ : the process is in control  
 $H_1$ : the process is not in control
3. Assume that  $\alpha = .05$ ; therefore, the critical value of  $\chi^2(1) = 3.84$  (Table 3-7, 95 percent,  $df = 1$ ). One degree of freedom is defined since  $(r - 1) = 1$ , and no statistical quantities have been computed for the data.
4. The decision rule:

Reject  $H_0$  if sample  $\chi^2 > 3.84$   
 Accept  $H_0$  otherwise

5. Since it is assumed that  $p = .02$ , this would dictate that in a sample of 950 there would be on the average  $(.02)(950) = 19$  defective items and 931 acceptable items:

| Category       | Observed $O_j$ | Expectation $E_j = 950p_j$ |
|----------------|----------------|----------------------------|
| Acceptable     | 922            | 931                        |
| Not acceptable | 28             | 19                         |
| Total          | 950            | 950                        |

$$\begin{aligned} \text{Sample } \chi^2 &= \frac{(922 - 931)^2}{931} + \frac{(28 - 19)^2}{19} \\ &= 4.35 \text{ with critical } \chi^2 = 3.84 \end{aligned}$$

6. Conclusion. Since the sample value exceeds the critical value, it would be concluded that the process is not in control.

**Example**

**Application** A frequency count of workers was tabulated according to the number of defective items that they produced. An unresolved question is whether the observed distribution is a Poisson distribution. That is, do observed and expected frequencies agree within chance variation?

**Computation**

1. The hypotheses:  
 $H_0$ : there are no significant differences, in number of defective units, between workers  
 $H_1$ : there are significant differences
2. Assume that  $\alpha = .05$ .
3. Test statistic:

| No. of defective units | $O_j$ | $E_j$ |
|------------------------|-------|-------|
| 0                      | 3     | 2.06  |
| 1                      | 7     | 6.64  |
| 2                      | 9     | 10.73 |
| 3                      | 12    | 11.55 |
| 4                      | 9     | 9.33  |
| 5                      | 6     | 6.03  |
| 6                      | 3     | 3.24  |
| 7                      | 2     | 1.50  |
| 8                      | 0     | .60   |
| 9                      | 1     | .22   |
| $\geq 10$              | 0     | .10   |
| Sum                    | 52    | 52    |

The expectation numbers  $E_j$  were computed as follows: For the Poisson distribution,  $\lambda = E(x)$ ; therefore, an estimate of  $\lambda$  is the average number of defective units per worker, i.e.,  $\lambda = (1/52)(0 \times 3 + 1 \times 7 + \dots + 9 \times 1) = 3.23$ . Given this approximation, the probability of no defective units for a worker would be  $(3.23)^0(0!)e^{-3.23} = .0396$ . For the 52 workers, the number of workers producing no defective units would have an expectation  $E = 52(0.0396) = 2.06$ , and so forth.

The sample chi-square value is computed from

$$\begin{aligned} \chi^2 &= \frac{(10 - 8.70)^2}{8.70} + \frac{(9 - 10.73)^2}{10.73} + \dots + \frac{(6 - 5.66)^2}{5.66} \\ &= .522 \end{aligned}$$

4. The critical value of  $\chi^2$  would be based on four degrees of freedom. This corresponds to  $(r - 1) - 1$ , since one statistical quantity  $\lambda$  was computed from the sample and used to derive the expectation numbers.
5. The critical value of  $\chi^2(4) = 9.49$  (Table 3-7) with  $\alpha = .05$ ; therefore, accept  $H_0$ .

**Two-Way Test for Independence for Count Data**

**Nature** When individuals or items are observed and classified according to two different criteria, the resultant counts can be statistically analyzed. For example, a market survey may examine whether a new product is preferred and if it is preferred due to a particular characteristic.

Count data, based on a random selection of individuals or items which are classified according to two different criteria, can be statistically analyzed through the  $\chi^2$  distribution. The purpose of this analysis is to determine whether the respective criteria are dependent. That is, is the product preferred because of a particular characteristic?

**Two-Way Test for Independence for Count Data: Procedure**

**Nomenclature**

1. Each observation is classified according to two categories:
  - a. The first one into 2, 3, . . . , or  $r$  categories
  - b. The second one into 2, 3, . . . , or  $c$  categories
2.  $O_{ij}$  = number of observations (observed counts) in cell  $(i, j)$  with
 
$$i = 1, 2, \dots, r$$

$$j = 1, 2, \dots, c$$

3.  $N$  = total number of observations
4.  $E_{ij}$  = computed number for cell  $(i,j)$  which is an expectation based on the assumption that the two characteristics are independent
5.  $R_i$  = subtotal of counts in row  $i$
6.  $C_j$  = subtotal of counts in column  $j$
7.  $\alpha$  = significance level
8.  $H_0$  = null hypothesis
9.  $H_1$  = alternative hypothesis
10.  $\chi^2$  = critical value of  $\chi^2$  corresponding to the significance level  $\alpha$  and  $(r-1)(c-1)$  df
11. Sample  $\chi^2 = \sum_{i,j} \frac{(O_{ij} - E_{ij})^2}{E_{ij}}$

**Assumptions**

1. The observations represent a sample selected randomly from a large total population.
2. The number of expectation counts  $E_{ij}$  within each cell should be approximately 2 or more for arrays  $3 \times 3$  or larger. If any cell contains a number smaller than 2, appropriate rows or columns should be combined to increase the magnitude of the expectation count. For arrays  $2 \times 2$ , approximately 4 or more are required. If the number is less than 4, the exact Fisher test should be used.

**Test of Hypothesis** Under the null hypothesis, the classification criteria are assumed to be independent, i.e.,

- $H_0$ : the criteria are independent
- $H_1$ : the criteria are not independent

For the stated level of  $\alpha$ ,

- Reject  $H_0$  if sample  $\chi^2 >$  tabled  $\chi^2$
- Accept  $H_0$  otherwise

**Computation for  $E_{ij}$**  Compute  $E_{ij}$  across rows or down columns by using either of the following identities:

$$E_{ij} = C_j \left( \frac{R_i}{N} \right) \text{ across rows}$$

$$E_{ij} = R_i \left( \frac{C_j}{N} \right) \text{ down columns}$$

**Sample  $\chi^2$  Value**

$$\chi^2 = \sum_{i,j} \frac{(O_{ij} - E_{ij})^2}{E_{ij}}$$

In the special case of  $r = 2$  and  $c = 2$ , a more accurate and simplified formula which does not require the direct computation of  $E_{ij}$  can be used:

$$\chi^2 = \frac{[O_{11}O_{22} - O_{12}O_{21} - \frac{1}{2}N]^2 N}{R_1 R_2 C_1 C_2}$$

**Example**

**Application** A market research study was carried out to relate the subjective "feel" of a consumer product to consumer preference. In other words, is the consumer's preference for the product associated with the feel of the product, or is the preference independent of the product feel?

**Procedure**

1. It was of interest to demonstrate whether an association exists between feel and preference; therefore, assume
  - $H_0$ : feel and preference are independent
  - $H_1$ : they are not independent
2. A sample of 200 people was asked to classify the product according to two criteria:
  - a. Liking for this product
  - b. Liking for the feel of the product

|              |     | Like feel |           | $R_i$ |
|--------------|-----|-----------|-----------|-------|
|              |     | Yes       | No        |       |
| Like product | Yes | 114       | 13        | = 127 |
|              | No  | <u>55</u> | <u>18</u> | = 73  |
| $C_j$        |     | 169       | 31        | 200   |

3. Select  $\alpha = .05$ ; therefore, with  $(r-1)(c-1) = 1$  df, the critical value of  $\chi^2$  is 3.84 (Table 3-7, 95 percent).
4. The decision rule:
  - Accept  $H_0$  if sample  $\chi^2 < 3.84$
  - Reject  $H_0$  otherwise

5. The sample value of  $\chi^2$  by using the special formula is

$$\text{Sample } \chi^2 = \frac{[114 \times 18 - 13 \times 55 - 100]^2 200}{(169)(31)(127)(73)} = 6.30$$

6. Since the sample  $\chi^2$  of 6.30 > tabled  $\chi^2$  of 3.84, reject  $H_0$  and accept  $H_1$ . The relative proportionality of  $E_{11} = 169(127/200) = 107.3$  to the observed 114 compared with  $E_{22} = 31(73/200) = 11.3$  to the observed 18 suggests that when the consumer likes the feel, the consumer tends to like the product, and conversely for not liking the feel. The proportions  $169/200 = 84.5$  percent and  $127/200 = 63.5$  percent suggest further that there are other attributes of the product which tend to nullify the beneficial feel of the product.

**LEAST SQUARES**

When experimental data is to be fit with a mathematical model, it is necessary to allow for the fact that the data has errors. The engineer is interested in finding the parameters in the model as well as the uncertainty in their determination. In the simplest case, the model is a linear equation with only two parameters, and they are found by a least-squares minimization of the errors in fitting the data. Multiple regression is just linear least squares applied with more terms. Non-linear regression allows the parameters of the model to enter in a non-linear fashion. See Press et al. (1986); for a description of maximum likelihood as it applies to both linear and nonlinear least squares.

In a least squares parameter estimation, it is desired to find parameters that minimize the sum of squares of the deviation between the experimental data and the theoretical equation.

$$\chi^2 = \sum_{i=1}^N [y_i - y(x_i; a_1, a_2, \dots, a_M)]^2$$

where  $y_i$  is the  $i$ th experimental data point for the value  $x_i$ ,  $y(x_i; a_1, a_2, \dots, a_M)$  is the theoretical equation at  $x_i$ , and the parameters  $\{a_1, a_2, \dots, a_M\}$  are to be determined to minimize  $\chi^2$ . This will also minimize the variance of the curve fit

$$\sigma^2 = \sum_{i=1}^N \frac{[y_i - y(x_i; a_1, a_2, \dots, a_M)]^2}{N}$$

**Linear Least Squares** When the model is a straight line, one is minimizing

$$\chi^2 = \sum_{i=1}^N (y_i - a - bx_i)^2$$

The linear correlation coefficient  $r$  is defined by

$$r = \frac{\sum_{i=1}^N (x_i - \bar{x})(y_i - \bar{y})}{\sqrt{\sum_{i=1}^N (x_i - \bar{x})^2} \sqrt{\sum_{i=1}^N (y_i - \bar{y})^2}}$$

and

$$\chi^2 = (1 - r^2) \sum_{i=1}^N (y_i - \bar{y})^2$$

where  $\bar{y}$  is the average of the  $y_i$  values. Values of  $r$  near 1 indicate a positive correlation;  $r$  near -1 means a negative correlation, and  $r$  near 0 means no correlation. These parameters are easily found by using standard programs, such as Microsoft Excel.

**Example**

**Application.** Brenner (*Magnetic Method for Measuring the Thickness of Non-magnetic Coatings on Iron and Steel*, National Bureau of Standards, RP1081, March 1938) suggests an alternative way of measuring the thickness of nonmagnetic coatings of galvanized zinc on iron and steel. This procedure is based on a nondestructive magnetic method as a substitute for the standard

destructive stripping method. A random sample of 11 pieces was selected and measured by both methods.

**Nomenclature.** The calibration between the magnetic and the stripping methods can be determined through the model

$$y = a + bx + \epsilon$$

where  $x$  = strip-method determination

$y$  = magnetic-method determination

**Sample data**

| Thickness, 10 <sup>-5</sup> in |                         |
|--------------------------------|-------------------------|
| Stripping method,<br>$x$       | Magnetic method,<br>$y$ |
| 104                            | 85                      |
| 114                            | 115                     |
| 116                            | 105                     |
| 129                            | 127                     |
| 132                            | 120                     |
| 139                            | 121                     |
| 174                            | 155                     |
| 312                            | 250                     |
| 338                            | 310                     |
| 465                            | 443                     |
| 720                            | 630                     |

This example is solved by using Microsoft Excel. Put the data into columns A and B as shown, using rows 1 through 11. Then the commands

SLOPE(B1:B11, A1:A11), INTERCEPT(B1:B11, A1:A11), RSQ(B1:B11, A1:A11)

give the slope  $b$ , the intercept  $a$ , and the value of  $r^2$ . Here they are 3.20, 0.884, and 0.9928, respectively, so that  $r = 0.9964$ . By choosing Insert/Chart and Scatter Plot, the data are plotted. Once that is done, place the cursor on a data point and right-click; choose Format trendline with options selected to display the equation and  $r^2$ , and you get Fig. 3-66. On the Macintosh, use CTRL-click.

**Polynomial Regression** In polynomial regression, one expands the function in a polynomial in  $x$ .

$$y(x) = \sum_{j=1}^M a_j x^{j-1}$$

**Example**

**Application.** Merriman ("The Method of Least Squares Applied to a Hydraulic Problem," *J. Franklin Inst.*, 233-241, October 1877) reported on a

study of stream velocity as a function of relative depth of the stream.

**Sample data**

| Depth <sup>a</sup> | Velocity, $y$ , ft/s |
|--------------------|----------------------|
| 0                  | 3.1950               |
| .1                 | 3.2299               |
| .2                 | 3.2532               |
| .3                 | 3.2611               |
| .4                 | 3.2516               |
| .5                 | 3.2282               |
| .6                 | 3.1807               |
| .7                 | 3.1266               |
| .8                 | 3.0594               |
| .9                 | 2.9759               |

<sup>a</sup>As a fraction of total depth.

The model is taken as a quadratic function of position:

$$\text{Velocity} = a + bx + cx^2$$

The parameters are easily determined by using computer software. In Microsoft Excel, the data are put into columns A and B and the graph is created as for a linear curve fit. This time, though, when adding the trendline, choose the polynomial icon and use 2 (which gives powers up to and including  $x^2$ ). The result is

$$\text{Velocity} = 3.195 + 0.4425x - 0.7653x^2$$

The value of  $r^2$  is .9993.

**Multiple Regression** In multiple regression, any set of functions can be used, not just polynomials, such as

$$y(x) = \sum_{j=1}^M a_j f_j(x)$$

where the set of functions  $\{f_j(x)\}$  is known and specified. Note that the unknown parameters  $\{a_j\}$  enter the equation linearly. In this case, the spreadsheet can be expanded to have a column for  $x$  and then successive columns for  $f_j(x)$ . In Microsoft Excel, you choose Regression under Tools/Data Analysis, and complete the form. In addition to the actual correlation, you get the expected variance of the unknowns, which allows you to assess how accurately they were determined. In the example above, by creating a column for  $x$  and  $x^2$ , one obtains an intercept of 3.195 with a standard error of .0039,  $b = .4416$  with a standard error of .018, and  $c = -.7645$  with a standard error of .018.

**Nonlinear Least Squares** There are no analytic methods for determining the most appropriate model for a particular set of data.

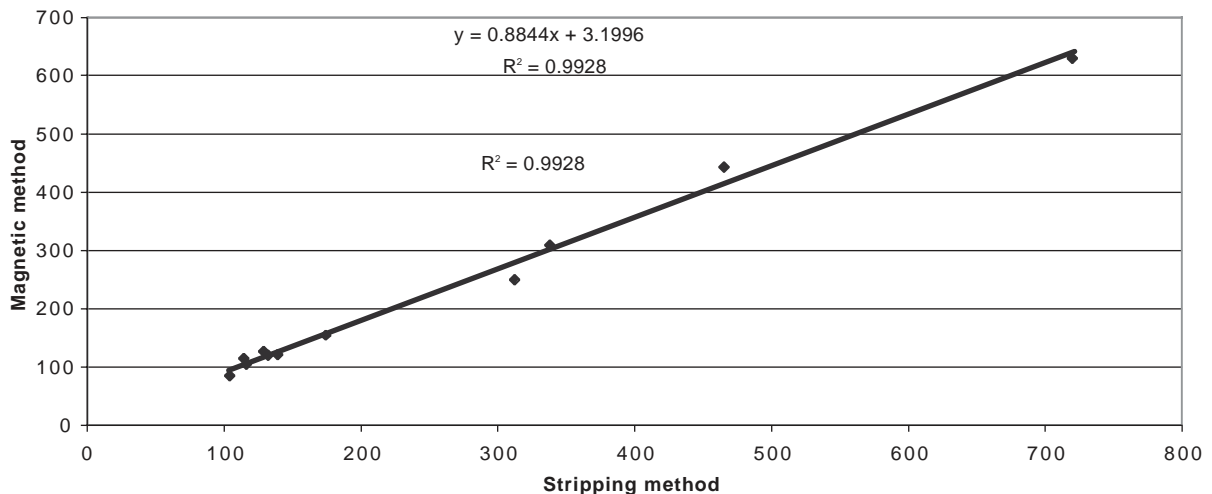

FIG. 3-66 Plot of data and correlating line.

In many cases, however, the engineer has some basis for a model. If the parameters occur in a nonlinear fashion, then the analysis becomes more difficult. For example, in relating the temperature to the elapsed time of a fluid cooling in the atmosphere, a model that has an asymptotic property would be the appropriate model ( $\text{temp} = a + b \exp(-c \text{ time})$ ), where  $a$  represents the asymptotic temperature corresponding to  $t \rightarrow \infty$ . In this case, the parameter  $c$  appears nonlinearly. The usual practice is to concentrate on model development and computation rather than on statistical aspects. In general, nonlinear regression should be applied only to problems in which there is a well-defined, clear association between the two variables; therefore, a test of hypothesis on the significance of the fit would be somewhat ludicrous. In addition, the generalization of the theory for the associate confidence intervals for nonlinear coefficients is not well developed.

**Example**

*Application.* Data were collected on the cooling of water in the atmosphere as a function of time.

*Sample data*

| Time $x$ | Temperature $y$ |
|----------|-----------------|
| 0        | 92.0            |
| 1        | 85.5            |
| 2        | 79.5            |
| 3        | 74.5            |
| 5        | 67.0            |
| 7        | 60.5            |
| 10       | 53.5            |
| 15       | 45.0            |
| 20       | 39.5            |

*Model.* MATLAB can be used to find the best fit of the data to the formula  $y = a + be^{cx}$ :  $a = 33.54$ ,  $b = 57.89$ ,  $c = 0.11$ . The value of  $\chi^2$  is 1.83. Using an alternative form,  $y = a + b/(c + x)$ , gives  $a = 9.872$ ,  $b = 925.7$ ,  $c = 11.27$ , and  $\chi = 0.19$ . Since this model had a smaller value of  $\chi^2$  it might be the chosen one, but it is only a fit of the specified data and may not be generalized beyond that. Both forms give equivalent plots.

**ERROR ANALYSIS OF EXPERIMENTS**

Consider the problem of assessing the accuracy of a series of measurements. If measurements are for independent, identically distributed observations, then the errors are independent and uncorrelated. Then  $\bar{y}$ , the experimentally determined mean, varies about  $E(y)$ , the true mean, with variance  $\sigma^2/n$ , where  $n$  is the number of observations in  $\bar{y}$ . Thus, if one measures something several times today, and each day, and the measurements have the same distribution, then the variance of the means decreases with the number of samples in each day's measurement,  $n$ . Of course, other factors (weather, weekends) may make the observations on different days *not* distributed identically.

Consider next the problem of estimating the error in a variable that cannot be measured directly but must be calculated based on results of other measurements. Suppose the computed value  $Y$  is a linear combination of the measured variables  $\{y_i\}$ ,  $Y = \alpha_1 y_1 + \alpha_2 y_2 + \dots$ . Let the random variables  $y_1, y_2, \dots$  have means  $E(y_1), E(y_2), \dots$  and variances  $\sigma^2(y_1), \sigma^2(y_2), \dots$ . The variable  $Y$  has mean

$$E(Y) = \alpha_1 E(y_1) + \alpha_2 E(y_2) + \dots$$

and variance (Cropley, 1978)

$$\sigma^2(Y) = \sum_{i=1}^n \alpha_i^2 \sigma^2(y_i) + 2 \sum_{i=1}^n \sum_{j=i+1}^n \alpha_i \alpha_j \text{Cov}(y_i, y_j)$$

If the variables are uncorrelated and have the same variance, then

$$\sigma^2(Y) = \left( \sum_{i=1}^n \alpha_i^2 \right) \sigma^2$$

Next suppose the model relating  $Y$  to  $\{y_i\}$  is nonlinear, but the errors are small and independent of one another. Then a change in  $Y$  is related to changes in  $y_i$  by

$$dY = \frac{\partial Y}{\partial y_1} dy_1 + \frac{\partial Y}{\partial y_2} dy_2 + \dots$$

If the changes are indeed small, then the partial derivatives are constant among all the samples. Then the expected value of the change,  $E(dY)$ , is zero. The variances are given by the following equation (Baird, 1995; Box et al., 2005):

$$\sigma^2(dY) = \sum_{i=1}^N \left( \frac{\partial Y}{\partial y_i} \right)^2 \sigma_i^2$$

Thus, the variance of the desired quantity  $Y$  can be found. This gives an independent estimate of the errors in measuring the quantity  $Y$  from the errors in measuring each variable it depends upon.

**Example** Suppose one wants to measure the thermal conductivity of a solid ( $k$ ). To do this, one needs to measure the heat flux ( $q$ ), the thickness of the sample ( $d$ ), and the temperature difference across the sample ( $\Delta T$ ). Each measurement has some error. The heat flux ( $q$ ) may be the rate of electrical heat input ( $\dot{Q}$ ) divided by the area ( $A$ ), and both quantities are measured to some tolerance. The thickness of the sample is measured with some accuracy, and the temperatures are probably measured with a thermocouple to some accuracy. These measurements are combined, however, to obtain the thermal conductivity, and it is desired to know the error in the thermal conductivity. The formula is

$$k = \frac{d}{\Delta T} \dot{Q}$$

The variance in the thermal conductivity is then

$$\sigma_k^2 = \left( \frac{k}{d} \right)^2 \sigma_d^2 + \left( \frac{k}{\dot{Q}} \right)^2 \sigma_{\dot{Q}}^2 + \left( \frac{k}{A} \right)^2 \sigma_A^2 + \left( \frac{k}{\Delta T} \right)^2 \sigma_{\Delta T}^2$$

**FACTORIAL DESIGN OF EXPERIMENTS AND ANALYSIS OF VARIANCE**

Statistically designed experiments consider, of course, the effect of primary variables, but they also consider the effect of extraneous variables and the interactions between variables, and they include a measure of the random error. Primary variables are those whose effect you wish to determine. These variables can be quantitative or qualitative. The quantitative variables are ones you may fit to a model in order to determine the model parameters (see the section "Least Squares"). Qualitative variables are ones you wish to know the effect of, but you do not try to quantify that effect other than to assign possible errors or magnitudes. Qualitative variables can be further subdivided into Type I variables, whose effect you wish to determine directly, and Type II variables, which contribute to the performance variability and whose effect you wish to average out. For example, if you are studying the effect of several catalysts on yield in a chemical reactor, each different type of catalyst would be a Type I variable because you would like to know the effect of each. However, each time the catalyst is prepared, the results are slightly different due to random variations; thus, you may have several batches of what purports to be the same catalyst. The variability between batches is a Type II variable. Since the ultimate use will require using different batches, you would like to know the overall effect including that variation, since knowing precisely the results from one batch of one catalyst might not be representative of the results obtained from all batches of the same catalyst. A randomized block design, incomplete block design, or Latin square design (Box et al., *ibid.*), for example, all keep the effect of experimental error in the blocked variables from influencing the effect of the primary variables. Other uncontrolled variables are accounted for by introducing randomization in parts of the experimental design. To study all variables and their interaction requires a factorial design, involving all possible combinations of each variable, or a fractional factorial design, involving only a selected set. Statistical techniques are then used to determine which are the important variables, what are the important interactions, and what the error is in estimating these effects. The discussion here is only a brief overview of the excellent book by Box et al. (2005).

Suppose we have two methods of preparing some product and we wish to see which treatment is best. When there are only two treatments, then the sampling analysis discussed in the section "Two-Population Test of Hypothesis for Means" can be used to deduce if the means of the two treatments differ significantly. When there are more treatments, the analysis is more detailed. Suppose the experimental results are arranged

as shown in the table: several measurements for each treatment. The goal is to see if the treatments differ significantly from each other; that is, whether their means are different when the samples have the same variance. The hypothesis is that the treatments are all the same, and the null hypothesis is that they are different. The statistical validity of the hypothesis is determined by an analysis of variance.

**Estimating the Effect of Four Treatments**

|                   | Treatment |   |   |   |
|-------------------|-----------|---|---|---|
|                   | 1         | 2 | 3 | 4 |
| —                 | —         | — | — | — |
| —                 | —         | — | — | — |
| —                 | —         | — | — | — |
| Treatment average | —         | — | — | — |
| Grand average     | —         | — | — | — |

The data for  $k = 4$  treatments is arranged in the table. For each treatment, there are  $n_t$  experiments and the outcome of the  $i$ th experiment with treatment  $t$  is called  $y_{ti}$ . Compute the treatment average

$$\bar{y}_t = \frac{\sum_{i=1}^{n_t} y_{ti}}{n_t}$$

Also compute the grand average

$$\bar{y} = \frac{\sum_{t=1}^k n_t \bar{y}_t}{N}, \quad N = \sum_{t=1}^k n_t$$

Next compute the sum of squares of deviations from the average within the  $t$ th treatment

$$S_t = \sum_{i=1}^{n_t} (y_{ti} - \bar{y}_t)^2$$

Since each treatment has  $n_t$  experiments, the number of degrees of freedom is  $n_t - 1$ . Then the sample variances are

$$s_t^2 = \frac{S_t}{n_t - 1}$$

The within-treatment sum of squares is

$$S_R = \sum_{t=1}^k S_t$$

and the within-treatment sample variance is

$$s_R^2 = \frac{S_R}{N - k}$$

Now, if there is no difference between treatments, a second estimate of  $\sigma^2$  could be obtained by calculating the variation of the treatment averages about the grand average. Thus compute the between-treatment mean square

$$s_T^2 = \frac{S_T}{k - 1}, \quad S_T = \sum_{t=1}^k n_t (\bar{y}_t - \bar{y})^2$$

Basically the test for whether the hypothesis is true or not hinges on a comparison of the within-treatment estimate  $s_R^2$  (with  $v_R = N - k$  degrees of freedom) with the between-treatment estimate  $s_T^2$  (with  $v_T = k - 1$  degrees of freedom). The test is made based on the  $F$  distribution for  $v_R$  and  $v_T$  degrees of freedom (Table 3-8).

Next consider the case that uses randomized blocking to eliminate the effect of some variable whose effect is of no interest, such as the batch-to-batch variation of the catalysts in the chemical reactor example. Suppose there are  $k$  treatments and  $n$  experiments in each treatment. The results from  $nk$  experiments can be arranged as shown in the block design table; within each block, the various treatments are applied in a random order. Compute the block average, the treatment average, as well as the grand average as before.

**Block Design with Four Treatments and Five Blocks**

| Treatment | 1 | 2 | 3 | 4 | Block average |
|-----------|---|---|---|---|---------------|
| Block 1   | — | — | — | — | —             |
| Block 2   | — | — | — | — | —             |
| Block 3   | — | — | — | — | —             |
| Block 4   | — | — | — | — | —             |
| Block 5   | — | — | — | — | —             |

The following quantities are needed for the analysis of variance table.

| Name       | Formula  | dof              |
|------------|--|------------------|
| average    | $S_A = nk\bar{y}^2$  | 1                |
| blocks     | $S_B = k \sum_{i=1}^n (\bar{y}_i - \bar{y})^2$                                     | $n - 1$          |
| treatments | $S_T = n \sum_{t=1}^k (\bar{y}_t - \bar{y})^2$                                     | $k - 1$          |
| residuals  | $S_R = \sum_{t=1}^k \sum_{i=1}^{n_t} (y_{ti} - \bar{y}_t - \bar{y}_t + \bar{y})^2$ | $(n - 1)(k - 1)$ |
| total      | $S = \sum_{t=1}^k \sum_{i=1}^{n_t} y_{ti}^2$                                       | $N = nk$         |

The key test is again a statistical one, based on the value of

$$\frac{s_T^2}{s_R^2}, \quad s_T^2 = \frac{S_T}{k - 1}, \quad s_R^2 = \frac{S_R}{(n - 1)(k - 1)}$$

and the  $F$  distribution for  $v_R$  and  $v_T$  degrees of freedom (Table 3-8). The assumption behind the analysis is that the variations are linear. See Box et al. (2005). There are ways to test this assumption as well as transformations to make if it is not true. Box et al. also give an excellent example of how the observations are broken down into a grand average, a block deviation, a treatment deviation, and a residual. For two-way factorial design in which the second variable is a real one rather than one you would like to block out, see Box et al.

To measure the effects of variables on a single outcome a factorial design is appropriate. In a two-level factorial design, each variable is considered at two levels only, a high and low value, often designated as a + and -. The two-level factorial design is useful for indicating trends, showing interactions, and it is also the basis for a fractional factorial design. As an example, consider a  $2^3$  factorial design with 3 variables and 2 levels for each. The experiments are indicated in the factorial design table.

**Two-Level Factorial Design with Three Variables**

| Run | Variable |   |   |
|-----|----------|---|---|
|     | 1        | 2 | 3 |
| 1   | -        | - | - |
| 2   | +        | - | - |
| 3   | -        | + | - |
| 4   | +        | + | - |
| 5   | -        | - | + |
| 6   | +        | - | + |
| 7   | -        | + | + |
| 8   | +        | + | + |

The main effects are calculated by calculating the difference between results from all high values of a variable and all low values of a variable; the result is divided by the number of experiments at each level. For example, for the first variable:

$$\text{Effect of variable 1} = \frac{(y_2 + y_4 + y_6 + y_8) - (y_1 + y_3 + y_5 + y_7)}{4}$$

Note that all observations are being used to supply information on each of the main effects and each effect is determined with the precision of a fourfold replicated difference. The advantage of a one-at-a-time experiment is the gain in precision if the variables are additive and the measure of nonadditivity if it occurs (Box et al., 2005).

Interaction effects between variables 1 and 2 are obtained by calculating the difference between the results obtained with the high and low value of 1 at the low value of 2 compared with the results obtained

with the high and low value 1 at the high value of 2. The 12-interaction is

$$12\text{-interaction} = \frac{[(y_4 - y_3 + y_8 - y_7) - (y_2 - y_1 + y_6 - y_5)]}{2}$$

The key step is to determine the errors associated with the effect of each variable and each interaction so that the significance can be determined. Thus, standard errors need to be assigned. This can be done by repeating the experiments, but it can also be done by using higher-order interactions (such as 123 interactions in a 2<sup>4</sup> factorial design). These are assumed negligible in their effect on the mean but can be used to estimate the standard error. Then, calculated

effects that are large compared with the standard error are considered important, while those that are small compared with the standard error are considered to be due to random variations and are unimportant.

In a fractional factorial design one does only part of the possible experiments. When there are *k* variables, a factorial design requires 2<sup>*k*</sup> experiments. When *k* is large, the number of experiments can be large; for *k* = 5, 2<sup>5</sup> = 32. For a *k* this large, Box et al. (2005) do a fractional factorial design. In the fractional factorial design with *k* = 5, only 16 experiments are done. Cropley (1978) gives an example of how to combine heuristics and statistical arguments in application to kinetics mechanisms in chemical engineering.

### DIMENSIONAL ANALYSIS

Dimensional analysis allows the engineer to reduce the number of variables that must be considered to model experiments or correlate data. Consider a simple example in which two variables *F*<sub>1</sub> and *F*<sub>2</sub> have the units of force and two additional variables *L*<sub>1</sub> and *L*<sub>2</sub> have the units of length. Rather than having to deduce the relation of one variable on the other three, *F*<sub>1</sub> = fn (*F*<sub>2</sub>, *L*<sub>1</sub>, *L*<sub>2</sub>), dimensional analysis can be used to show that the relation must be of the form *F*<sub>1</sub>/*F*<sub>2</sub> = fn (*L*<sub>1</sub>/*L*<sub>2</sub>). Thus considerable experimentation is saved. Historically, dimensional analysis can be done using the Rayleigh method or the Buckingham pi method. This brief discussion is equivalent to the Buckingham pi method but uses concepts from linear algebra; see Amundson, N. R., *Mathematical Methods in Chemical Engineering*, Prentice-Hall, Englewood Cliffs, N.J. (1966), p. 54, for further information.

The general problem is posed as finding the minimum number of variables necessary to define the relationship between *n* variables. Let {*Q*<sub>*i*</sub>} represent a set of fundamental units, like length, time, force, and so on. Let [*P*<sub>*i*</sub>] represent the dimensions of a physical quantity *P*<sub>*i*</sub>; there are *n* physical quantities. Then form the matrix α<sub>*ij*</sub>

|                              |                           |                           |     |                                  |
|------------------------------|---------------------------|---------------------------|-----|----------------------------------|
|                              | [ <i>P</i> <sub>1</sub> ] | [ <i>P</i> <sub>2</sub> ] | ... | [ <i>P</i> <sub><i>n</i></sub> ] |
| <i>Q</i> <sub>1</sub>        | α <sub>11</sub>           | α <sub>12</sub>           | ... | α <sub>1<i>n</i></sub>           |
| <i>Q</i> <sub>2</sub>        | α <sub>21</sub>           | α <sub>22</sub>           | ... | α <sub>2<i>n</i></sub>           |
| ...                          |                           |                           |     |                                  |
| <i>Q</i> <sub><i>m</i></sub> | α <sub><i>m</i>1</sub>    | α <sub><i>m</i>2</sub>    | ... | α <sub><i>m</i><i>n</i></sub>    |

in which the entries are the number of times each fundamental unit appears in the dimensions [*P*<sub>*i*</sub>]. The dimensions can then be expressed as follows.

$$[P_i] = Q_1^{\alpha_{i1}} Q_2^{\alpha_{i2}} \dots Q_m^{\alpha_{im}}$$

Let *m* be the rank of the α matrix. Then *p* = *n* - *m* is the number of dimensionless groups that can be formed. One can choose *m* variables {*P*<sub>*i*</sub>} to be the basis and express the other *p* variables in terms of them, giving *p* dimensionless quantities.

**Example: Buckingham Pi Method—Heat-Transfer Film Coefficient** It is desired to determine a complete set of dimensionless groups with which to correlate experimental data on the film coefficient of heat transfer between the walls of a straight conduit with circular cross section and a fluid flowing in that conduit. The variables and the dimensional constant believed to be involved and their dimensions in the engineering system are given below:

- Film coefficient = *h* = (*F*/*LθT*)
- Conduit internal diameter = *D* = (*L*)
- Fluid linear velocity = *V* = (*L*/*θ*)
- Fluid density = ρ = (*M*/*L*<sup>3</sup>)
- Fluid absolute viscosity = μ = (*M*/*Lθ*)
- Fluid thermal conductivity = *k* = (*F*/*θT*)
- Fluid specific heat = *c<sub>p</sub>* = (*FL*/*MT*)
- Dimensional constant = *g<sub>c</sub>* = (*ML*/*Fθ*<sup>2</sup>)

The matrix α in this case is as follows.

|          |                                  |          |          |    |    |          |                      |                      |
|----------|----------------------------------|----------|----------|----|----|----------|----------------------|----------------------|
|          | [ <i>P</i> <sub><i>i</i></sub> ] |          |          |    |    |          |                      |                      |
|          | <i>h</i>                         | <i>D</i> | <i>V</i> | ρ  | μ  | <i>k</i> | <i>C<sub>p</sub></i> | <i>g<sub>c</sub></i> |
| <i>F</i> | 1                                | 0        | 0        | 0  | 0  | 1        | 1                    | -1                   |
| <i>M</i> | 0                                | 0        | 0        | 1  | 1  | 0        | -1                   | 1                    |
| <i>L</i> | -1                               | 1        | 1        | -3 | -1 | 0        | 1                    | 1                    |
| θ        | -1                               | 0        | -1       | 0  | -1 | -1       | 0                    | -2                   |
| <i>T</i> | -1                               | 0        | 0        | 0  | 0  | -1       | -1                   | 0                    |

Here *m* ≤ 5, *n* = 8, *p* ≥ 3. Choose *D*, *V*, μ, *k*, and *g<sub>c</sub>* as the primary variables. By examining the 5 × 5 matrix associated with those variables, we can see that its determinant is not zero, so the rank of the matrix is *m* = 5; thus, *p* = 3. These variables are thus a possible basis set. The dimensions of the other three variables *h*, ρ, and *C<sub>p</sub>* must be defined in terms of the primary variables. This can be done by inspection, although linear algebra can be used, too.

$$[h] = D^{-1}k^{-1}; \text{ thus } \frac{h}{D^{-1}k^{-1}} = \frac{hD}{k} \text{ is a dimensionless group}$$

$$[\rho] = \mu^1 V^{-1} D^{-1}; \text{ thus } \frac{\rho}{\mu^1 V^{-1} D^{-1}} = \frac{\rho VD}{\mu} \text{ is a dimensionless group}$$

$$[C_p] = k^{-1} \mu^{-1}; \text{ thus } \frac{C_p}{k^{-1} \mu^{-1}} = \frac{C_p \mu}{k} \text{ is a dimensionless group}$$

Thus, the dimensionless groups are

$$\frac{[P_i]}{Q_1^{\alpha_{i1}} Q_2^{\alpha_{i2}} \dots Q_m^{\alpha_{im}}}; \frac{hD}{k}, \frac{\rho VD}{\mu}, \frac{C_p \mu}{k}$$

The dimensionless group *hD*/*k* is called the Nusselt number, *N<sub>Nu</sub>*, and the group *C<sub>p</sub>*μ/*k* is the Prandtl number, *N<sub>Pr</sub>*. The group *DVρ*/*μ* is the familiar Reynolds number, *N<sub>Re</sub>*, encountered in fluid-friction problems. These three dimensionless groups are frequently used in heat-transfer-film-coefficient correlations. Functionally, their relation may be expressed as

$$\Phi(N_{Nu}, N_{Pr}, N_{Re}) = 0 \tag{3-121}$$

or as

$$N_{Nu} = \Phi_1(N_{Pr}, N_{Re})$$

**TABLE 3-9 Dimensionless Groups in the Engineering System of Dimensions**

|                                       |                       |  |
|---------------------------------------|-----------------------|--|
| Biot number                           | <i>N<sub>Bi</sub></i> | <i>hL</i> / <i>k</i>   |
| Condensation number                   | <i>N<sub>Co</sub></i> | ( <i>h</i> / <i>k</i> )(μ <sup>2</sup> /ρ <sup>2</sup> <i>g</i> ) <sup>1/3</sup> |
| Number used in condensation of vapors | <i>N<sub>Cv</sub></i> | <i>L</i> <sup>3</sup> ρ <sup>2</sup> <i>g</i> λ/ <i>k</i> μΔ <i>t</i>            |
| Euler number                          | <i>N<sub>Eu</sub></i> | <i>g<sub>c</sub></i> (-Δ <i>p</i> )/ρ <i>V</i> <sup>2</sup>                      |
| Fourier number                        | <i>N<sub>Fo</sub></i> | <i>kθ</i> /ρ <i>cL</i> <sup>2</sup>  |
| Froude number                         | <i>N<sub>Fr</sub></i> | <i>V</i> <sup>2</sup> / <i>Lg</i>  |
| Graetz number                         | <i>N<sub>Gz</sub></i> | <i>wc</i> / <i>kL</i>  |
| Grashof number                        | <i>N<sub>Gr</sub></i> | <i>L</i> <sup>3</sup> ρ <sup>2</sup> β <i>g</i> Δ <i>t</i> /μ <sup>2</sup>       |
| Mach number                           | <i>N<sub>Ma</sub></i> | <i>V</i> / <i>V<sub>a</sub></i>  |
| Nusselt number                        | <i>N<sub>Nu</sub></i> | <i>hD</i> / <i>k</i>   |
| Peclet number                         | <i>N<sub>Pe</sub></i> | <i>DVρc</i> / <i>k</i>   |
| Prandtl number                        | <i>N<sub>Pr</sub></i> | <i>cμ</i> / <i>k</i>   |
| Reynolds number                       | <i>N<sub>Re</sub></i> | <i>DVρ</i> / <i>μ</i>  |
| Schmidt number                        | <i>N<sub>Sc</sub></i> | μ/ρ <i>D<sub>v</sub></i>   |
| Stanton number                        | <i>N<sub>St</sub></i> | <i>h</i> / <i>cVρ</i>  |
| Weber number                          | <i>N<sub>We</sub></i> | <i>LV</i> <sup>2</sup> ρ/σ <i>g<sub>c</sub></i>                                  |

It has been found that these dimensionless groups may be correlated well by an equation of the type

$$hD/k = K(c_p \mu/k)^a (DV\rho/\mu)^b$$

in which  $K$ ,  $a$ , and  $b$  are experimentally determined dimensionless constants. However, any other type of algebraic expression or perhaps simply a graphical relation among these three groups that accurately fits the experimental data would be an equally valid manner of expressing Eq. (3-121).

Naturally, other dimensionless groups might have been obtained in the example by employing a different set of five repeating quantities

that would not form a dimensionless group among themselves. Some of these groups may be found among those presented in Table 3-9. Such a complete set of three dimensionless groups might consist of Stanton, Reynolds, and Prandtl numbers or of Stanton, Peclet, and Prandtl numbers. Also, such a complete set different from that obtained in the preceding example will result from a multiplication of appropriate powers of the Nusselt, Prandtl, and Reynolds numbers. For such a set to be complete, however, it must satisfy the condition that each of the three dimensionless groups be independent of the other two.

## PROCESS SIMULATION

Lewin, *Product and Process Design Principles: Synthesis, Analysis, and Evaluation*, 2d ed., Wiley, New York (2004).

### CLASSIFICATION

*Process simulation* refers to the activity in which mathematical systems of chemical processes and refineries are modeled with equations, usually on the computer. The usual distinction must be made between steady-state models and transient models, following the ideas presented in the introduction to this section. In a chemical process, of course, the process is nearly always in a transient mode, at some level of precision, but when the time-dependent fluctuations are below some value, a steady-state model can be formulated. This subsection presents briefly the ideas behind steady-state process simulation (also called flowsheeting), which are embodied in commercial codes. The transient simulations are important for designing the start-up of plants and are especially useful for the operation of chemical plants.

### THERMODYNAMICS

The most important aspect of the simulation is that the thermodynamic data of the chemicals be modeled correctly. It is necessary to decide what equation of state to use for the vapor phase (ideal gas, Redlich-Kwong-Soave, Peng-Robinson, etc.) and what model to use for liquid activity coefficients [ideal solutions, solubility parameters, Wilson equation, nonrandom two liquid (NRTL), UNIFAC, etc.]. See Sec. 4, “Thermodynamics.” It is necessary to consider mixtures of chemicals, and the interaction parameters must be predictable. The best case is to determine them from data, and the next-best case is to use correlations based on the molecular weight, structure, and normal boiling point. To validate the model, the computer results of vapor-liquid equilibria could be checked against experimental data to ensure their validity before the data are used in more complicated computer calculations.

### PROCESS MODULES OR BLOCKS

At the first level of detail, it is not necessary to know the internal parameters for all the units, since what is desired is just the overall performance. For example, in a heat exchanger design, it suffices to know the heat duty, the total area, and the temperatures of the output streams; the details such as the percentage baffle cut, tube layout, or baffle spacing can be specified later when the details of the proposed plant are better defined. It is important to realize the level of detail modeled by a commercial computer program. For example, a chemical reactor could be modeled as an equilibrium reactor, in which the input stream is brought to a new temperature and pressure and the

output stream is in chemical equilibrium at those new conditions. Or, it may suffice to simply specify the conversion, and the computer program will calculate the outlet compositions. In these cases, the model equations are algebraic ones, and you do not learn the volume of the reactor. A more complicated reactor might be a stirred tank reactor, and then you would have to specify kinetic information so that the simulation can be made, and one output would be either the volume of the reactor or the conversion possible in a volume you specify. Such models are also composed of sets of algebraic equations. A plug flow reactor is modeled as a set of ordinary differential equations as initial-value problems, and the computer program must use numerical methods to integrate them. See “Numerical Solution of Ordinary Differential Equations as Initial Value Problems.” Kinetic information must be specified, and one learns the conversion possible in a given reactor volume, or, in some cases, the volume reactor that will achieve a given conversion. The simulation engineer determines what a reactor of a given volume will do for the specified kinetics and reactor volume. The design engineer, though, wants to achieve a certain result and wants to know the volume necessary. Simulation packages are best suited for the simulation engineer, and the design engineer must vary specifications to achieve the desired output.

Distillation simulations can be based on shortcut methods, using correlations based on experience, but more rigorous methods involve solving for the vapor-liquid equilibrium on each tray. The shortcut method uses relatively simple equations, and the rigorous method requires solution of huge sets of nonlinear equations. The computation time of the latter is significant, but the rigorous method may be necessary when the chemicals you wish to distill are not well represented in the correlations. Then the designer must specify the number of trays and determine the separation that is possible. This, of course, is not what he or she wants: the number of trays needed to achieve a specified objective. Thus, again, some adjustment of parameters is necessary in a design situation.

Absorption columns can be modeled in a plate-to-plate fashion (even if it is a packed bed) or as a packed bed. The former model is a set of nonlinear algebraic equations, and the latter model is an ordinary differential equation. Since streams enter at both ends, the differential equation is a two-point boundary value problem, and numerical methods are used (see “Numerical Solution of Ordinary Differential Equations as Initial-Value Problems”).

If one wants to model a process unit that has significant flow variation, and possibly some concentration distributions as well, one can consider using computational fluid dynamics (CFD) to do so. These calculations are very time-consuming, though, so that they are often left until the mechanical design of the unit. The exception would occur when the flow variation and concentration distribution had a significant effect on the output of the unit so that mass and energy balances couldn't be made without it.

The process units are described in greater detail in other sections of the Handbook. In each case, parameters of the unit are specified (size, temperature, pressure, area, and so forth). In addition, in a computer simulation, the computer program must be able to take any input to the unit and calculate the output for those parameters. Since the entire calculation is done iteratively, there is no assurance that the

FIG. 3-67 Prototype flowsheet.

input stream is a “reasonable” one, so that the computer codes must be written to give some sort of output even when the input stream is unreasonable. This difficulty makes the iterative process even more complicated.

### PROCESS TOPOLOGY

A chemical process usually consists of a series of units, such as distillation towers, reactors, and so forth (see Fig. 3-67). If the feed to the process is known and the operating parameters of the units are specified by the user, then one can begin with the first unit, take the process input, calculate the unit output, carry that output to the input of the next unit, and continue the process. However, if the process involves a recycle stream, as nearly all chemical processes do, then when the calculation is begun, it is discovered that the recycle stream is unknown. This situation leads to an iterative process: the flow rates, temperature, and pressure of the unknown recycle stream are guessed, and the calculations proceed as before. When one reaches the end of the process, where the recycle stream is formed to return to the first unit, it is necessary to check to see if the recycle stream is the same as assumed. If not, an iterative procedure must be used to cause convergence. Possible techniques are described in “Numerical Solutions of Nonlinear Equations in One Variable” and “Numerical Solution of Simultaneous Equations.” The direct method (or successive substitution method) just involves calculating around the process over and over. The Wegstein method accelerates convergence for a single variable, and Broyden’s method does the same for multiple variables. The Newton method can be used provided there is some way to calculate the derivatives (possibly by using a numerical derivative). Optimization methods can also be used (see “Optimization” in this section). In the description given here, the recycle stream is called the tear stream: this is the stream that must be guessed to begin the calculation. When there are multiple recycle streams, convergence is even more difficult, since more guesses are necessary, and what happens in one recycle stream may cause difficulties for the guesses in other recycle streams. See Seader (1985) and Mah (1990).

It is sometimes desired to control some stream by varying an operating parameter. For example, in a reaction/separation system, if there is an impurity that must be purged, a common objective is to set the purge fraction so that the impurity concentration into the reactor is kept at some moderate value. Commercial packages contain procedures for

doing this using what are often called control blocks. However, this can also make the solution more difficult to find.

An alternative method of solving the equations is to solve them as simultaneous equations. In that case, one can specify the design variables and the desired specifications and let the computer figure out the process parameters that will achieve those objectives. It is possible to overspecify the system or to give impossible conditions. However, the biggest drawback to this method of simulation is that large sets (tens of thousands) of nonlinear algebraic equations must be solved simultaneously. As computers become faster, this is less of an impediment, provided efficient software is available.

Dynamic simulations are also possible, and these require solving differential equations, sometimes with algebraic constraints. If some parts of the process change extremely quickly when there is a disturbance, that part of the process may be modeled in the steady state for the disturbance at any instant. Such situations are called stiff, and the methods for them are discussed in “Numerical Solution of Ordinary Differential Equations as Initial-Value Problems.” It must be realized, though, that a dynamic calculation can also be time-consuming, and sometimes the allowable units are lumped-parameter models that are simplifications of the equations used for the steady-state analysis. Thus, as always, the assumptions need to be examined critically before accepting the computer results.

### COMMERCIAL PACKAGES

Computer programs are provided by many companies, and the models range from empirical models to deterministic models. For example, if one wanted to know the pressure drop in a piping network, one would normally use a correlation for friction factor as a function of Reynolds number to calculate the pressure drop in each segment. A sophisticated turbulence model of fluid flow is not needed in that case. As computers become faster, however, more and more models are deterministic. Since the commercial codes have been used by many customers, the data in them have been verified, but possibly not for the case you want to solve. Thus, you must test the thermodynamics correlations carefully. In 2005, there were a number of computer codes, but the company names change constantly. Here are a few of them for process simulation: Aspen Tech (Aspen Plus), Chemstations (CHEMCAD), Honeywell (UniSim Design), ProSim (ProSimPlus), and SimSci-Esseor (Pro II). The CAPE-OPEN project is working to make details as transferable as possible.

| $f_i^s$            | Fugacity of species $i$ in solution  | kPa                               | psi                               | $Z$                | Compressibility factor                               | Dimensionless                            | Dimensionless                                     |
| $\bar{G}$          | Molar (or unit-mass) Gibbs energy  | J/mol [J/kg]                      | Btu/(lb-mol)<br>[Btu/lbm]         | $z$                | Elevation above a datum level                        | m  | ft  |
| $g$                | Acceleration of gravity  | m/s <sup>2</sup>                  | ft/s <sup>2</sup>                 | Superscripts       |  |  |   |
| $\frac{g}{g}$      | $\equiv C_p^*/RT$  | Dimensionless                     | Dimensionless                     | $E$                | Denotes excess thermodynamic property                |  |   |
| $\bar{H}$          | Molar (or unit-mass) enthalpy  | J/mol [J/kg]                      | Btu/(lb-mol)<br>[Btu/lbm]         | $id$               | Denotes value for an ideal solution                  |  |   |
| $K_i$              | Equilibrium $K$ value, $y_i/x_i$   | Dimensionless                     | Dimensionless                     | $ig$               | Denotes value for an ideal gas                       |  |   |
| $K_j$              | Equilibrium constant for chemical reaction $j$   | Dimensionless                     | Dimensionless                     | $l$                | Denotes liquid phase                                 |  |   |
| $k_1$              | Henry's constant for solute species 1  | kPa                               | psi                               | $lv$               | Denotes phase transition, liquid to vapor            |  |   |
| $M$                | Molar or unit-mass solution property ( $A, G, H, S, U, V$ )  |                                   |                                   | $R$                | Denotes residual thermodynamic property              |  |   |
| $\mathbf{M}$       | Mach number  | Dimensionless                     | Dimensionless                     | $t$                | Denotes total value of property                      |  |   |
| $M_i$              | Molar or unit-mass pure-species property ( $A_i, G_i, H_i, S_i, U_i, V_i$ )  |                                   |                                   | $v$                | Denotes vapor phase                                  |  |   |
| $\bar{M}_i$        | Partial property of species $i$ in solution ( $\bar{A}_i, \bar{G}_i, \bar{H}_i, \bar{S}_i, \bar{U}_i, \bar{V}_i$ ) |                                   |                                   | $\infty$           | Denotes value at infinite dilution                   |  |   |
| $M^R$              | Residual thermodynamic property ( $A^R, C^R, H^R, S^R, \bar{U}^R, V^R$ )   |                                   |                                   | Subscripts         |  |  |   |
| $M^E$              | Excess thermodynamic property ( $A^E, C^E, H^E, S^E, U^E, V^E$ )   |                                   |                                   | $c$                | Denotes value for the critical state                 |  |   |
| $\bar{M}_i^E$      | Partial molar excess thermodynamic property  |                                   |                                   | $cv$               | Denotes the control volume                           |  |   |
| $\Delta M$         | Property change of mixing ( $\Delta A, \Delta G, \Delta H, \Delta S, \Delta U, \Delta V$ )                         |                                   |                                   | $fs$               | Denotes flowing streams                              |  |   |
| $\Delta M_j^\circ$ | Standard property change of reaction $j$ ( $\Delta C_j^\circ, \Delta H_j^\circ, \Delta C_p^\circ$ )                |                                   |                                   | $r$                | Denotes the normal boiling point                     |  |   |
| $m$                | Mass   | kg                                | lbm                               | $rev$              | Denotes a reversible process                         |  |   |
| $\dot{m}$          | Mass flow rate   | kg/s                              | lbm/s                             | Greek Letters      |  |  |   |
| $n$                | Number of moles  |                                   |                                   | $\alpha, \beta$    | As superscripts, identify phases                     |  |   |
| $\dot{n}$          | Molar flow rate  |                                   |                                   | $\beta$            | Volume expansivity                                   | K <sup>-1</sup>                          | °R <sup>-1</sup>                                  |
| $n_i$              | Number of moles of species $i$   |                                   |                                   | $\epsilon_j$       | Reaction coordinate for reaction $j$                 | mol                                      | lb-mol  |
| $P$                | Absolute pressure  | kPa                               | psi                               | $\Gamma_i(T)$      | Defined by Eq. (4-196)                               | J/mol                                    | Btu/(lb-mol)                                      |
|                    |  |                                   |                                   | $\gamma$           | Heat capacity ratio $C_p/C_v$                        | Dimensionless                            | Dimensionless                                     |
|                    |  |                                   |                                   | $\gamma_i$         | Activity coefficient of species $i$ in solution      | Dimensionless                            | Dimensionless                                     |
|                    |  |                                   |                                   | $\kappa$           | Isothermal compressibility                           | kPa <sup>-1</sup>                        | psi <sup>-1</sup>                                 |
|                    |  |                                   |                                   | $\mu_i$            | Chemical potential of species $i$                    | J/mol                                    | Btu/(lb-mol)                                      |
|                    |  |                                   |                                   | $\nu_{ij}$         | Stoichiometric number of species $i$ in reaction $j$ | Dimensionless                            | Dimensionless                                     |
|                    |  |                                   |                                   | $\rho$             | Molar density  | mol/m <sup>3</sup>                       | lb-mol/ft <sup>3</sup>                            |
|                    |  |                                   |                                   | $\sigma$           | As subscript, denotes a heat reservoir               |  |   |
|                    |  |                                   |                                   | $\Phi_i$           | Defined by Eq. (4-304)                               | Dimensionless                            | Dimensionless                                     |
|                    |  |                                   |                                   | $\phi_i$           | Fugacity coefficient of pure species $i$             | Dimensionless                            | Dimensionless                                     |
|                    |  |                                   |                                   | $\hat{\phi}_i$     | Fugacity coefficient of species $i$ in solution      | Dimensionless                            | Dimensionless                                     |
|                    |  |                                   |                                   | $\omega$           | Acentric factor                                      | Dimensionless                            | Dimensionless                                     |

## INTRODUCTION

Thermodynamics is the branch of science that lends substance to the principles of energy transformation in macroscopic systems. The general restrictions shown by experience to apply to all such transformations are known as the laws of thermodynamics. These laws are primitive; they cannot be derived from anything more basic.

The first law of thermodynamics states that energy is conserved, that although it can be altered in form and transferred from one place to another, the total quantity remains constant. Thus the first law of thermodynamics depends on the concept of energy, but conversely energy is an *essential* thermodynamic function because it allows the first law to be formulated. This coupling is characteristic of the primitive concepts of thermodynamics.

The words *system* and *surroundings* are similarly coupled. A system can be an object, a quantity of matter, or a region of space, selected for study and set apart (mentally) from everything else, which is called the surroundings. An envelope, imagined to enclose the system and to separate it from its surroundings, is called the *boundary* of the system.

Attributed to this boundary are special properties which may serve either to *isolate* the system from its surroundings or to provide for *interaction* in specific ways between the system and surroundings. An isolated system exchanges neither matter nor energy with its surroundings. If a system is not isolated, its boundaries may permit exchange of matter or energy or both with its surroundings. If the exchange of matter is allowed, the system is said to be *open*; if only energy and not matter may be exchanged, the system is *closed* (but not isolated), and its mass is constant.

When a system is isolated, it cannot be affected by its surroundings. Nevertheless, changes may occur within the system that are detectable with measuring instruments such as thermometers and pressure gauges. However, such changes cannot continue indefinitely, and the system must eventually reach a final static condition of *internal equilibrium*.

For a closed system which interacts with its surroundings, a final static condition may likewise be reached such that the system is not only internally at equilibrium but also in *external equilibrium* with its surroundings.

The concept of equilibrium is central in thermodynamics, for associated with the condition of internal equilibrium is the concept of *state*. A system has an identifiable, reproducible state when all its *properties*, such as temperature  $T$ , pressure  $P$ , and molar volume  $V$ , are fixed. The concepts of *state* and *property* are again coupled. One can equally well say that the properties of a system are fixed by its state. Although the properties  $T$ ,  $P$ , and  $V$  may be detected with measuring instruments, the existence of the *primitive* thermodynamic properties (see postulates 1 and 3 following) is recognized much more indirectly. The number of properties for which values must be specified in order to fix the state of a system depends on the nature of the system, and is ultimately determined from experience.

When a system is displaced from an equilibrium state, it undergoes a *process*, a change of state, which continues until its properties attain new equilibrium values. During such a process, the system may be caused to interact with its surroundings so as to interchange energy in the forms of heat and work and so to produce in the system changes considered desirable for one reason or another. A process that proceeds so that the system is never displaced more than differentially from an equilibrium state is said to be *reversible*, because such a process can be reversed at any point by an infinitesimal change in external conditions, causing it to retrace the initial path in the opposite direction.

Thermodynamics finds its origin in experience and experiment, from which are formulated a few postulates that form the foundation of the subject. The first two deal with energy.

### POSTULATE 1

*There exists a form of energy, known as **internal energy**, which for systems at internal equilibrium is an intrinsic property of the system, functionally related to the measurable coordinates that characterize the system.*

### POSTULATE 2 (FIRST LAW OF THERMODYNAMICS)

*The **total energy** of any system and its surroundings is conserved.*

Internal energy is quite distinct from such external forms as the kinetic and potential energies of macroscopic bodies. Although it is a macroscopic property, characterized by the macroscopic coordinates  $T$  and  $P$ , internal energy finds its origin in the kinetic and potential energies of molecules and submolecular particles. In applications of the first law of thermodynamics, all forms of energy must be considered, including the internal energy. It is therefore clear that postulate 2 depends on postulate 1. For an isolated system the first law requires that its energy be constant. For a closed (but not isolated) system, the first law requires that energy changes of the system be exactly compensated by energy changes in the surroundings. For such systems energy is exchanged between a system and its surroundings in two forms: heat and work.

*Heat* is energy crossing the system boundary under the influence of a temperature difference or gradient. A quantity of heat  $Q$  represents an amount of energy in transit between a system and its surroundings, and is not a property of the system. The convention with respect to sign makes numerical values of  $Q$  positive when heat is added to the system and negative when heat leaves the system.

*Work* is again energy in transit between a system and its surroundings, but resulting from the displacement of an external force acting on the system. Like heat, a quantity of work  $W$  represents an amount of energy, and is not a property of the system. The sign convention, analogous to that for heat, makes numerical values of  $W$  positive when work is done on the system by the surroundings and negative when work is done on the surroundings by the system.

When applied to closed (constant-mass) systems in which only internal-energy changes occur, the first law of thermodynamics is expressed mathematically as

$$dU^i = dQ + dW \quad (4-1)$$

where  $U^i$  is the total internal energy of the system. Note that  $dQ$  and  $dW$ , differential *quantities* representing energy exchanges between the system and its surroundings, serve to account for the energy change of the surroundings. On the other hand,  $dU^i$  is directly the differential *change* in internal energy of the system. Integration of Eq. (4-1) gives for a finite process

$$\Delta U^i = Q + W \quad (4-2)$$

where  $\Delta U^i$  is the finite change given by the difference between the final and initial values of  $U^i$ . The heat  $Q$  and work  $W$  are finite quantities of heat and work; they are not properties of the system or functions of the thermodynamic coordinates that characterize the system.

**POSTULATE 3**

There exists a property called **entropy**, which for systems at internal equilibrium is an intrinsic property of the system, functionally related to the measurable coordinates that characterize the system. For reversible processes, changes in this property may be calculated by the equation

$$dS' = \frac{dQ_{\text{rev}}}{T} \quad (4-3)$$

where  $S'$  is the total entropy of the system and  $T$  is the absolute temperature of the system.

**POSTULATE 4 (SECOND LAW OF THERMODYNAMICS)**

The entropy change of any system and its surroundings, considered together, resulting from any real process is positive, approaching zero when the process approaches reversibility.

In the same way that the first law of thermodynamics cannot be formulated without the prior recognition of internal energy as a property, so also the second law can have no complete and quantitative expression without a prior assertion of the existence of entropy as a property.

The second law requires that the entropy of an isolated system either increase or, in the limit where the system has reached an equilibrium state, remain constant. For a closed (but not isolated) system it requires that any entropy decrease in either the system or its surroundings be more than compensated by an entropy increase in the other part, or that in the limit where the process is reversible, the total entropy of the system plus its surroundings be constant.

The fundamental thermodynamic properties that arise in connection with the first and second laws of thermodynamics are internal energy and entropy. These properties together with the two laws for which they are essential apply to all types of systems. However, different types of systems are characterized by different sets of measurable coordinates or variables. The type of system most commonly encountered in chemical technology is one for which the primary characteristic variables are temperature  $T$ , pressure  $P$ , molar volume  $V$ , and composition, not all of which are necessarily independent. Such systems are usually made up of fluids (liquid or gas) and are called *PVT* systems.

For closed systems of this kind the work of a reversible process may always be calculated from

$$dW_{\text{rev}} = -PdV^t \quad (4-4)$$

where  $P$  is the absolute pressure and  $V^t$  is the total volume of the system. This equation follows directly from the definition of mechanical work.

**POSTULATE 5**

The macroscopic properties of homogeneous PVT systems at internal equilibrium can be expressed as functions of temperature, pressure, and composition only.

This postulate imposes an idealization, and is the basis for all subsequent property relations for PVT systems. The PVT system serves as a satisfactory model in an enormous number of practical applications. In accepting this model one assumes that the effects of fields (e.g., electric, magnetic, or gravitational) are negligible and that surface and viscous shear effects are unimportant.

Temperature, pressure, and composition are thermodynamic coordinates representing conditions imposed upon or exhibited by the system, and the functional dependence of the thermodynamic properties on these conditions is determined by experiment. This is quite direct for molar or specific volume  $V$ , which can be measured, and leads immediately to the conclusion that there exists an *equation of state* relating molar volume to temperature, pressure, and composition for any particular homogeneous PVT system. The equation of state is a primary tool in applications of thermodynamics.

Postulate 5 affirms that the other molar or specific thermodynamic properties of PVT systems, such as internal energy  $U$  and entropy  $S$ , are also functions of temperature, pressure, and composition. These molar or unit-mass properties, represented by the plain symbols  $V$ ,  $U$ , and  $S$ , are independent of system size and are called *intensive*. Temperature, pressure, and the composition variables, such as mole fraction, are also intensive. Total-system properties ( $V^t$ ,  $U^t$ ,  $S^t$ ) do depend on system size and are *extensive*. For a system containing  $n$  mol of fluid,  $M^t = nM$ , where  $M$  is a molar property.

Applications of the thermodynamic postulates necessarily involve the abstract quantities of internal energy and entropy. The solution of any problem in applied thermodynamics is therefore found through these quantities.

**VARIABLES, DEFINITIONS, AND RELATIONSHIPS**

Consider a single-phase closed system in which there are no chemical reactions. Under these restrictions the composition is fixed. If such a system undergoes a differential, reversible process, then by Eq. (4-1)

$$dU^t = dQ_{\text{rev}} + dW_{\text{rev}}$$

Substitution for  $dQ_{\text{rev}}$  and  $dW_{\text{rev}}$  by Eqs. (4-3) and (4-4) gives

$$dU^t = T dS' - P dV^t$$

Although derived for a reversible process, this equation relates properties only and is valid for any change between equilibrium states in a closed system. It is equally well written as

$$d(nU) = T d(nS) - P d(nV) \quad (4-5)$$

where  $n$  is the number of moles of fluid in the system and is constant for the special case of a closed, nonreacting system. Note that

$$n \equiv n_1 + n_2 + n_3 + \cdots = \sum_i n_i$$

where  $i$  is an index identifying the chemical species present. When  $U$ ,  $S$ , and  $V$  represent *specific* (unit-mass) properties,  $n$  is replaced by  $m$ .

Equation (4-5) shows that for a single-phase, nonreacting, closed system,  $nU = u(nS, nV)$ .

$$\text{Then} \quad d(nU) = \left[ \frac{\partial(nU)}{\partial(nS)} \right]_{nV,n} d(nS) + \left[ \frac{\partial(nU)}{\partial(nV)} \right]_{nS,n} d(nV)$$

where subscript  $n$  indicates that all mole numbers  $n_i$  (and hence  $n$ ) are held constant. Comparison with Eq. (4-5) shows that

$$\left[ \frac{\partial(nU)}{\partial(nS)} \right]_{nV,n} = T \quad \text{and} \quad \left[ \frac{\partial(nU)}{\partial(nV)} \right]_{nS,n} = -P$$

For an **open** single-phase system, we assume that  $nU = \mathcal{U}(nS, nV, n_1, n_2, n_3, \dots)$ . In consequence,

$$d(nU) = \left[ \frac{\partial(nU)}{\partial(nS)} \right]_{nV,n} d(nS) + \left[ \frac{\partial(nU)}{\partial(nV)} \right]_{nS,n} d(nV) + \sum_i \left[ \frac{\partial(nU)}{\partial n_i} \right]_{nS,nV,n_j} dn_i$$

where the summation is over all species present in the system and subscript  $n_j$  indicates that all mole numbers are held constant except the  $i$ th. Define

$$\mu_i \equiv \left[ \frac{\partial(nU)}{\partial n_i} \right]_{nS,nV,n_j}$$

The expressions for  $T$  and  $-P$  of the preceding paragraph and the definition of  $\mu_i$  allow replacement of the partial differential coefficients in the preceding equation by  $T$ ,  $-P$ , and  $\mu_i$ . The result is Eq. (4-6) of Table 4-1, where important equations of this section are collected. Equation (4-6) is the **fundamental property relation** for single-phase PVT systems, from which all other equations connecting properties of

## 4-6 THERMODYNAMICS

**TABLE 4-1 Mathematical Structure of Thermodynamic Property Relations**

| Primary thermodynamic functions   | Fundamental property relations  | For homogeneous systems of constant composition   | Maxwell equations   |
|---|---|---|---|
| $U = TS - PV + \sum_i x_i \mu_i$ (4-7)  | $d(nU) = T d(nS) - P d(nV) + \sum_i \mu_i dn_i$ (4-6)   | $dU = T dS - P dV$ (4-14)   | $\left(\frac{\partial T}{\partial V}\right)_S = -\left(\frac{\partial P}{\partial S}\right)_V$ (4-18) |
| $H \equiv U + PV$ (4-8)   | $d(nH) = T d(nS) + nV dP + \sum_i \mu_i dn_i$ (4-11)  | $dH = T dS + V dP$ (4-15)   | $\left(\frac{\partial T}{\partial P}\right)_S = \left(\frac{\partial V}{\partial S}\right)_P$ (4-19)  |
| $A \equiv U - TS$ (4-9)   | $d(nA) = -nS dT - P d(nV) + \sum_i \mu_i dn_i$ (4-12)   | $dA = -S dT - P dV$ (4-16)  | $\left(\frac{\partial P}{\partial T}\right)_V = \left(\frac{\partial S}{\partial V}\right)_T$ (4-20)  |
| $G \equiv H - TS$ (4-10)  | $d(nG) = -nS dT + nV dP + \sum_i \mu_i dn_i$ (4-13)   | $dG = -S dT + V dP$ (4-17)  | $\left(\frac{\partial V}{\partial T}\right)_P = -\left(\frac{\partial S}{\partial P}\right)_T$ (4-21) |
| $U, H,$ and $S$ as functions of $T$ and $P$ or $T$ and $V$  |   | Partial derivatives   | Total derivatives   |
| $dH = \left(\frac{\partial H}{\partial T}\right)_P dT + \left(\frac{\partial H}{\partial P}\right)_T dP$ (4-22) | $\left(\frac{\partial H}{\partial T}\right)_P = T \left(\frac{\partial S}{\partial T}\right)_P = C_P$ (4-28)  | $dH = C_P dT + \left[V - T \left(\frac{\partial V}{\partial T}\right)_P\right] dP$ (4-32) |   |
| $dS = \left(\frac{\partial S}{\partial T}\right)_P dT + \left(\frac{\partial S}{\partial P}\right)_T dP$ (4-23) | $\left(\frac{\partial H}{\partial P}\right)_T = T \left(\frac{\partial S}{\partial P}\right)_T + V = V - T \left(\frac{\partial V}{\partial T}\right)_P$ (4-29) | $dS = \frac{C_P}{T} dT - \left(\frac{\partial V}{\partial T}\right)_P dP$ (4-33)          |   |
| $dU = \left(\frac{\partial U}{\partial T}\right)_V dT + \left(\frac{\partial U}{\partial V}\right)_T dV$ (4-24) | $\left(\frac{\partial U}{\partial T}\right)_V = T \left(\frac{\partial S}{\partial T}\right)_V = C_V$ (4-30)  | $dU = C_V dT + \left[T \left(\frac{\partial P}{\partial T}\right)_V - P\right] dV$ (4-34) |   |
| $dS = \left(\frac{\partial S}{\partial T}\right)_V dT + \left(\frac{\partial S}{\partial V}\right)_T dV$ (4-25) | $\left(\frac{\partial U}{\partial V}\right)_T = T \left(\frac{\partial S}{\partial V}\right)_T - P = T \left(\frac{\partial P}{\partial T}\right)_V - P$ (4-31) | $dS = \frac{C_V}{T} dT + \left(\frac{\partial P}{\partial T}\right)_V dV$ (4-35)          |   |

$U \equiv$  Internal energy;  $H \equiv$  enthalpy;  $A \equiv$  Helmholtz energy;  $G \equiv$  Gibbs energy.

such systems are derived. The quantity  $\mu_i$  is called the *chemical potential* of species  $i$ , and it plays a vital role in the thermodynamics of phase and chemical equilibria.

Additional property relations follow directly from Eq. (4-6). Because  $n_i = x_i n$ , where  $x_i$  is the mole fraction of species  $i$ , this equation may be rewritten as

$$d(nU) - T d(nS) + P d(nV) - \sum_i \mu_i d(x_i n) = 0$$

Expansion of the differentials and collection of like terms yield

$$\left[ dU - T dS + P dV - \sum_i \mu_i dx_i \right] n + \left[ U - TS + PV - \sum_i x_i \mu_i \right] dn = 0$$

Because  $n$  and  $dn$  are independent and arbitrary, the terms in brackets must separately be zero. This provides two useful equations:

$$dU = T dS - P dV + \sum_i \mu_i dx_i \quad U = TS - PV + \sum_i x_i \mu_i$$

The first is similar to Eq. (4-6). However, Eq. (4-6) applies to a system of  $n$  mol where  $n$  may vary. Here, however,  $n$  is unity and invariant. It is therefore subject to the constraints  $\sum_i x_i = 1$  and  $\sum_i dx_i = 0$ . Mole fractions are not independent of one another, whereas the mole numbers in Eq. (4-6) are.

The second of the preceding equations dictates the possible combinations of terms that may be defined as additional primary functions. Those in common use are shown in Table 4-1 as Eqs. (4-7) through (4-10). Additional thermodynamic properties are related to these and arise by arbitrary definition.

Multiplication of Eq. (4-8) of Table 4-1 by  $n$  and differentiation yield the general expression

$$d(nH) = d(nU) + P d(nV) + nV dP$$

Substitution for  $d(nU)$  by Eq. (4-6) reduces this result to Eq. (4-11). The total differentials of  $nA$  and  $nG$  are obtained similarly and are expressed by Eqs. (4-12) and (4-13). These equations and Eq. (4-6) are equivalent forms of the fundamental property relation, and appear under that heading in Table 4-1. Each expresses a total property— $nU$ ,  $nH$ ,  $nA$ , and  $nG$ —as a function of a particular set of independent

variables, called the *canonical variables* for the property. The choice of which equation to use in a particular application is dictated by convenience. However, the Gibbs energy  $G$  is special, because of its relation to the canonical variables  $T, P$ , and  $\{n_i\}$ , the variables of primary interest in chemical processing. Another set of equations results from the substitutions  $n = 1$  and  $n_i = x_i$ . The resulting equations are of course less general than their parents. Moreover, because the mole fractions are not independent, mathematical operations requiring their independence are invalid.

### CONSTANT-COMPOSITION SYSTEMS

For 1 mol of a homogeneous fluid of constant composition, Eqs. (4-6) and (4-11) through (4-13) simplify to Eqs. (4-14) through (4-17) of Table 4-1. Because these equations are *exact differential expressions*, application of the reciprocity relation for such expressions produces the common Maxwell relations as described in the subsection “Multi-variable Calculus Applied to Thermodynamics” in Sec. 3. These are Eqs. (4-18) through (4-21) of Table 4-1, in which the partial derivatives are taken with composition held constant.

**$U, H,$  and  $S$  as Functions of  $T$  and  $P$  or  $T$  and  $V$**  At constant composition, molar thermodynamic properties can be considered functions of  $T$  and  $P$  (postulate 5). Alternatively, because  $V$  is related to  $T$  and  $P$  through an equation of state,  $V$  can serve rather than  $P$  as the second independent variable. The useful equations for the total differentials of  $U, H,$  and  $S$  that result are given in Table 4-1 by Eqs. (4-22) through (4-25). The obvious next step is substitution for the partial differential coefficients in favor of measurable quantities. This purpose is served by definition of two *heat capacities*, one at constant pressure and the other at constant volume:

$$C_P \equiv \left(\frac{\partial H}{\partial T}\right)_P \quad (4-26)$$

$$C_V \equiv \left(\frac{\partial U}{\partial T}\right)_V \quad (4-27)$$

Both are properties of the material and functions of temperature, pressure, and composition.

Equation (4-15) of Table 4-1 may be divided by  $dT$  and restricted to constant  $P$ , yielding  $(\partial H/\partial T)_P$  as given by the first equality of Eq. (4-28). Division of Eq. (4-15) by  $dP$  and restriction to constant  $T$  yield  $(\partial H/\partial P)_T$  as given by the first equality of Eq. (4-29). Equation (4-28) is completed by Eq. (4-26), and Eq. (4-29) is completed by Eq. (4-21). Similarly, equations for  $(\partial U/\partial T)_V$  and  $(\partial U/\partial V)_T$  derive from Eq. (4-14), and these with Eqs. (4-27) and (4-20) yield Eqs. (4-30) and (4-31) of Table 4-1.

Equations (4-22), (4-26), and (4-29) combine to yield Eq. (4-32); Eqs. (4-23), (4-28), and (4-21) to yield Eq. (4-33); Eqs. (4-24), (4-27), and (4-31) to yield Eq. (4-34); and Eqs. (4-25), (4-30), and (4-20) to yield Eq. (4-35).

Equations (4-32) and (4-33) are general expressions for the enthalpy and entropy of homogeneous fluids at constant composition as functions of  $T$  and  $P$ . Equations (4-34) and (4-35) are general expressions for the internal energy and entropy of homogeneous fluids at constant composition as functions of temperature and molar volume. The coefficients of  $dT$ ,  $dP$ , and  $dV$  are all composed of measurable quantities.

**The Ideal Gas Model** An ideal gas is a model gas comprising imaginary molecules of zero volume that do not interact. Its  $PVT$  behavior is represented by the simplest of equations of state  $PV^{ig} = RT$ , where  $R$  is a universal constant, values of which are given in Table 1-9. The following partial derivatives, all taken at constant composition, are obtained from this equation:

$$\left(\frac{\partial P}{\partial T}\right)_V = \frac{R}{V^{ig}} = \frac{P}{T} \quad \left(\frac{\partial V^{ig}}{\partial T}\right)_P = \frac{R}{P} = \frac{V^{ig}}{T} \quad \left(\frac{\partial P}{\partial V}\right)_T = -\frac{P}{V^{ig}}$$

The first two of these relations when substituted appropriately into Eqs. (4-29) and (4-31) of Table 4-1 lead to very simple expressions for ideal gases:

$$\left(\frac{\partial U^{ig}}{\partial V}\right)_T = \left(\frac{\partial H^{ig}}{\partial P}\right)_T = 0 \quad \left(\frac{\partial S^{ig}}{\partial P}\right)_T = -\frac{R}{P} \quad \left(\frac{\partial S^{ig}}{\partial V}\right)_T = \frac{R}{V^{ig}}$$

Moreover, Eqs. (4-32) through (4-35) become

$$dH^{ig} = C_P^{ig} dT \quad dS^{ig} = \frac{C_P^{ig}}{T} dT - \frac{R}{P} dP$$

$$dU^{ig} = C_V^{ig} dT \quad dS^{ig} = \frac{C_V^{ig}}{T} dT + \frac{R}{V^{ig}} dV$$

In these equations  $V^{ig}$ ,  $U^{ig}$ ,  $C_V^{ig}$ ,  $H^{ig}$ ,  $C_P^{ig}$ , and  $S^{ig}$  are ideal gas state values—the values that a  $PVT$  system would have were the ideal gas equation the true equation of state. They apply equally to pure species and to constant-composition mixtures, and they show that  $U^{ig}$ ,  $C_V^{ig}$ ,  $H^{ig}$ , and  $C_P^{ig}$  are functions of temperature only, independent of  $P$  and  $V$ . The entropy, however, is a function of both  $T$  and  $P$  or of both  $T$  and  $V$ . Regardless of composition, the ideal gas volume is given by  $V^{ig} = RT/P$ , and it provides the basis for comparison with true molar volumes through the *compressibility factor*  $Z$ . By definition,

$$Z \equiv \frac{V}{V^{ig}} = \frac{V}{RT/P} = \frac{PV}{RT} \quad (4-36)$$

The ideal gas state properties of mixtures are directly related to the ideal gas state properties of the constituent pure species. For those properties that are independent of  $P$ — $U^{ig}$ ,  $H^{ig}$ ,  $C_V^{ig}$ , and  $C_P^{ig}$ —the mixture property is the sum of the properties of the pure constituent species, each weighted by its mole fraction:

$$M^{ig} = \sum_i y_i M_i^{ig} \quad (4-37)$$

where  $M^{ig}$  can represent any of the properties listed. For the entropy, which is a function of both  $T$  and  $P$ , an additional term is required to account for the difference in partial pressure of a species between its pure state and its state in a mixture:

$$S^{ig} = \sum_i y_i S_i^{ig} - R \sum_i y_i \ln y_i \quad (4-38)$$

**FIG. 4-1** Region where  $Z$  lies between 0.98 and 1.02, and the ideal-gas equation is a reasonable approximation. [Smith, Van Ness, and Abbott, *Introduction to Chemical Engineering Thermodynamics*, 7th ed., p. 104, McGraw-Hill, New York (2005).]

For the Gibbs energy,  $G^{ig} = H^{ig} - TS^{ig}$ ; whence by Eqs. (4-37) and (4-38):

$$G^{ig} = \sum_i y_i G_i^{ig} + RT \sum_i y_i \ln y_i \quad (4-39)$$

The ideal gas model may serve as a reasonable approximation to reality under conditions indicated by Fig. 4-1.

**Residual Properties** The differences between true and ideal gas state properties are defined as residual properties  $M^R$ :

$$M^R \equiv M - M^{ig} \quad (4-40)$$

where  $M$  is the molar value of an extensive thermodynamic property of a fluid in its actual state and  $M^{ig}$  is its corresponding ideal gas state value at the same  $T$ ,  $P$ , and composition. Residual properties depend on interactions *between* molecules and not on characteristics of individual molecules. Because the ideal gas state presumes the absence of molecular interactions, residual properties reflect deviations from ideality. The most commonly used residual properties are as follows:

$$\begin{aligned} \text{Residual volume } V^R &\equiv V - V^{ig} & \text{Residual enthalpy } H^R &\equiv H - H^{ig} \\ \text{Residual entropy } S^R &\equiv S - S^{ig} & \text{Residual Gibbs energy } G^R &\equiv G - G^{ig} \end{aligned}$$

Useful relations connecting these residual properties derive from Eq. (4-17), an alternative form of which follows from the mathematical identity:

$$d\left(\frac{G}{RT}\right) \equiv \frac{1}{RT} dG - \frac{G}{RT^2} dT$$

## 4-8 THERMODYNAMICS

Substitution for  $dG$  by Eq. (4-17) and for  $G$  by Eq. (4-10) gives, after algebraic reduction,

$$d\left(\frac{G}{RT}\right) = \frac{V}{RT} dP - \frac{H}{RT^2} dT \quad (4-41)$$

This equation may be written for the special case of an ideal gas and subtracted from Eq. (4-41) itself, yielding

$$d\left(\frac{G^R}{RT}\right) = \frac{V^R}{RT} dP - \frac{H^R}{RT^2} dT \quad (4-42)$$

As a consequence, 
$$\frac{V^R}{RT} = \left[ \frac{\partial(G^R/RT)}{\partial P} \right]_T \quad (4-43)$$

and 
$$\frac{H^R}{RT} = -T \left[ \frac{\partial(G^R/RT)}{\partial T} \right]_P \quad (4-44)$$

Equation (4-43) provides a direct link to  $PVT$  correlations through the compressibility factor  $Z$  as given by Eq. (4-36). Thus, with  $V = ZRT/P$ ,

$$V^R \equiv V - V^{ig} = \frac{ZRT}{P} - \frac{RT}{P} = \frac{RT}{P} (Z - 1)$$

This equation in combination with a rearrangement of Eq. (4-43) yields

$$d\left(\frac{G^R}{RT}\right) = \frac{V^R}{RT} dP = (Z - 1) \frac{dP}{P} \quad (\text{constant } T)$$

Integration from  $P = 0$  to arbitrary pressure  $P$  gives

$$\frac{G^R}{RT} = \int_0^P (Z - 1) \frac{dP}{P} \quad (\text{constant } T) \quad (4-45)$$

Smith, Van Ness, and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., pp. 210–211, McGraw-Hill, New York (2005)] show that it is permissible here to set the lower limit of integration  $(G^R/RT)_{P=0}$  equal to zero. Note also that the integrand  $(Z - 1)/P$  remains finite as  $P \rightarrow 0$ . Differentiation of Eq. (4-45) with respect to  $T$  in accord with Eq. (4-44) gives

$$\frac{H^R}{RT} = -T \int_0^P \left( \frac{\partial Z}{\partial T} \right)_P \frac{dP}{P} \quad (\text{constant } T) \quad (4-46)$$

Because  $G = H - TS$  and  $G^{ig} = H^{ig} - TS^{ig}$ , then by difference,  $G^R = H^R - TS^R$ , and

$$\frac{S^R}{R} = \frac{H^R}{RT} - \frac{G^R}{RT} \quad (4-47)$$

Equations (4-45) through (4-47) provide the basis for calculation of residual properties from  $PVT$  correlations. They may be put into *generalized* form by substitution of the relationships

$$P = P_c P_r \quad T = T_c T_r \\ dP = P_c dP_r \quad dT = T_c dT_r$$

The resulting equations are

$$\frac{G^R}{RT} = \int_0^{P_r} (Z - 1) \frac{dP_r}{P_r} \quad (4-48)$$

$$\frac{H^R}{RT_c} = -T_c^2 \int_0^{P_r} \left( \frac{\partial Z}{\partial T_r} \right) \frac{dP_r}{P_r} \quad (4-49)$$

The terms on the right sides of these equations depend only on the upper limit  $P_r$  of the integrals and on the reduced temperature at which they are evaluated. Thus, values of  $G^R/RT$  and  $H^R/RT_c$  may be determined once and for all at any reduced temperature and pressure from generalized compressibility factor data.

## PROPERTY CALCULATIONS FOR GASES AND VAPORS

The most satisfactory calculation procedure for the thermodynamic properties of gases and vapors is based on ideal gas state heat capacities and residual properties. Of primary interest are the enthalpy and entropy; these are given by rearrangement of the residual property definitions:

$$H = H^{ig} + H^R \quad \text{and} \quad S = S^{ig} + S^R$$

These are simple sums of the ideal gas and residual properties, evaluated separately.

### EVALUATION OF ENTHALPY AND ENTROPY IN THE IDEAL GAS STATE

For the ideal gas state at constant composition:

$$dH^{ig} = C_P^{ig} dT \quad \text{and} \quad dS^{ig} = C_P^{ig} \frac{dT}{T} - R \frac{dP}{P}$$

Integration from an initial ideal gas *reference state* at conditions  $T_0$  and  $P_0$  to the ideal gas state at  $T$  and  $P$  gives

$$H^{ig} = H_0^{ig} + \int_{T_0}^T C_P^{ig} dT \\ S^{ig} = S_0^{ig} + \int_{T_0}^T C_P^{ig} \frac{dT}{T} - R \ln \frac{P}{P_0}$$

Substitution into the equations for  $H$  and  $S$  yields

$$H = H_0^{ig} + \int_{T_0}^T C_P^{ig} dT + H^R \quad (4-50)$$

$$S = S_0^{ig} + \int_{T_0}^T C_P^{ig} \frac{dT}{T} - R \ln \frac{P}{P_0} + S^R \quad (4-51)$$

The reference state at  $T_0$  and  $P_0$  is arbitrarily selected, and the values assigned to  $H_0^{ig}$  and  $S_0^{ig}$  are also arbitrary. In practice, only *changes* in  $H$  and  $S$  are of interest, and fixed reference state values ultimately cancel in their calculation.

The ideal gas state heat capacity  $C_P^{ig}$  is a function of  $T$  but not of  $P$ . For a mixture the heat capacity is simply the molar average  $\sum_i y_i C_{P,i}^{ig}$ . Empirical equations relating  $C_P^{ig}$  to  $T$  are available for many pure gases; a common form is

$$\frac{C_P^{ig}}{R} = A + BT + CT^2 + DT^{-2} \quad (4-52)$$

where  $A$ ,  $B$ ,  $C$ , and  $D$  are constants characteristic of the particular gas, and either  $C$  or  $D$  is zero. The ratio  $C_P^{ig}/R$  is dimensionless; thus the units of  $C_P^{ig}$  are those of  $R$ . Data for ideal gas state heat capacities are given for many substances in Table 2-155.

Evaluation of the integrals  $\int C_P^{ig} dT$  and  $\int (C_P^{ig}/T) dT$  is accomplished by substitution for  $C_P^{ig}$ , followed by integration. For temperature limits of  $T_0$  and  $T$  and with  $\tau \equiv T/T_0$ , the equations that follow from Eq. (4-52) are

$$\int_{T_0}^T \frac{C_P^{ig}}{R} dT = AT_0(\tau - 1) + \frac{B}{2} T_0^2(\tau^2 - 1) + \frac{C}{3} T_0^3(\tau^3 - 1) + \frac{D}{T_0} \left( \frac{\tau - 1}{\tau} \right) \quad (4-53)$$

$$\int_{T_0}^T \frac{C_P^{ig}}{RT} dT = A \ln \tau + \left[ BT_0 + \left( CT_0^2 + \frac{D}{\tau^2 T_0^2} \right) \left( \frac{\tau + 1}{2} \right) \right] (\tau - 1) \quad (4-54)$$

Equations (4-50) and (4-51) may sometimes be advantageously expressed in alternative form through use of mean heat capacities:

$$H = H_0^{ig} + \langle C_P^{ig} \rangle_H (T - T_0) + H^R \quad (4-55)$$

$$S = S_0^{ig} + \langle C_P^{ig} \rangle_S \ln \frac{T}{T_0} - R \ln \frac{P}{P_0} + S^R \quad (4-56)$$

where  $\langle C_P^{ig} \rangle_H$  and  $\langle C_P^{ig} \rangle_S$  are mean heat capacities specific, respectively, for enthalpy and entropy calculations. They are given by the following equations:

$$\frac{\langle C_P^{ig} \rangle_H}{R} = A + \frac{B}{2} T_0 (\tau + 1) + \frac{C}{3} T_0^2 (\tau^2 + \tau + 1) + \frac{D}{\tau T_0^2} \quad (4-57)$$

$$\frac{\langle C_P^{ig} \rangle_S}{R} = A + \left[ B T_0 + \left( C T_0^2 + \frac{D}{\tau^2 T_0^2} \right) \left( \frac{\tau + 1}{2} \right) \right] \frac{\tau - 1}{\ln \tau} \quad (4-58)$$

## RESIDUAL ENTHALPY AND ENTROPY FROM PVT CORRELATIONS

The residual properties of gases and vapors depend on their PVT behavior. This is often expressed through correlations for the compressibility factor  $Z$ , defined by Eq. (4-36). Analytical expressions for  $Z$  as functions of  $T$  and  $P$  or  $T$  and  $V$  are known as *equations of state*. They may also be reformulated to give  $P$  as a function of  $T$  and  $V$  or  $V$  as a function of  $T$  and  $P$ .

**Virial Equations of State** The virial equation in *density* is an infinite series expansion of the compressibility factor  $Z$  in powers of molar density  $\rho$  (or reciprocal molar volume  $V^{-1}$ ) about the real gas state at zero density (zero pressure):

$$Z = 1 + B\rho + C\rho^2 + D\rho^3 + \dots \quad (4-59)$$

The density series virial coefficients  $B$ ,  $C$ ,  $D$ ,  $\dots$  depend on temperature and composition only. In practice, truncation is to two or three terms. The composition dependencies of  $B$  and  $C$  are given by the exact *mixing rules*

$$B = \sum_i \sum_j y_i y_j B_{ij} \quad (4-60)$$

$$C = \sum_i \sum_j \sum_k y_i y_j y_k C_{ijk} \quad (4-61)$$

where  $y_i$ ,  $y_j$ , and  $y_k$  are mole fractions for a gas mixture and  $i$ ,  $j$ , and  $k$  identify species.

The coefficient  $B_{ij}$  characterizes a bimolecular interaction between molecules  $i$  and  $j$ , and therefore  $B_{ij} = B_{ji}$ . Two kinds of second virial coefficient arise:  $B_{ii}$  and  $B_{jj}$ , wherein the subscripts are the same ( $i=j$ ), and  $B_{ij}$ , wherein they are different ( $i \neq j$ ). The first is a virial coefficient for a pure species; the second is a mixture property, called a *cross coefficient*. Similarly for the third virial coefficients:  $C_{iii}$ ,  $C_{jjj}$ , and  $C_{kkk}$  are for the pure species, and  $C_{ijj} = C_{jii} = C_{jij} = \dots$  are cross coefficients.

Although the virial equation itself is easily rationalized on empirical grounds, the mixing rules of Eqs. (4-60) and (4-61) follow rigorously from the methods of statistical mechanics. The temperature derivatives of  $B$  and  $C$  are given exactly by

$$\frac{dB}{dT} = \sum_i \sum_j y_i y_j \frac{dB_{ij}}{dT} \quad (4-62)$$

$$\frac{dC}{dT} = \sum_i \sum_j \sum_k y_i y_j y_k \frac{dC_{ijk}}{dT} \quad (4-63)$$

An alternative form of the virial equation expresses  $Z$  as an expansion in powers of pressure about the real gas state at zero pressure (zero density):

$$Z = 1 + B'P + C'P^2 + D'P^3 + \dots \quad (4-64)$$

Equation (4-64) is the virial equation in *pressure*, and  $B'$ ,  $C'$ ,  $D'$ ,  $\dots$  are the pressure series virial coefficients. Again, truncation is to two

or three terms, with  $B'$  and  $C'$  depending on temperature and composition only. Moreover, the two sets of coefficients are related:

$$B' = B/RT \quad (4-65)$$

$$C' = (C - B^2)/(RT)^2 \quad (4-66)$$

Values can often be found for  $B$ , but not so often for  $C$ . Generalized correlations for both  $B$  and  $C$  are given by Meng, Duan, and Li [*Fluid Phase Equilibria* **226**: 109–120 (2004)].

For pressures up to several bars, the two-term expansion in pressure, with  $B'$  given by Eq. (4-65), is usually preferred:

$$Z = 1 + B'P = 1 + BP/RT \quad (4-67)$$

For supercritical temperatures, it is satisfactory to ever higher pressures as the temperature increases. For pressures above the range where Eq. (4-67) is useful, but below the critical pressure, the virial expansion in density truncated to three terms is usually suitable:

$$Z = 1 + B\rho + C\rho^2 \quad (4-68)$$

Equations for residual enthalpy and entropy may be developed from each of these expressions. Consider first Eq. (4-67), which is explicit in volume. Equations (4-45) and (4-46) are therefore applicable. Direct substitution for  $Z$  in Eq. (4-45) gives

$$\frac{G^R}{RT} = \frac{BP}{RT} \quad (4-69)$$

Differentiation of Eq. (4-67) yields

$$\left( \frac{\partial Z}{\partial T} \right)_P = \left( \frac{dB}{dT} - \frac{B}{T} \right) \frac{P}{RT}$$

By Eq. (4-46),

$$\frac{H^R}{RT} = \frac{P}{R} \left( \frac{B}{T} - \frac{dB}{dT} \right) \quad (4-70)$$

and by Eq. (4-47),

$$\frac{S^R}{R} = - \frac{P}{R} \frac{dB}{dT} \quad (4-71)$$

An extensive set of three-parameter corresponding-states correlations has been developed by Pitzer and coworkers [Pitzer, *Thermodynamics*, 3d ed., App. 3, McGraw-Hill, New York (1995)]. Particularly useful is the one for the second virial coefficient. The basic equation is

$$\frac{BP_c}{RT_c} = B^0 + \omega B^1 \quad (4-72)$$

with the *acentric factor* defined by Eq. (2-17). For pure chemical species  $B^0$  and  $B^1$  are functions of reduced temperature only. Substitution for  $B$  in Eq. (4-67) by this expression gives

$$Z = 1 + (B^0 + \omega B^1) \frac{P_r}{T_r} \quad (4-73)$$

By differentiation,

$$\left( \frac{\partial Z}{\partial T_r} \right)_{P_r} = P_r \left( \frac{dB^0/dT_r}{T_r} - \frac{B^0}{T_r^2} \right) + \omega P_r \left( \frac{dB^1/dT_r}{T_r} - \frac{B^1}{T_r^2} \right)$$

Upon substitution of these equations into Eqs. (4-48) and (4-49), integration yields

$$\frac{G^R}{RT} = (B^0 + \omega B^1) \frac{P_r}{T_r} \quad (4-74)$$

$$\frac{H^R}{RT_c} = P_r \left[ B^0 - T_r \frac{dB^0}{dT_r} + \omega \left( B^1 - T_r \frac{dB^1}{dT_r} \right) \right] \quad (4-75)$$

The residual entropy follows from Eq. (4-47):

$$\frac{S^R}{R} = - P_r \left( \frac{dB^0}{dT_r} + \omega \frac{dB^1}{dT_r} \right) \quad (4-76)$$

## 4-10 THERMODYNAMICS

In these equations,  $B^0$  and  $B^1$  and their derivatives are well represented by Abbott's correlations [Smith and Van Ness, *Introduction to Chemical Engineering Thermodynamics*, 3d ed., p. 87, McGraw-Hill, New York (1975)]:

$$B^0 = 0.083 - \frac{0.422}{T_r^{1.6}} \quad (4-77)$$

$$B^1 = 0.139 - \frac{0.172}{T_r^{4.2}} \quad (4-78)$$

$$\frac{dB^0}{dT_r} = \frac{0.675}{T_r^{2.6}} \quad (4-79)$$

$$\frac{dB^1}{dT_r} = \frac{0.722}{T_r^{5.2}} \quad (4-80)$$

Although limited to pressures where the two-term virial equation in pressure has approximate validity, these correlations are applicable for most chemical processing conditions. As with all generalized correlations, they are least accurate for polar and associating molecules.

Although developed for pure materials, these correlations can be extended to gas or vapor mixtures. Basic to this extension are the mixing rules for the second virial coefficient and its temperature derivative as given by Eqs. (4-60) and (4-62). Values for the cross coefficients  $B_{ij}$ , with  $i \neq j$ , and their derivatives are provided by Eq. (4-72) written in extended form:

$$B_{ij} = \frac{RT_{cij}}{P_{cij}} (B^0 + \omega_{ij} B^1) \quad (4-81)$$

where  $B^0$ ,  $B^1$ ,  $dB^0/dT_r$ , and  $dB^1/dT_r$  are the same functions of  $T_r$  as given by Eqs. (4-77) through (4-80). Differentiation produces

$$\begin{aligned} \frac{dB_{ij}}{dT} &= \frac{RT_{cij}}{P_{cij}} \left( \frac{dB^0}{dT} + \omega_{ij} \frac{dB^1}{dT} \right) \\ \frac{dB_{ij}}{dT} &= \frac{R}{P_{cij}} \left( \frac{dB^0}{dT_{rij}} + \omega_{ij} \frac{dB^1}{dT_{rij}} \right) \end{aligned} \quad (4-82)$$

where  $T_{rij} = T/T_{cij}$ . The following combining rules for  $\omega_{ij}$ ,  $T_{cij}$ , and  $P_{cij}$  are given by Prausnitz, Lichtenthaler, and de Azevedo [*Molecular Thermodynamics of Fluid-Phase Equilibria*, 2d ed., pp. 132 and 162, Prentice-Hall, Englewood Cliffs, N.J. (1986)]:

$$\omega_{ij} = \frac{\omega_i + \omega_j}{2} \quad (4-83)$$

$$T_{cij} = (T_{ci} T_{cj})^{1/2} (1 - k_{ij}) \quad (4-84)$$

$$P_{cij} = \frac{Z_{cij} RT_{cij}}{V_{cij}} \quad (4-85)$$

with 
$$Z_{cij} = \frac{Z_{ci} + Z_{cj}}{2} \quad (4-86)$$

and 
$$V_{cij} = \left( \frac{V_{ci}^{1/3} + V_{cj}^{1/3}}{2} \right)^3 \quad (4-87)$$

In Eq. (4-84),  $k_{ij}$  is an empirical interaction parameter specific to an  $i-j$  molecular pair. When  $i=j$  and for chemically similar species,  $k_{ij}=0$ . Otherwise, it is a small (usually) positive number evaluated from minimal PVT data or, absence data, set equal to zero.

When  $i=j$ , all equations reduce to the appropriate values for a pure species. When  $i \neq j$ , these equations define a set of interaction parameters without physical significance. For a mixture, values of  $B_{ij}$  and  $dB_{ij}/dT$  from Eqs. (4-81) and (4-82) are substituted into Eqs. (4-60) and (4-62) to provide values of the mixture second virial coefficient

$B$  and its temperature derivative. Values of  $H^R$  and  $S^R$  are then given by Eqs. (4-70) and (4-71).

A primary virtue of Abbott's correlations for second virial coefficients is simplicity. More complex correlations of somewhat wider applicability include those by Tsionopoulos [*AIChE J.* **20**: 263–272 (1974); *ibid.*, **21**: 827–829 (1975); *ibid.*, **24**: 1112–1115 (1978); *Adv. in Chemistry Series 182*, pp. 143–162 (1979)] and Hayden and O'Connell [*Ind. Eng. Chem. Proc. Des. Dev.* **14**: 209–216 (1975)]. For aqueous systems see Bishop and O'Connell [*Ind. Eng. Chem. Res.*, **44**: 630–633 (2005)].

Because Eq. (4-68) is explicit in  $P$ , it is incompatible with Eqs. (4-45) and (4-46), and they must be transformed to make  $V$  (or molar density  $\rho$ ) the variable of integration. The resulting equations are given by Smith, Van Ness, and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., pp. 216–217, McGraw-Hill, New York (2005)]:

$$\frac{G^R}{RT} = Z - 1 - \ln Z + \int_0^{\rho} (Z - 1) \frac{d\rho}{\rho} \quad (4-88)$$

$$\frac{H^R}{RT} = Z - 1 - T \int_0^{\rho} \left( \frac{\partial Z}{\partial T} \right)_{\rho} \frac{d\rho}{\rho} \quad (4-89)$$

By differentiation of Eq. (4-68),

$$\left( \frac{\partial Z}{\partial T} \right)_{\rho} = \frac{dB}{dT} \rho + \frac{dC}{dT} \rho^2$$

Substituting in Eqs. (4-88) and (4-89) for  $Z$  by Eq. (4-68) and in Eq. (4-89) for the derivative yields, upon integration and reduction,

$$\frac{G^R}{RT} = 2B\rho + \frac{3}{2}C\rho^2 - \ln Z \quad (4-90)$$

$$\frac{H^R}{RT} = \left( B - T \frac{dB}{dT} \right) \rho + \left( C - \frac{T}{2} \frac{dC}{dT} \right) \rho^2 \quad (4-91)$$

The residual entropy is given by Eq. (4-47).

In a process calculation,  $T$  and  $P$ , rather than  $T$  and  $\rho$  (or  $T$  and  $V$ ), are usually the favored independent variables. Applications of Eqs. (4-90) and (4-91) therefore require prior solution of Eq. (4-68) for  $Z$  or  $\rho$ . With  $Z = P/\rho RT$ , Eq. (4-68) may be written in two equivalent forms:

$$Z^3 - Z^2 - \left( \frac{BP}{RT} \right) Z - \frac{CP^2}{(RT)^2} = 0 \quad (4-92)$$

$$\rho^3 + \left( \frac{B}{C} \right) \rho^2 + \left( \frac{1}{C} \right) \rho - \frac{P}{CRT} = 0 \quad (4-93)$$

In the event that three real roots obtain for these equations, only the largest  $Z$  (smallest  $\rho$ ), appropriate for the vapor phase, has physical significance, because the virial equations are suitable only for vapors and gases.

Data for third virial coefficients are often lacking, but generalized correlations are available. Equation (4-68) may be rewritten in reduced form as

$$Z = 1 + \hat{B} \frac{P_r}{T_r Z} + \hat{C} \left( \frac{P_r}{T_r Z} \right)^2 \quad (4-94)$$

where  $\hat{B}$  is the reduced second virial coefficient given by Eq. (4-72). Thus by definition,

$$\hat{B} \equiv \frac{BP_c}{RT_c} = B^0 + \omega B^1 \quad (4-95)$$

The reduced third virial coefficient  $\hat{C}$  is defined as

$$\hat{C} \equiv \frac{CP_c^2}{R^2 T_c^2} \quad (4-96)$$

A Pitzer-type correlation for  $\hat{C}$  is then written as

$$\hat{C} = C^0 + \omega C^1 \quad (4-97)$$

Correlations for  $C^0$  and  $C^1$  with reduced temperature are

$$C^0 = 0.01407 + \frac{0.02432}{T_r} - \frac{0.00313}{T_r^{10.5}} \quad (4-98)$$

$$C^1 = -0.02676 + \frac{0.05539}{T_r^{2.7}} - \frac{0.00242}{T_r^{10.5}} \quad (4-99)$$

The first is given by, and the second is inspired by, Orbey and Vera [AIChE J. **29**: 107–113 (1983)].

Equation (4-94) is cubic in  $Z$ , with  $T_r$  and  $P_r$  specified, solution for  $Z$  is by iteration. An initial guess of  $Z = 1$  on the right side usually leads to rapid convergence.

Another class of equations, known as *extended virial equations*, was introduced by Benedict, Webb, and Rubin [J. Chem. Phys. **8**: 334–345 (1940); **10**: 747–758 (1942)]. This equation contains eight parameters, all functions of composition. It and its modifications, despite their complexity, find application in the petroleum and natural gas industries for light hydrocarbons and a few other commonly encountered gases [see Lee and Kesler, AIChE J., **21**: 510–527 (1975)].

**Cubic Equations of State** The modern development of cubic equations of state started in 1949 with publication of the Redlich-Kwong (RK) equation [Chem. Rev., **44**: 233–244 (1949)], and many others have since been proposed. An extensive review is given by Valderrama [Ind. Eng. Chem. Res. **42**: 1603–1618 (2003)]. Of the equations published more recently, the two most popular are the Soave-Redlich-Kwong (SRK) equation, a modification of the RK equation [Chem. Eng. Sci. **27**: 1197–1203 (1972)] and the Peng-Robinson (PR) equation [Ind. Eng. Chem. Fundam. **15**: 59–64 (1976)]. All are encompassed by a *generic* cubic equation of state, written as

$$P = \frac{RT}{V-b} - \frac{a(T)}{(V+\epsilon b)(V+\sigma b)} \quad (4-100)$$

For a specific form of this equation,  $\epsilon$  and  $\sigma$  are pure numbers, the same for all substances, whereas parameters  $a(T)$  and  $b$  are substance-dependent. Suitable estimates of the parameters in cubic equations of state are usually found from values for the critical constants  $T_c$  and  $P_c$ . The procedure is discussed by Smith, Van Ness, and Abbott [Introduction to Chemical Engineering Thermodynamics, 7th ed., pp. 93–94, McGraw-Hill, New York (2005)], and for Eq. (4-100) the appropriate equations are given as

$$a(T) = \psi \frac{\alpha(T_r) R^2 T_c^2}{P_c} \quad (4-101)$$

$$b = \Omega \frac{RT_c}{P_c} \quad (4-102)$$

Function  $\alpha(T_r)$  is an empirical expression, specific to a particular form of the equation of state. In these equations  $\psi$  and  $\Omega$  are pure numbers, independent of substance and determined for a particular equation of state from the values assigned to  $\epsilon$  and  $\sigma$ .

As an equation cubic in  $V$ , Eq. (4-100) has three volume roots, of which two may be complex. Physically meaningful values of  $V$  are always real, positive, and greater than parameter  $b$ . When  $T > T_c$ , solution for  $V$  at any positive value of  $P$  yields only one real positive root. When  $T = T_c$ , this is also true, except at the critical pressure, where three roots exist, all equal to  $V_c$ . For  $T < T_c$ , only one real positive (liquidlike) root exists at high pressures, but for a range of lower pressures there are three. Here, the middle root is of no significance; the smallest root is a liquid or liquidlike volume, and the largest root is a vapor or vaporlike volume.

Equation (4-100) may be rearranged to facilitate its solution either for a vapor or vaporlike volume or for a liquid or liquidlike volume.

$$\text{Vapor:} \quad V = \frac{RT}{P} + b - \frac{a(T)}{P} \frac{V-b}{(V+\epsilon b)(V+\sigma b)} \quad (4-103a)$$

$$\text{Liquid:} \quad V = b + (V+\epsilon b)(V+\sigma b) \left[ \frac{RT - bP - VP}{a(T)} \right] \quad (4-103b)$$

Solution for  $V$  is most convenient with the solve routine of a software package. An initial estimate for  $V$  in Eq. (4-103a) is the ideal gas value  $RT/P$ ; for Eq. (4-103b) it is  $V = b$ . In either case, iteration is initiated by substituting the estimate on the right side. The resulting value of  $V$  on the left is returned to the right side, and the process continues until the change in  $V$  is suitably small.

Equations for  $Z$  equivalent to Eqs. (4-103) are obtained by substituting  $V = ZRT/P$ .

$$\text{Vapor:} \quad Z = 1 + \beta - q\beta \frac{Z - \beta}{(Z + \epsilon\beta)(Z + \sigma\beta)} \quad (4-104a)$$

$$\text{Liquid:} \quad Z = \beta + (Z + \epsilon b)(Z + \sigma b) \left( \frac{1 + \beta - Z}{q\beta} \right) \quad (4-104b)$$

$$\text{where by definition} \quad \beta \equiv \frac{bP}{RT} \quad (4-105)$$

$$\text{and} \quad q \equiv \frac{a(T)}{bRT} \quad (4-106)$$

These dimensionless quantities provide simplification, and when combined with Eqs. (4-101) and (4-102), they yield

$$\beta = \Omega \frac{P_r}{T_r} \quad (4-107)$$

$$q = \frac{\Psi\alpha(T_r)}{\Omega T_r} \quad (4-108)$$

In Eq. (4-104a) the initial estimate is  $Z = 1$ ; in Eq. (4-104b) it is  $Z = \beta$ . Iteration follows the same pattern as for Eqs. (4-103). The final value of  $Z$  yields the volume root through  $V = ZRT/P$ .

Equations of state, such as the Redlich-Kwong (RK) equation, which expresses  $Z$  as a function of  $T_r$  and  $P_r$  only, yield two-parameter corresponding-states correlations. The SRK equation and the PR equation, in which the acentric factor  $\omega$  enters through function  $\alpha(T_r; \omega)$  as an additional parameter, yield three-parameter corresponding-states correlations. The numerical assignments for parameters  $\epsilon$ ,  $\sigma$ ,  $\Omega$ , and  $\Psi$  are given in Table 4-2. Expressions are also given for  $\alpha(T_r; \omega)$  for the SRK and PR equations.

As shown by Smith, Van Ness, and Abbott [Introduction to Chemical Engineering Thermodynamics, 7th ed., pp. 218–219, McGraw-Hill, New York (2005)], Eqs. (4-104) in conjunction with Eqs. (4-88), (4-89), and (4-47) lead to

$$\frac{G^R}{RT} = Z - 1 - \ln(Z - \beta) - qI \quad (4-109)$$

$$\frac{H^R}{RT} = Z - 1 + \left[ \frac{d \ln \alpha(T_r)}{d \ln T_r} - 1 \right] qI \quad (4-110)$$

**TABLE 4-2 Parameter Assignments for Cubic Equations of State\***

For use with Eqs. (4-104) through (4-106)

| Eq. of state | $\alpha(T_r)$                                | $\sigma$       | $\epsilon$     | $\Omega$ | $\Psi$  |

$\dagger \alpha_{\text{SRK}}(T_r; \omega) = [1 + (0.480 + 1.574\omega - 0.176\omega^2)(1 - T_r^{1/2})]^2$

$\ddagger \alpha_{\text{PR}}(T_r; \omega) = [1 + (0.37464 + 1.54226\omega - 0.26992\omega^2)(1 - T_r^{1/2})]^2$

## 4-12 THERMODYNAMICS

$$\frac{S^R}{R} = \ln(Z - \beta) + \frac{d \ln \alpha(T_r)}{d \ln T_r} qI \quad (4-111)$$

$$\text{where } I = \frac{1}{\sigma - \epsilon} \ln \left( \frac{Z + \sigma\beta}{Z + \epsilon\beta} \right) \quad (4-112)$$

Preliminary to application of these equations  $Z$  is found by solution of either Eq. (4-104a) or (4-104b).

Cubic equations of state may be applied to mixtures through expressions that give the parameters as functions of composition. No established theory prescribes the form of this dependence, and empirical *mixing rules* are often used to relate mixture parameters to pure-species parameters. The simplest realistic expressions are a linear mixing rule for parameter  $b$  and a quadratic mixing rule for parameter  $a$

$$b = \sum_i x_i b_i \quad (4-113)$$

$$a = \sum_i \sum_j x_i x_j a_{ij} \quad (4-114)$$

with  $a_{ij} = a_{ji}$ . The  $a_{ij}$  are of two types: pure-species parameters (like subscripts) and interaction parameters (unlike subscripts). Parameter  $b_i$  is for pure species  $i$ . The interaction parameter  $a_{ij}$  is often evaluated from pure-species parameters by a geometric mean *combining rule*

$$a_{ij} = (a_i a_j)^{1/2} \quad (4-115)$$

These traditional equations yield mixture parameters solely from parameters for the pure constituent species. They are most likely to be satisfactory for mixtures comprised of simple and chemically similar molecules.

**Pitzer's Generalized Correlations** In addition to the corresponding-states correlation for the second virial coefficient, Pitzer and coworkers [*Thermodynamics*, 3d ed., App. 3, McGraw-Hill, New York (1995)] developed a full set of generalized correlations. They have as their basis an equation for the compressibility factor, as given by Eq. (2-63):

$$Z = Z^0 + \omega Z^1 \quad (2-63)$$

where  $Z^0$  and  $Z^1$  are each functions of reduced temperature  $T_r$  and reduced pressure  $P_r$ . Acentric factor  $\omega$  is defined by Eq. (2-17). Correlations for  $Z$  appear in Sec. 2.

Generalized correlations are developed here for the residual enthalpy and residual entropy from Eqs. (4-48) and (4-49). Substitution for  $Z$  by Eq. (2-63) puts Eq. (4-48) into generalized form:

$$\frac{G^R}{RT} = \int_0^{P_r} (Z^0 - 1) \frac{dP_r}{P_r} + \omega \int_0^{P_r} Z^1 \frac{dP_r}{P_r} \quad (4-116)$$

Differentiation of Eq. (2-63) yields

$$\left( \frac{\partial Z}{\partial T_r} \right)_{P_r} = \left( \frac{\partial Z^0}{\partial T_r} \right)_{P_r} + \omega \left( \frac{\partial Z^1}{\partial T_r} \right)_{P_r}$$

Substitution for  $(\partial Z / \partial T_r)_{P_r}$  in Eq. (4-49) gives

$$\frac{H^R}{RT_c} = -T_r^2 \int_0^{P_r} \left( \frac{\partial Z^0}{\partial T_r} \right)_{P_r} \frac{dP_r}{P_r} - \omega T_r^2 \int_0^{P_r} \left( \frac{\partial Z^1}{\partial T_r} \right)_{P_r} \frac{dP_r}{P_r} \quad (4-117)$$

$$\text{By Eq. (4-47), } \frac{S^R}{R} = \frac{1}{T_r} \left( \frac{H^R}{RT_c} \right) - \frac{G^R}{RT}$$

Combination of Eqs. (4-116) and (4-117) leads to

$$\frac{S^R}{R} = - \int_0^{P_r} \left[ T_r \left( \frac{\partial Z^0}{\partial T_r} \right)_{P_r} + Z^0 - 1 \right] \frac{dP_r}{P_r} - \omega \int_0^{P_r} \left[ T_r \left( \frac{\partial Z^1}{\partial T_r} \right)_{P_r} + Z^1 \right] \frac{dP_r}{P_r}$$

If the first terms on the right sides of Eq. (4-117) and of this equation (including the minus signs) are represented by  $(H^R)^0/RT_c$  and  $(S^R)^0/R$  and if the second terms, excluding  $\omega$  but including the minus signs, are represented by  $(H^R)^1/RT_c$  and  $(S^R)^1/R$ , then

$$\frac{H^R}{RT_c} = \frac{(H^R)^0}{RT_c} + \omega \frac{(H^R)^1}{RT_c} \quad (4-118)$$

$$\frac{S^R}{R} = \frac{(S^R)^0}{R} + \omega \frac{(S^R)^1}{R} \quad (4-119)$$

Pitzer's original correlations for  $Z$  and the derived quantities were determined graphically and presented in tabular form. Since then, analytical refinements to the tables have been developed, with extended range and accuracy. The most popular Pitzer-type correlation is that of Lee and Kesler [*AIChE J.* **21**: 510–527 (1975); see also Smith, Van Ness, and Abbott, *Introduction to Chemical Engineering Thermodynamics*, 5th, 6th, and 7th eds., App. E, McGraw-Hill, New York (1996, 2001, 2005)]. These tables cover both the liquid and gas phases and span the ranges  $0.3 \leq T_r \leq 4.0$  and  $0.01 \leq P_r \leq 10.0$ . They list values of  $Z^0$ ,  $Z^1$ ,  $(H^R)^0/RT_c$ ,  $(H^R)^1/RT_c$ ,  $(S^R)^0/R$ , and  $(S^R)^1/R$ .

Lee and Kesler also included a Pitzer-type correlation for vapor pressures:

$$\ln P_r^{\text{sat}}(T_r) = \ln P_r^0(T_r) + \omega \ln P_r^1(T_r) \quad (4-120)$$

$$\text{where } \ln P_r^0(T_r) = 5.92714 - \frac{6.09648}{T_r} - 1.28862 \ln T_r + 0.1693477 T_r^6 \quad (4-121)$$

$$\text{and } \ln P_r^1(T_r) = 15.2518 - \frac{15.6875}{T_r} - 13.4721 \ln T_r + 0.435777 T_r^6 \quad (4-122)$$

The value of  $\omega$  to be used with Eq. (4-120) is found from the correlation by requiring that it reproduce the normal boiling point; that is,  $\omega$  for a particular substance is determined from

$$\omega = \frac{\ln P_{r_s}^{\text{sat}} - \ln P_r^0(T_{r_s})}{\ln P_r^1(T_{r_s})} \quad (4-123)$$

where  $T_{r_s}$  is the reduced normal boiling point and  $P_{r_s}^{\text{sat}}$  is the reduced vapor pressure corresponding to 1 standard atmosphere (1.01325 bar).

Although the tables representing the Pitzer correlations are based on data for pure materials, they may also be used for the calculation of mixture properties. A set of recipes is required relating the parameters  $T_c$ ,  $P_c$ , and  $\omega$  for a mixture to the pure-species values and to composition. One such set is given by Eqs. (2-80) through (2-82) in the Seventh Edition of *Perry's Chemical Engineers' Handbook* (1997). These equations define *pseudoparameters*, so called because the defined values of  $T_{pc}$ ,  $P_{pc}$ , and  $\omega$  have no physical significance for the mixture.

The Lee-Kesler correlations provide reliable data for nonpolar and slightly polar gases; errors of less than 3 percent are likely. Larger errors can be expected in applications to highly polar and associating gases.

The quantum gases (e.g., hydrogen, helium, and neon) do not conform to the same corresponding-states behavior as do normal fluids. Prausnitz, Lichtenthaler, and de Azevedo [*Molecular Thermodynamics of Fluid-Phase Equilibria*, 3d ed., pp. 172–173, Prentice-Hall PTR, Upper Saddle River, N.J. (1999)] propose the use of temperature-dependent *effective* critical parameters. For hydrogen, the quantum gas most commonly found in chemical processing, the recommended equations are

$$\frac{T_c}{\text{K}} = \frac{43.6}{1 + 21.8/2.016T} \quad (\text{for H}_2) \quad (4-124)$$

$$\frac{P_c}{\text{bar}} = \frac{20.5}{1 + 44.2/2.016T} \quad (\text{for H}_2) \quad (4-125)$$

$$\frac{V_c}{\text{cm}^3 \text{mol}^{-1}} = \frac{51.5}{1 - 9.91/2.016T} \quad (\text{for H}_2) \quad (4-126)$$

where  $T$  is absolute temperature in kelvins. Use of these *effective* critical parameters for hydrogen requires the further specification that  $\omega = 0$ .

## OTHER PROPERTY FORMULATIONS

## LIQUID PHASE

Although residual properties have formal reality for liquids as well as for gases, their advantageous use as *small* corrections to ideal gas state properties is lost. Calculation of property changes for the liquid state are usually based on alternative forms of Eqs. (4-32) through (4-35), shown in Table 4-1. Useful here are the definitions of two liquid-phase properties—the volume expansivity  $\beta$  and the isothermal compressibility  $\kappa$ :

$$\beta \equiv \frac{1}{V} \left( \frac{\partial V}{\partial T} \right)_P \quad (4-127)$$

$$\kappa \equiv - \frac{1}{V} \left( \frac{\partial V}{\partial P} \right)_T \quad (4-128)$$

$$\text{For } V = f(T, P), \quad dV = \left( \frac{\partial V}{\partial T} \right)_P dT + \left( \frac{\partial V}{\partial P} \right)_T dP$$

This equation in combination with Eqs. (4-127) and (4-128) becomes

$$\frac{dV}{V} = \beta dT - \kappa dP \quad (4-129)$$

$$\text{If } V \text{ is constant,} \quad \left( \frac{\partial P}{\partial T} \right)_V = \frac{\beta}{\kappa} \quad (4-130)$$

Because liquid-phase isotherms of  $P$  versus  $V$  are very steep and closely spaced, both  $\beta$  and  $\kappa$  are small. Moreover (outside the critical region), they are weak functions of  $T$  and  $P$  and are often assumed constant at average values. Integration of Eq. (4-129) then gives

$$\ln \frac{V_2}{V_1} = \beta(T_2 - T_1) - \kappa(P_2 - P_1) \quad (4-131)$$

Substitution for the partial derivatives in Eqs. (4-32) through (4-35) by Eqs. (4-127) and (4-130) yields

$$dH = C_p dT + (1 - \beta T) V dP \quad (4-132)$$

$$dS = C_p \frac{dT}{T} - \beta V dP \quad (4-133)$$

$$dU = C_v dT + \left( \frac{\beta}{\kappa} T - P \right) dV \quad (4-134)$$

$$dS = \frac{C_v}{T} dT + \frac{\beta}{\kappa} dV \quad (4-135)$$

Integration of these equations is most common from the saturated-liquid state to the state of compressed liquid at constant  $T$ . For example, Eqs. (4-132) and (4-133) in integral form become

$$H = H^{\text{sat}} + \int_{P^{\text{sat}}}^P (1 - \beta T) V dP \quad (4-136)$$

$$S = S^{\text{sat}} - \int_{P^{\text{sat}}}^P \beta V dP \quad (4-137)$$

Again,  $\beta$  and  $V$  are weak functions of pressure for liquids, and are often assumed constant at the values for the saturated liquid at temperature  $T$ . An alternative treatment of  $V$  comes from Eq. (4-131), which for this application can be written

$$V = V^{\text{sat}} \exp[-\kappa(P - P^{\text{sat}})]$$

## LIQUID/VAPOR PHASE TRANSITION

The isothermal vaporization of a pure liquid results in a phase change from saturated liquid to saturated vapor at vapor pressure  $P^{\text{sat}}$ . The

treatment of this transition is facilitated by definition of property changes of vaporization  $\Delta M^{\text{lv}}$ :

$$\Delta M^{\text{lv}} \equiv M^{\text{v}} - M^{\text{l}} \quad (4-138)$$

where  $M^{\text{l}}$  and  $M^{\text{v}}$  are molar properties for states of saturated liquid and saturated vapor. Some experimental values of the enthalpy change of vaporization  $\Delta H^{\text{lv}}$ , usually called the latent heat of vaporization, are listed in Table 2-150.

The enthalpy change and entropy change of vaporization are directly related:

$$\Delta H^{\text{lv}} = T \Delta S^{\text{lv}} \quad (4-139)$$

This equation follows from Eq. (4-15), because vaporization at the vapor pressure  $P^{\text{sat}}$  occurs at constant  $T$ .

As shown by Smith, Van Ness, and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., p. 221, McGraw-Hill, New York (2005)] the heat of vaporization is directly related to the slope of the vapor-pressure curve.

$$\Delta H^{\text{lv}} = T \Delta V^{\text{lv}} \frac{dP^{\text{sat}}}{dT} \quad (4-140)$$

Known as the Clapeyron equation, this exact thermodynamic relation provides the connection between the properties of the liquid and vapor phases.

In application an empirical vapor pressure versus temperature relation is required. The simplest such equation is

$$\ln P^{\text{sat}} = A - \frac{B}{T} \quad (4-141)$$

where  $A$  and  $B$  are constants for a given chemical species. This equation approximates  $P^{\text{sat}}$  over its entire temperature range from triple point to critical point. It is also a sound basis for interpolation between reasonably spaced values of  $T$ . More satisfactory for general use is the Antoine equation

$$\ln P^{\text{sat}} = A - \frac{B}{T + C} \quad (4-142)$$

The Wagner equation is useful for accurate representation of vapor pressure data over a wide temperature range. It expresses the reduced vapor pressure as a function of reduced temperature

$$\ln P_r^{\text{sat}} = \frac{A\tau + B\tau^{1.5} + C\tau^3 + D\tau^6}{1 - \tau} \quad (4-143)$$

where

$$\tau \equiv 1 - T_r$$

and  $A$ ,  $B$ ,  $C$ , and  $D$  are constants. Values of the constants for either the Wagner equation or the Antoine equation are given for many species by Poling, Prausnitz, and O'Connell [*The Properties of Gases and Liquids*, 5th ed., App. A, McGraw-Hill, New York (2001)].

Latent heats of vaporization are functions of temperature, and experimental values at a particular temperature are often not available. Recourse is then made to approximate methods. *Trouton's rule* of 1884 provides a simple check on whether values calculated by other methods are reasonable:

$$\frac{\Delta H_n^{\text{lv}}}{RT_n} \sim 10$$

Here,  $T_n$  is the absolute temperature of the normal boiling point, and  $\Delta H_n^{\text{lv}}$  is the latent heat at this temperature. The units of  $\Delta H_n^{\text{lv}}$ ,  $R$ , and  $T_n$  must be chosen so that  $\Delta H_n^{\text{lv}}/RT_n$  is dimensionless.

A much more accurate equation is that of Riedel [*Chem. Ing. Tech.* 26: 679-683 (1954)]:

$$\frac{\Delta H_n^{\text{lv}}}{RT_n} = \frac{1.092(\ln P_c - 1.013)}{0.930 - T_r} \quad (4-144)$$

## 4-14 THERMODYNAMICS

where  $P_c$  is the critical pressure in bars and  $T_r$  is the reduced temperature at  $T_r$ . This equation provides reasonable approximations; errors rarely exceed 5 percent.

Estimates of the latent heat of vaporization of a pure liquid at any temperature from the known value at a single temperature may be based on an experimental value or on a value estimated by Eq. (4-144).

Watson's equation [*Ind. Eng. Chem.* **35**: 398–406 (1943)] has found wide acceptance:

$$\frac{\Delta H_{12}^{lg}}{\Delta H_1^{lg}} = \left( \frac{1 - T_{r2}}{1 - T_{r1}} \right)^{0.38} \quad (4-145)$$

This equation is simple and fairly accurate.

## THERMODYNAMICS OF FLOW PROCESSES

The thermodynamics of flow encompasses mass, energy, and entropy balances for open systems, i.e., for systems whose boundaries allow the inflow and outflow of fluids. The common measures of flow are as follows:

Mass flow rate  $\dot{m}$    molar flow rate  $\dot{n}$    volumetric flow rate  $q$    velocity  $u$   
 Also                     $\dot{m} = M\dot{n}$    and             $q = uA$

where  $M$  is molar mass. Mass flow rate is related to velocity by

$$\dot{m} = uA\rho \quad (4-146)$$

where  $A$  is the cross-sectional area of a conduit and  $\rho$  is mass density. If  $\rho$  is molar density, then this equation yields molar flow rate. Flow rates  $\dot{m}$ ,  $\dot{n}$ , and  $q$  measure quantity per unit of time. Although velocity  $u$  does not represent quantity of flow, it is an important design parameter.

### MASS, ENERGY, AND ENTROPY BALANCES FOR OPEN SYSTEMS

Mass and energy balances for an open system are written with respect to a region of space known as a *control volume*, bounded by an imaginary *control surface* that separates it from the surroundings. This surface may follow fixed walls or be arbitrarily placed; it may be rigid or flexible.

**Mass Balance for Open Systems** Because mass is conserved, the time rate of change of mass within the control volume equals the net rate of flow of mass into the control volume. The flow is positive when directed into the control volume and negative when directed out. The mass balance is expressed mathematically by

$$\frac{dm_{cv}}{dt} + \Delta(\dot{m})_{fs} = 0 \quad (4-147)$$

The operator  $\Delta$  signifies the difference between exit and entrance flows, and the subscript  $fs$  indicates that the term encompasses all flowing streams. When the mass flow rate  $\dot{m}$  is given by Eq. (4-146),

$$\frac{dm_{cv}}{dt} + \Delta(\rho uA)_{fs} = 0 \quad (4-148)$$

This form of the mass balance equation is often called the *continuity equation*. For the special case of *steady-state* flow, the control volume contains a constant mass of fluid, and the first term of Eq. (4-148) is zero.

**General Energy Balance** Because energy, like mass, is conserved, the time rate of change of energy within the control volume equals the net rate of energy transfer into the control volume. Streams flowing into and out of the control volume have associated with them energy in its internal, potential, and kinetic forms, and all contribute to the energy change of the system. Energy may also flow across the control surface as heat and work. Smith, Van Ness, and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., pp. 47–48, McGraw-Hill, New York (2005)] show that the general energy balance for flow processes is

$$\frac{d(mU)_{cv}}{dt} + \Delta \left[ \left( H + \frac{1}{2}u^2 + zg \right) \dot{m} \right]_{fs} = \dot{Q} + \dot{W} \quad (4-149)$$

The work rate  $\dot{W}$  may be of several forms. Most commonly there is shaft work  $\dot{W}_s$ . Work may be associated with expansion or contraction of the control volume, and there may be stirring work. The velocity  $u$  in the kinetic energy term is the bulk mean velocity as defined by the

equation  $u = \dot{m}/\rho A$ ;  $z$  is elevation above a datum level, and  $g$  is the local acceleration of gravity.

**Energy Balances for Steady-State Flow Processes** Flow processes for which the first term of Eq. (4-149) is zero are said to occur at *steady state*. As discussed with respect to the mass balance, this means that the mass of the system within the control volume is constant; it also means that no changes occur with time in the properties of the fluid within the control volume or at its entrances and exits. No expansion of the control volume is possible under these circumstances. The only work of the process is shaft work, and the general energy balance, Eq. (4-149), becomes

$$\Delta \left[ \left( H + \frac{1}{2}u^2 + zg \right) \dot{m} \right]_{fs} = \dot{Q} + \dot{W}_s \quad (4-150)$$

**Entropy Balance for Open Systems** An entropy balance differs from an energy balance in a very important way—*entropy is not conserved*. According to the second law, the entropy changes in the system and surroundings as the result of any process must be positive, with a limiting value of zero for a reversible process. Thus, the entropy changes resulting from the process sum not to zero, but to a positive quantity called the *entropy generation* term. The statement of balance, expressed as rates, is therefore

$$\left\{ \begin{array}{l} \text{Net rate of} \\ \text{change in} \\ \text{entropy of} \\ \text{flowing streams} \end{array} \right\} + \left\{ \begin{array}{l} \text{Time rate of} \\ \text{change of} \\ \text{entropy} \\ \text{in control} \\ \text{volume} \end{array} \right\} + \left\{ \begin{array}{l} \text{Time rate of} \\ \text{change of} \\ \text{entropy in} \\ \text{surroundings} \end{array} \right\} = \left\{ \begin{array}{l} \text{Total rate} \\ \text{of entropy} \\ \text{generation} \end{array} \right\}$$

The equivalent *equation of entropy balance* is

$$\Delta(S\dot{m})_{fs} + \frac{d(mS)_{cv}}{dt} + \frac{dS_{surr}}{dt} = \dot{S}_C \geq 0 \quad (4-151)$$

where  $\dot{S}_C$  is the entropy generation term. In accord with the second law, it must be positive, with zero as a limiting value. This equation is the general *rate* form of the entropy balance, applicable at any instant. The three terms on the left are the net rate of gain in entropy of the flowing streams, the time rate of change of the entropy of the fluid contained within the control volume, and the time rate of change of the entropy of the surroundings.

The entropy change of the surroundings results from heat transfer between system and surroundings. Let  $\dot{Q}_j$  represent the heat-transfer rate at a particular location on the control surface associated with a surroundings temperature  $T_{\sigma,j}$ . In accord with Eq. (4-3), the rate of entropy change in the surroundings as a result of this transfer is  $-\dot{Q}_j/T_{\sigma,j}$ . The minus sign converts  $\dot{Q}_j$ , defined with respect to the system, to a heat rate with respect to the surroundings. The third term in Eq. (4-151) is therefore the sum of all such quantities, and Eq. (4-151) can be written

$$\Delta(S\dot{m})_{fs} + \frac{d(mS)_{cv}}{dt} - \sum_j \frac{\dot{Q}_j}{T_{\sigma,j}} = \dot{S}_C \geq 0 \quad (4-152)$$

For any process, the two kinds of irreversibility are (1) those *internal* to the control volume and (2) those resulting from heat transfer across finite temperature differences that may exist between the

TABLE 4-3 Equations of Balance

| General equations of balance  | Balance equations for steady-flow processes   | Balance equations for single-stream steady-flow processes         |
|---|---|---|
| $\frac{dm_{cv}}{dt} + \Delta(\dot{m})_s = 0$ (4-147)  | $\Delta(\dot{m})_s = 0$ (4-153)   | $\dot{m}_1 = \dot{m}_2 = \dot{m}$ (4-154)                         |
| $\frac{d(mU)_{cv}}{dt} + \Delta\left[\left(H + \frac{1}{2}u^2 + zg\right)\dot{m}\right]_{fs} = \dot{Q} + \dot{W}$ (4-149) | $\Delta\left[\left(H + \frac{1}{2}u^2 + zg\right)\dot{m}\right]_{fs} = \dot{Q} + \dot{W}_s$ (4-150) | $\Delta H + \frac{\Delta u^2}{2} + g\Delta z = Q + W_s$ (4-155)   |
| $\frac{d(mS)_{cv}}{dt} + \Delta(S\dot{m})_s - \sum_j \frac{\dot{Q}_j}{T_{\sigma,j}} = \dot{S}_G \geq 0$ (4-152)           | $\Delta(S\dot{m})_s - \sum_j \frac{\dot{Q}_j}{T_{\sigma,j}} = \dot{S}_G \geq 0$ (4-156)             | $\Delta S - \sum_j \frac{Q_j}{T_{\sigma,j}} = S_G \geq 0$ (4-157) |

system and surroundings. In the limiting case where  $\dot{S}_G = 0$ , the process is *completely reversible*, implying that

- The process is internally reversible within the control volume.
- Heat transfer between the control volume and its surroundings is reversible.

**Summary of Equations of Balance for Open Systems** Only the most general equations of mass, energy, and entropy balance appear in the preceding sections. In each case important applications require less general versions. The most common restricted case is for steady flow processes, wherein the mass and thermodynamic properties of the fluid within the control volume are not time-dependent. A further simplification results when there is but one entrance and one exit to the control volume. In this event,  $\dot{m}$  is the same for both streams, and the equations may be divided through by this rate to put them on the basis of a unit amount of fluid flowing through the control volume. Summarized in Table 4-3 are the basic equations of balance and their important restricted forms.

**APPLICATIONS TO FLOW PROCESSES**

**Duct Flow of Compressible Fluids** Thermodynamics provides equations interrelating pressure changes, velocity, duct cross-sectional area, enthalpy, entropy, and specific volume within a flowing stream. Considered here is the adiabatic, steady-state, one-dimensional flow of a compressible fluid in the absence of shaft work and changes in potential energy. The appropriate energy balance is Eq. (4-155). With  $Q, W_s,$  and  $\Delta z$  all set equal to zero,

$$\Delta H + \frac{\Delta u^2}{2} = 0$$

In differential form,  $dH = -u du$  (4-158)

The continuity equation given by Eq. (4-148) here becomes  $d(\rho uA) = d(uA/V) = 0$ , whence

$$\frac{dV}{V} - \frac{du}{u} - \frac{dA}{A} = 0$$
 (4-159)

Smith, Abbott, and Van Ness [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., pp. 255–258, McGraw-Hill, New York (2005)] show that these basic equations in combination with Eq. (4-15) and other property relations yield two very general equations

$$V(1 - M^2) \frac{dP}{dx} + T\left(1 + \frac{\beta u^2}{C_p}\right) \frac{dS}{dx} - \frac{u^2}{A} \frac{dA}{dx} = 0$$
 (4-160)

$$u \frac{du}{dx} - T\left(\frac{\beta u^2/C_p + M^2}{1 - M^2}\right) \frac{dS}{dx} + \left(\frac{1}{1 - M^2}\right) \frac{u^2}{A} \frac{dA}{dx} = 0$$
 (4-161)

Mach number  $M$  is the ratio of the speed of fluid in the duct to the speed of sound in the fluid. The derivatives in these equations are rates of change with length as the fluid passes through a duct. Equation (4-160) relates the pressure derivative, and Eq. (4-161), the velocity derivative, to the entropy and area derivatives. According to

the second law, the irreversibilities of fluid friction in adiabatic flow cause an entropy increase in the fluid in the direction of flow. In the limit as the flow approaches reversibility, this increase approaches zero. In general, then,  $dS/dx \geq 0$ .

**Pipe Flow** For a pipe of constant cross-sectional area,  $dA/dx = 0$ , and Eqs. (4-160) and (4-161) reduce to

$$\frac{dp}{dx} = -\frac{T}{V} \left(\frac{1 + \beta u^2/C_p}{1 - M^2}\right) \frac{ds}{dx} \quad u \frac{du}{dx} = T \left(\frac{\beta u^2/C_p + M^2}{1 - M^2}\right) \frac{ds}{dx}$$

When flow is subsonic,  $M^2 < 1$ ; all terms on the right in these equations are then positive, and  $dP/dx < 0$  and  $du/dx > 0$ . Pressure therefore decreases and velocity increases in the direction of flow. The velocity increase is, however, limited, because these inequalities would reverse if the velocity were to become supersonic. This is not possible in a pipe of constant cross-sectional area, and the maximum fluid velocity obtainable is the speed of sound, reached at the *exit* of the pipe. Here,  $dS/dx$  reaches its limiting value of zero. For a discharge pressure low enough, the flow becomes sonic and lengthening the pipe does not alter this result; the mass rate of flow decreases so that the sonic velocity is still obtained at the outlet of the lengthened pipe.

According to the equations for supersonic pipe flow, pressure increases and velocity decreases in the direction of flow. However, this flow regime is unstable, and a supersonic stream entering a pipe of constant cross section undergoes a compression shock, the result of which is an abrupt and finite increase in pressure and decrease in velocity to a subsonic value.

**Nozzles** Nozzle flow is quite different from pipe flow. In a properly designed nozzle, its cross-sectional area changes with length in such a way as to make the flow nearly frictionless. The limit is reversible flow, for which the rate of entropy increase is zero. In this event  $dS/dx = 0$ , and Eqs. (4-160) and (4-161) become

$$\frac{dP}{dx} = \frac{u^2}{VA} \left(\frac{1}{1 - M^2}\right) \frac{dA}{dx} \quad \frac{du}{dx} = -\frac{u}{A} \left(\frac{1}{1 - M^2}\right) \frac{dA}{dx}$$

The characteristics of flow depend on whether the flow is subsonic ( $M < 1$ ) or supersonic ( $M > 1$ ). The possibilities are summarized in Table 4-4. Thus, for subsonic flow in a converging nozzle, the velocity increases and the pressure decreases as the cross-sectional area

TABLE 4-4 Nozzle Characteristics

|                 | Subsonic: $M < 1$ |           | Supersonic: $M > 1$ |           |
|-----------------|-------------------|-----------|---------------------|-----------|

## 4-16 THERMODYNAMICS

diminishes. The maximum possible fluid velocity is the speed of sound, reached at the exit. A converging subsonic nozzle can therefore deliver a constant flow rate into a region of variable pressure.

Supersonic velocities characterize the diverging section of a properly designed converging/diverging nozzle. Sonic velocity is reached at the throat, where  $dA/dx = 0$ , and a further increase in velocity and decrease in pressure require a diverging cross-sectional area to accommodate the increasing volume of flow. The pressure at the throat must be low enough for the velocity to become sonic. If this is not the case, the diverging section acts as a diffuser—the pressure rises and the velocity decreases in the conventional behavior of subsonic flow in a diverging section.

An analytical expression relating velocity to pressure in an isentropic nozzle is readily derived for an ideal gas with constant heat capacities. Combination of Eqs. (4-15) and (4-159) for isentropic flow gives

$$u du = -V dP$$

Integration, with nozzle entrance and exit conditions denoted by 1 and 2, yields

$$u_2^2 - u_1^2 = -2 \int_{P_1}^{P_2} V dP = \frac{2\gamma P_1 V_1}{\gamma - 1} \left[ 1 - \left( \frac{P_2}{P_1} \right)^{(\gamma-1)/\gamma} \right] \quad (4-162)$$

where the final term is obtained upon elimination of  $V$  by  $PV^\gamma = \text{const}$ , an equation valid for ideal gases with constant heat capacities. Here,  $\gamma \equiv C_p/C_v$ .

**Throttling Process** Fluid flowing through a restriction, such as an orifice, without appreciable change in kinetic or potential energy undergoes a finite pressure drop. This *throttling process* produces no shaft work, and in the absence of heat transfer, Eq. (4-155) reduces to  $\Delta H = 0$  or  $H_2 = H_1$ . The process therefore occurs at constant enthalpy.

The temperature of an ideal gas is not changed by a throttling process, because its enthalpy depends on temperature only. For most real gases at moderate conditions of  $T$  and  $P$ , a reduction in pressure at constant enthalpy results in a decrease in temperature, although the effect is usually small. Throttling of a wet vapor to a sufficiently low pressure causes the liquid to evaporate and the vapor to become superheated. This results in a considerable temperature drop because of the evaporation of liquid.

If a saturated liquid is throttled to a lower pressure, some of the liquid vaporizes or *flashes*, producing a mixture of saturated liquid and saturated vapor at the lower pressure. Again, the large temperature drop results from evaporation of liquid.

**Turbines (Expanders)** High-velocity streams from nozzles impinging on blades attached to a rotating shaft form a turbine (or expander) through which vapor or gas flows in a steady-state expansion process which converts internal energy of a high-pressure stream into shaft work. The motive force may be provided by steam (turbine) or by a high-pressure gas (expander).

In any properly designed turbine, heat transfer and changes in potential and kinetic energy are negligible. Equation (4-155) therefore reduces to

$$W_s = \Delta H = H_2 - H_1 \quad (4-163)$$

The rate form of this equation is

$$\dot{W}_s = \dot{m} \Delta H = \dot{m}(H_2 - H_1) \quad (4-164)$$

When inlet conditions  $T_1$  and  $P_1$  and discharge pressure  $P_2$  are known, the value of  $H_1$  is fixed. In Eq. (4-163) both  $H_2$  and  $W_s$  are unknown, and the energy balance alone does not allow their calculation. However, if the fluid expands *reversibly and adiabatically*, i.e., isentropically, in the turbine, then  $S_2 = S_1$ . This second equation establishes the final state of the fluid and allows calculation of  $H_2$ . Equation (4-164) then gives the isentropic work:

$$W_s(\text{isentropic}) = (\Delta H)_s \quad (4-165)$$

The absolute value  $|W_s(\text{isentropic})|$  is the *maximum* work that can be produced by an adiabatic turbine with given inlet conditions and given

**FIG. 4-2** Adiabatic expansion process in a turbine or expander. [Smith, Van Ness, and Abbott, *Introduction to Chemical Engineering Thermodynamics*, 7th ed., p. 269, McGraw-Hill, New York (2005).]

discharge pressure. Because the actual expansion process is irreversible, *turbine efficiency* is defined as

$$\eta \equiv \frac{W_s}{W_s(\text{isentropic})}$$

where  $W_s$  is the actual shaft work. By Eqs. (4-163) and (4-165),

$$\eta = \frac{\Delta H}{(\Delta H)_s} \quad (4-166)$$

Values of  $\eta$  usually range from 0.7 to 0.8.

The  $HS$  diagram of Fig. 4-2 compares the path of an actual expansion in a turbine with that of an isentropic expansion for the same intake conditions and the same discharge pressure. The isentropic path is the dashed vertical line from point 1 at intake pressure  $P_1$  to point 2' at  $P_2$ . The irreversible path (solid line) starts at point 1 and terminates at point 2 on the isobar for  $P_2$ . The process is adiabatic, and irreversibilities cause the path to be directed toward increasing entropy. The greater the irreversibility, the farther point 2 lies to the right on the  $P_2$  isobar, and the lower the value of  $\eta$ .

**Compression Processes** Compressors, pumps, fans, blowers, and vacuum pumps are all devices designed to bring about pressure increases. Their energy requirements for steady-state operation are of interest here. Compression of gases may be accomplished in rotating equipment (high-volume flow) or for high pressures in cylinders with reciprocating pistons. The energy equations are the same; indeed, based on the same assumptions, they are the same as for turbines or expanders. Thus, Eqs. (4-159) through (4-161) apply to adiabatic compression.

The isentropic work of compression, as given by Eq. (4-165), is the *minimum* shaft work required for compression of a gas from a given initial state to a given discharge pressure. A compressor efficiency is defined as

$$\eta \equiv \frac{W_s(\text{isentropic})}{W_s}$$

In view of Eqs. (4-163) and (4-165), this becomes

$$\eta \equiv \frac{(\Delta H)_s}{\Delta H} \quad (4-167)$$

Compressor efficiencies are usually in the range of 0.7 to 0.8.

The compression process is shown on an  $HS$  diagram in Fig. 4-3. The vertical dashed line rising from point 1 to point 2' represents the reversible adiabatic (isentropic) compression process from  $P_1$  to  $P_2$ .

**FIG. 4-3** Adiabatic compression process. [Smith, Van Ness, and Abbott, Introduction to Chemical Engineering Thermodynamics, 7th ed., p. 274, McGraw-Hill, New York (2005).]

The actual irreversible compression process follows the solid line from point 1 upward and to the right in the direction of increasing entropy, terminating at point 2. The more irreversible the process, the farther this point lies to the right on the  $P_2$  isobar, and the lower the efficiency  $\eta$  of the process.

Liquids are moved by pumps, usually by rotating equipment. The same equations apply to adiabatic pumps as to adiabatic compressors. Thus, Eqs. (4-163) through (4-165) and Eq. (4-167) are valid. However, application of Eq. (4-163) requires values of the enthalpy of compressed (subcooled) liquids, and these are seldom available. The fundamental property relation, Eq. (4-15), provides an alternative. For an isentropic process,

$$dH = V dP \quad (\text{constant } S)$$

Combining this with Eq. (4-165) yields

$$W_s(\text{isentropic}) = (\Delta H)_S = \int_{P_1}^{P_2} V dP$$

The usual assumption for liquids (at conditions well removed from the critical point) is that  $V$  is independent of  $P$ . Integration then gives

$$W_s(\text{isentropic}) = (\Delta H)_S = V(P_2 - P_1) \quad (4-168)$$

Also useful are Eqs. (4-132) and (4-133). Because temperature changes in the pumped fluid are very small and because the properties of liquids are insensitive to pressure (again at conditions not close to the critical point), these equations are usually integrated on the assumption that  $C_p$ ,  $V$ , and  $\beta$  are constant, usually at initial values. Thus, to a good approximation

$$\Delta H = C_p \Delta T + V(1 - \beta T) \Delta P \quad (4-169)$$

$$\Delta S = C_p \ln \frac{T_2}{T_1} - \beta V \Delta P \quad (4-170)$$

**Example 1: LNG Vaporization and Compression** A port facility for unloading liquefied natural gas (LNG) is under consideration. The LNG arrives by ship, stored as saturated liquid at 115 K and 1.325 bar, and is unloaded at the rate of 450 kg s<sup>-1</sup>. It is proposed to vaporize the LNG with heat discarded from a heat engine operating between 300 K, the temperature of atmospheric air, and 115 K, the temperature of the vaporizing LNG. The saturated-vapor LNG so produced is compressed adiabatically to 20 bar, using the work produced by the heat engine to supply part of the compression work. Estimate the work to be supplied from an external source.

For estimation purposes we need not be concerned with the design of the heat engine, but assume that a suitable engine can be built to deliver 30 percent of the work of a Carnot engine operating between the temperatures of 300 and 115 K. The equations that apply to Carnot engines can be found in any thermodynamics text.

$$\text{By the first law:} \quad |W| = |Q_H| - |Q_C|$$

$$\text{By the second law:} \quad \frac{|Q_H|}{|Q_C|} = \frac{T_H}{T_C}$$

$$\text{In combination:} \quad |W| = |Q_C| \left( \frac{T_H}{T_C} - 1 \right)$$

Here,  $|W|$  is the work produced by the Carnot engine;  $|Q_C|$  is the heat transferred at the cold temperature, i.e., to vaporize the LNG;  $T_H$  and  $T_C$  are the hot and cold temperatures of the heat reservoirs between which the heat engine operates, or 300 and 115 K, respectively. LNG is essentially pure methane, and enthalpy values from Table 2-281 of the Seventh Edition of *Perry's Chemical Engineers' Handbook* provide its heat of vaporization:

$$\Delta H^{lv} = H^v - H^l = 802.5 - 297.7 = 504.8 \text{ kJ kg}^{-1}$$

For a flow rate of 450 kg s<sup>-1</sup>,

$$|Q_C| = (450)(504.8) = 227,160 \text{ kJ s}^{-1}$$

The equation for work gives

$$|W| = (227,160) \left( \frac{300}{115} - 1 \right) = 3.654 \times 10^5 \text{ kJ s}^{-1} = 3.654 \times 10^5 \text{ kW}$$

This is the reversible work of a Carnot engine. The assumption is that the actual power produced is 30 percent of this, or  $1.096 \times 10^5$  kW.

The enthalpy and entropy of saturated vapor at 115 K and 1.325 bar are given in Table 2-281 of the Seventh Edition of *Perry's* as

$$H^v = 802.5 \text{ kJ kg}^{-1} \quad \text{and} \quad S^v = 9.436 \text{ kJ kg}^{-1} \text{ K}^{-1}$$

Isentropic compression of saturated vapor at 1.325 to 20 bar produces superheated vapor with an entropy of 9.436 kJ kg<sup>-1</sup> K<sup>-1</sup>. Interpolation in Table 2-282 at 20 bar yields an enthalpy of  $H = 1026.2$  kJ kg<sup>-1</sup> at 234.65 K. The enthalpy change of isentropic compression is then

$$\Delta H_S = 1026.2 - 802.5 = 223.7 \text{ kJ kg}^{-1}$$

For a compressor efficiency of 75 percent, the actual enthalpy change of compression is

$$\Delta H = \frac{\Delta H_S}{\eta} = \frac{223.7}{0.75} = 298.3 \text{ kJ kg}^{-1}$$

The actual enthalpy of superheated LNG at 20 bar is then

$$H = 802.5 + 298.3 = 1100.8 \text{ kJ kg}^{-1}$$

Interpolation in Table 2-282 of the Seventh Edition of *Perry's* indicates an actual temperature of 265.9 K for the compressed LNG, which is quite suitable for its entry into the distribution system.

The work of compression is

$$|W| = m \Delta H = (450 \text{ kg s}^{-1})(298.3 \text{ kJ kg}^{-1}) = 1.342 \times 10^5 \text{ kJ s}^{-1} = 1.342 \times 10^5 \text{ kW}$$

The estimated power which must be supplied from an external source is

$$\dot{W} = 1.342 \times 10^5 - 1.096 \times 10^5 = 24,600 \text{ kW}$$

## SYSTEMS OF VARIABLE COMPOSITION

The composition of a system may vary because the system is open or because of chemical reactions even in a closed system. The equations developed here apply regardless of the cause of composition changes.

### PARTIAL MOLAR PROPERTIES

For a homogeneous  $PVT$  system comprised of any number of chemical species, let symbol  $M$  represent the molar (or unit-mass) value of an

extensive thermodynamic property, say,  $U$ ,  $H$ ,  $S$ ,  $A$ , or  $G$ . A total-system property is then  $nM$ , where  $n = \sum_i n_i$  and  $i$  is the index identifying chemical species. One might expect the solution property  $M$  to be related solely to the properties  $M_i$  of the pure chemical species which comprise the solution. However, no such generally valid relation is known, and the connection must be established experimentally for every specific system.

Although the chemical species which make up a solution do not have their own individual properties, a solution property may be arbitrarily

## 4-18 THERMODYNAMICS

apportioned among the individual species. Once an apportioning recipe is adopted, the assigned property values are quite logically treated as though they were indeed properties of the individual species in solution, and reasoning on this basis leads to valid conclusions.

For a homogeneous  $PVT$  system, postulate 5 requires that

$$nM = \mathcal{M}(T, P, n_1, n_2, n_3, \dots)$$

The total differential of  $nM$  is therefore

$$d(nM) = \left[ \frac{\partial(nM)}{\partial T} \right]_{P, n} dT + \left[ \frac{\partial(nM)}{\partial P} \right]_{T, n} dP + \sum_i \left[ \frac{\partial(nM)}{\partial n_i} \right]_{T, P, n_j} dn_i$$

where subscript  $n$  indicates that all mole numbers  $n_i$  are held constant, and subscript  $n_j$  signifies that all mole numbers are held constant except the  $i$ th. This equation may also be written

$$d(nM) = n \left( \frac{\partial M}{\partial T} \right)_{P, x} dT + n \left( \frac{\partial M}{\partial P} \right)_{T, x} dP + \sum_i \left[ \frac{\partial(nM)}{\partial n_i} \right]_{T, P, n_j} dn_i$$

where subscript  $x$  indicates that all mole fractions are held constant. The derivatives in the summation are called *partial molar properties*. They are given the generic symbol  $\bar{M}_i$  and are defined by

$$\bar{M}_i \equiv \left[ \frac{\partial(nM)}{\partial n_i} \right]_{T, P, n_j} \quad (4-171)$$

The basis for calculation of partial properties from solution properties is provided by this equation. Moreover,

$$d(nM) = n \left( \frac{\partial M}{\partial T} \right)_{P, x} dT + n \left( \frac{\partial M}{\partial P} \right)_{T, x} dP + \sum_i \bar{M}_i dn_i \quad (4-172)$$

This equation, valid for any equilibrium phase, either closed or open, attributes changes in total property  $nM$  to changes in  $T$  and  $P$  and to mole-number changes resulting from mass transfer or chemical reaction.

The following are mathematical identities:

$$d(nM) = n dM + M dn \quad dn_i = d(x_i n) = x_i dn + n dx_i$$

Combining these expressions with Eq. (4-172) and collecting like terms give

$$\left[ dM - \left( \frac{\partial M}{\partial T} \right)_{P, x} dT - \left( \frac{\partial M}{\partial P} \right)_{T, x} dP - \sum_i \bar{M}_i dx_i \right] n + \left[ M - \sum_i \bar{M}_i x_i \right] dn = 0$$

Because  $n$  and  $dn$  are independent and arbitrary, the terms in brackets must separately be zero, whence

$$dM = \left( \frac{\partial M}{\partial T} \right)_{P, x} dT + \left( \frac{\partial M}{\partial P} \right)_{T, x} dP + \sum_i \bar{M}_i dx_i \quad (4-173)$$

and

$$M = \sum_i x_i \bar{M}_i \quad (4-174)$$

The first of these equations is merely a special case of Eq. (4-172); however, Eq. (4-174) is a vital new relation. Known as the *summability equation*, it provides for the calculation of solution properties from partial properties, a purpose opposite to that of Eq. (4-171). Thus a solution property apportioned according to the recipe of Eq. (4-171) may be recovered simply by adding the properties attributed to the individual species, each weighted by its mole fraction in solution. The equations for partial molar properties are valid also for partial specific properties, in which case  $m$  replaces  $n$  and  $\{x_i\}$  are mass fractions. Equation (4-171) applied to the definitions of Eqs. (4-8) through (4-10) yields the partial-property relations

$$\bar{H}_i = \bar{U}_i + P\bar{V}_i \quad \bar{A}_i = \bar{U}_i - T\bar{S}_i \quad \bar{G}_i = \bar{H}_i - T\bar{S}_i$$

These equations illustrate the parallelism that exists between the equations for a constant-composition solution and those for the corresponding partial properties. This parallelism exists whenever the

solution properties in the parent equation are related linearly (in the algebraic sense).

**Gibbs-Duhem Equation** Differentiation of Eq. (4-174) yields

$$dM = \sum_i x_i d\bar{M}_i + \sum_i \bar{M}_i dx_i$$

Because this equation and Eq. (4-173) are both valid in general, their right sides can be equated, yielding

$$\left( \frac{\partial M}{\partial T} \right)_{P, x} dT + \left( \frac{\partial M}{\partial P} \right)_{T, x} dP - \sum_i x_i d\bar{M}_i = 0 \quad (4-175)$$

This general result, the Gibbs-Duhem equation, imposes a constraint on how the partial properties of any phase may vary with temperature, pressure, and composition. For the special case where  $T$  and  $P$  are constant,

$$\sum_i x_i d\bar{M}_i = 0 \quad (\text{constant } T, P) \quad (4-176)$$

Symbol  $M$  may represent the molar value of any extensive thermodynamic property, say,  $V$ ,  $U$ ,  $H$ ,  $S$ , or  $G$ . When  $M \equiv H$ , the derivatives  $(\partial H/\partial H)_P$  and  $(\partial H/\partial P)_T$  are given by Eqs. (4-28) and (4-29), and Eqs. (4-173), (4-174), and (4-175) specialize to

$$dH = C_P dT + \left[ V - T \left( \frac{\partial V}{\partial T} \right)_{P, x} \right] dP + \sum_i \bar{H}_i dx_i \quad (4-177)$$

$$H = \sum_i x_i \bar{H}_i \quad (4-178)$$

$$C_P dT + \left[ V - T \left( \frac{\partial V}{\partial T} \right)_{P, x} \right] dP - \sum_i x_i d\bar{H}_i = 0 \quad (4-179)$$

Similar equations are readily derived when  $M$  takes on other identities.

Equation (4-171), which defines a partial molar property, provides a general means by which partial-property values may be determined. However, for a *binary* solution an alternative method is useful. Equation (4-174) for a binary solution is

$$M = x_1 \bar{M}_1 + x_2 \bar{M}_2$$

Moreover, the Gibbs-Duhem equation for a solution at given  $T$  and  $P$ , Eq. (4-176), becomes

$$x_1 d\bar{M}_1 + x_2 d\bar{M}_2 = 0$$

These two equations combine to yield

$$\bar{M}_1 = M + x_2 \frac{dM}{dx_1} \quad (4-180a)$$

$$\bar{M}_2 = M - x_1 \frac{dM}{dx_1} \quad (4-180b)$$

Thus for a binary solution, the partial properties are given directly as functions of composition for given  $T$  and  $P$ . For multicomponent solutions such calculations are complex, and direct use of Eq. (4-171) is appropriate.

**Partial Molar Equation-of-State Parameters** The parameters in equations of state as applied to mixtures are related to composition by mixing rules. For the second virial coefficient

$$B = \sum_i \sum_j y_i y_j B_{ij} \quad (4-60)$$

The partial molar second virial coefficient is by definition

$$\bar{B}_i \equiv \left[ \frac{\partial(nB)}{\partial n_i} \right]_{T, n_j} \quad (4-181)$$

Because  $B$  is independent of  $P$ , this is in accord with Eq. (4-171). These two equations lead through derivation to useful expressions for  $\bar{B}_i$ , as shown in detail by Van Ness and Abbott [*Classical Thermodynamics of Nonelectrolyte Solutions: With Applications to Phase*

*Equilibria*, pp. 137–140, McGraw-Hill, New York (1982)]. The simplest result is

$$\bar{B} = 2 \sum_k y_k B_{ki} - B \quad (4-182)$$

An analogous expression follows from Eq. (4-114) for parameter  $a$  in the generic cubic equation of state given by Eqs. (4-100), (4-103), and (4-104):

$$\bar{a}_i = 2 \sum_k y_k a_{ki} - a \quad (4-183)$$

This expression is independent of the combining rule [e.g., Eq. (4-114)] used for  $a_{ki}$ . For the *linear* mixing rule of Eq. (4-113) for  $b$ , the result of derivation is simply  $b_i = b_i$ .

**Partial Molar Gibbs Energy** Implicit in Eq. (4-13) is the relation

$$\mu_i = \left[ \frac{\partial(nG)}{\partial n_i} \right]_{T,P,n_j}$$

Comparison with Eq. (4-171) indicates the following identity:

$$\mu_i = \bar{G}_i \quad (4-184)$$

The reciprocity relation for an exact differential applied to Eq. (4-13) produces not only the Maxwell relation, Eq. (4-21), but also two other useful equations:

$$\left( \frac{\partial \mu_i}{\partial P} \right)_{T,n} = \left[ \frac{\partial(nV)}{\partial n_i} \right]_{T,P,n_j} = \bar{V}_i \quad (4-185)$$

$$\left( \frac{\partial \mu_i}{\partial T} \right)_{P,n} = - \left[ \frac{\partial(nS)}{\partial n_i} \right]_{T,P,n_j} = -\bar{S}_i \quad (4-186)$$

Because  $\mu = f(T, P)$ ,

$$d\mu_i = d\bar{G}_i = \left( \frac{\partial \mu_i}{\partial T} \right)_{P,n} dT + \left( \frac{\partial \mu_i}{\partial P} \right)_{T,n} dP$$

$$\text{and} \quad d\bar{G}_i = -\bar{S}_i dT + \bar{V}_i dP \quad (4-187)$$

Similarly, in view of Eqs. (4-14), (4-15), and (4-16),

$$d\bar{U}_i = T d\bar{S}_i - P d\bar{V}_i \quad (4-188)$$

$$d\bar{H}_i = T d\bar{S}_i + \bar{V}_i dP \quad (4-189)$$

$$d\bar{A}_i = -\bar{S}_i dT - P d\bar{V}_i \quad (4-190)$$

These equations again illustrate the fact that for every equation providing a *linear* relation among the thermodynamic properties of a *constant-composition* solution there exists a parallel relationship for the partial properties of the species in solution.

The following equation is a mathematical identity:

$$d \left( \frac{nG}{RT} \right) \equiv \frac{1}{RT} d(nG) - \frac{nG}{RT^2} dT$$

Substitution for  $d(nG)$  by Eq. (4-13), with  $\mu_i = \bar{G}_i$ , and for  $G$  by Eq. (4-10) gives, after algebraic reduction,

$$d \left( \frac{nG}{RT} \right) = \frac{nV}{RT} dP - \frac{nH}{RT^2} dT + \sum_i \frac{\bar{G}_i}{RT} dn_i \quad (4-191)$$

This result is a useful alternative to the fundamental property relation given by Eq. (4-13). All terms in this equation have units of moles; moreover, the enthalpy rather than the entropy appears on the right side.

## SOLUTION THERMODYNAMICS

**Ideal Gas Mixture Model** The ideal gas mixture model is useful because it is molecularly based, is analytically simple, is realistic in the

limit of zero pressure, and provides a conceptual basis upon which to build the structure of solution thermodynamics. Smith, Van Ness, and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., pp. 391–394, McGraw-Hill, New York (2005)] develop the following property relations for the ideal gas model.

$$\bar{V}_i^{ig} = V_i^{ig} = \frac{RT}{P} \quad (4-192)$$

Because the enthalpy is independent of pressure,

$$\bar{H}_i^{ig} = H_i^{ig} \quad (4-193)$$

where  $S_i^{ig}$  is evaluated at the *mixture*  $T$  and  $P$ . The entropy of an ideal gas *does* depend on pressure, and here

$$\bar{S}_i^{ig} = S_i^{ig} - R \ln y_i \quad (4-194)$$

where  $S_i^{ig}$  is evaluated at the mixture  $T$  and  $P$ .

From the definition of the Gibbs energy,  $\bar{G}_i^{ig} = \bar{H}_i^{ig} - T\bar{S}_i^{ig}$ . In combination with Eqs. (4-193) and (4-194), this becomes

$$\bar{G}_i^{ig} = H_i^{ig} - TS_i^{ig} + RT \ln y_i$$

$$\text{or} \quad \mu_i^{ig} \equiv \bar{G}_i^{ig} = G_i^{ig} + RT \ln y_i \quad (4-195)$$

Elimination of  $G_i^{ig}$  from this equation is accomplished through Eq. (4-17), written for pure species  $i$  as an ideal gas:

$$dG_i^{ig} = V_i^{ig} dP = \frac{RT}{P} dP = RT d \ln P \quad (\text{constant } T)$$

$$\text{Integration gives} \quad G_i^{ig} = \Gamma_i(T) + RT \ln P \quad (4-196)$$

where integration constant  $\Gamma_i(T)$  is a function of temperature only. Equation (4-195) now becomes

$$\mu_i^{ig} = \bar{G}_i^{ig} = \Gamma_i(T) + RT \ln(y_i P) \quad (4-197)$$

$$\text{By Eq. (4-172)} \quad G^{id} = \sum_i y_i \Gamma_i(T) + RT \sum_i \ln(y_i P) \quad (4-198)$$

A dimensional ambiguity is apparent with Eqs. (4-196) through (4-198) in that  $P$  has units, whereas  $\ln P$  must be dimensionless. In practice this is of no consequence, because only *differences* in Gibbs energy appear, along with *ratios* of the quantities with units of pressure in the arguments of the logarithm. Consistency in the units of pressure is, of course, required.

**Fugacity and Fugacity Coefficient** The chemical potential  $\mu_i$  plays a vital role in both phase and chemical reaction equilibria. However, the chemical potential exhibits certain unfortunate characteristics that discourage its use in the solution of practical problems. The Gibbs energy, and hence  $\mu_i$ , is defined in relation to the internal energy and entropy, both primitive quantities for which absolute values are unknown. Moreover,  $\mu_i$  approaches negative infinity when either  $P$  or  $y_i$  approaches zero. While these characteristics do not preclude the use of chemical potentials, the application of equilibrium criteria is facilitated by introduction of the *fugacity*, a quantity that takes the place of  $\mu_i$  but that does not exhibit its less desirable characteristics.

The origin of the fugacity concept resides in Eq. (4-196), an equation valid only for pure species  $i$  in the ideal gas state. For a *real* fluid, an analogous equation is written as

$$G_i \equiv \Gamma_i(T) + RT \ln f_i \quad (4-199)$$

in which a new property  $f_i$  replaces the pressure  $P$ . This equation serves as a partial definition of the *fugacity*  $f_i$ .

Subtraction of Eq. (4-196) from Eq. (4-199), both written for the same temperature and pressure, gives

$$G_i - G_i^{ig} = RT \ln \frac{f_i}{P}$$

## 4-20 THERMODYNAMICS

According to the definition of Eq. (4-40),  $G_i - G_i^{ig}$  is the residual Gibbs energy  $G_i^R$ . The dimensionless ratio  $f_i/P$  is another new property called the *fugacity coefficient*  $\phi_i$ . Thus,

$$G_i^R = RT \ln \phi_i \quad (4-200)$$

where

$$\phi_i \equiv \frac{f_i}{P} \quad (4-201)$$

The definition of fugacity is completed by setting the ideal gas state fugacity of pure species  $i$  equal to its pressure,  $f_i^{ig} = P$ . Thus for the special case of an ideal gas,  $G_i^R = 0$ ,  $\phi_i = 1$ , and Eq. (4-196) is recovered from Eq. (4-199).

The definition of the fugacity of a species in solution is parallel to the definition of the pure-species fugacity. An equation analogous to the ideal gas expression, Eq. (4-197), is written for species  $i$  in a fluid mixture

$$\mu_i \equiv \Gamma_i(T) + RT \ln \hat{f}_i \quad (4-202)$$

where the partial pressure  $y_i P$  is replaced by  $\hat{f}_i$ , the fugacity of species  $i$  in solution. Because it is not a partial property, it is identified by a circumflex rather than an overbar.

Subtracting Eq. (4-197) from Eq. (4-202), both written for the same temperature, pressure, and composition, yields

$$\mu_i - \mu_i^{ig} = RT \ln \frac{\hat{f}_i}{y_i P}$$

The residual Gibbs energy of a mixture is defined by  $G^R \equiv G - G^{ig}$ , and the analogous definition of a partial molar residual Gibbs energy is  $G_i^R \equiv G_i - G_i^{ig} = \mu_i - \mu_i^{ig}$ . Therefore

$$\overline{G}_i^R = RT \ln \hat{\phi}_i \quad (4-203)$$

where by definition

$$\hat{\phi}_i \equiv \frac{\hat{f}_i}{y_i P} \quad (4-204)$$

The dimensionless ratio  $\hat{\phi}_i$  is called the *fugacity coefficient of species  $i$  in solution*.

Equation (4-203) is the analog of Eq. (4-200), which relates  $\phi_i$  to  $G_i^R$ . For an ideal gas,  $G_i^R$  is necessarily zero; therefore  $\hat{\phi}_i^{ig} = 1$  and  $\hat{f}_i^{ig} = y_i P$ . Thus the fugacity of species  $i$  in an ideal gas mixture is equal to its partial pressure.

**Evaluation of Fugacity Coefficients** Combining Eq. (4-200) with Eq. (4-45) gives

$$\ln \phi = \frac{G^R}{RT} = \int_0^P (Z - 1) \frac{dP}{P} \quad (4-205)$$

Subscript  $i$  is omitted, with the understanding that  $\phi$  here is for a pure species. Clearly, all correlations for  $G^R/RT$  are also correlations for  $\ln \phi$ .

Equation (4-200) with Eqs. (4-48) and (4-73) yields

$$\ln \phi = \int_0^{P_r} (Z - 1) \frac{dP_r}{P_r} = (B^0 + \omega B^1) \frac{P_r}{T_r} \quad (4-206)$$

This equation, used in conjunction with Eqs. (4-77) and (4-78), provides a useful generalized correlation for the fugacity coefficients of pure species.

A more comprehensive generalized correlation results from Eqs. (4-200) and (4-116):

$$\ln \phi = \int_0^{P_r} (Z^0 - 1) \frac{dP_r}{P_r} + \omega \int_0^{P_r} Z^1 \frac{dP_r}{P_r}$$

An alternative form is  $\ln \phi = \ln \phi^0 + \omega \ln \phi^1$  (4-207)

where  $\ln \phi^0 \equiv \int_0^{P_r} (Z^0 - 1) \frac{dP_r}{P_r}$  and  $\ln \phi^1 \equiv \int_0^{P_r} Z^1 \frac{dP_r}{P_r}$

By Eq. (4-207),  $\phi = (\phi^0)(\phi^1)^\omega$  (4-208)

Correlations may therefore be presented for  $\phi^0$  and  $\phi^1$ , as was done by Lee and Kesler [AIChE J. 21: 510-527 (1975)].

**Ideal Solution Model** The ideal gas model is useful as a standard of comparison for real gas behavior. This is formalized through residual properties. The *ideal solution* is similarly useful as a standard to which real solution behavior may be compared.

The partial molar Gibbs energy or chemical potential of species  $i$  in an ideal gas mixture is given by Eq. (4-195), written as

$$\mu_i^{ig} = \overline{G}_i^{ig} = G_i^{ig}(T, P) + RT \ln y_i$$

This equation takes on new meaning when  $G_i^{ig}(T, P)$  is replaced by  $G_i(T, P)$ , the Gibbs energy of pure species  $i$  in its *real physical state* of gas, liquid, or solid at the mixture  $T$  and  $P$ . The ideal solution is therefore *defined* as one for which

$$\mu_i^{id} = \overline{G}_i^{id} \equiv G_i(T, P) + RT \ln x_i \quad (4-209)$$

where superscript *id* denotes an ideal solution property and  $x_i$  represents the mole fraction because application is usually to liquids.

This equation is the basis for development of expressions for all other thermodynamic properties of an ideal solution. Equations (4-185) and (4-186), applied to an ideal solution with  $\mu_i$  replaced by  $\overline{G}_i$ , are written as

$$\overline{V}_i^{id} = \left( \frac{\partial \overline{G}_i^{id}}{\partial P} \right)_{T,x} \quad \text{and} \quad \overline{S}_i^{id} = - \left( \frac{\partial \overline{G}_i^{id}}{\partial T} \right)_{P,x}$$

Differentiation of Eq. (4-209) yields

$$\left( \frac{\partial \overline{G}_i^{id}}{\partial P} \right)_{T,x} = \left( \frac{\partial G_i}{\partial P} \right)_T \quad \text{and} \quad \left( \frac{\partial \overline{G}_i^{id}}{\partial T} \right)_{P,x} = \left( \frac{\partial G_i}{\partial T} \right)_P + R \ln x_i$$

Equation (4-17) implies that

$$\left( \frac{\partial G_i}{\partial P} \right)_T = V_i \quad \text{and} \quad \left( \frac{\partial G_i}{\partial T} \right)_P = -S_i$$

In combination these sets of equations provide

$$\overline{V}_i^{id} = V_i \quad (4-210)$$

and

$$\overline{S}_i^{id} = S_i - R \ln x_i \quad (4-211)$$

Because  $\overline{H}_i^{id} = \overline{G}_i^{id} + T\overline{S}_i^{id}$ , substitutions by Eqs. (4-209) and (4-211) yield

$$\overline{H}_i^{id} = H_i \quad (4-212)$$

The summability relation, Eq. (4-174), written for the special case of an ideal solution, may be applied to Eqs. (4-209) through (4-212):

$$G^{id} = \sum_i x_i G_i + RT \sum_i x_i \ln x_i \quad (4-213)$$

$$V^{id} = \sum_i x_i V_i \quad (4-214)$$

$$S^{id} = \sum_i x_i S_i - R \sum_i x_i \ln x_i \quad (4-215)$$

$$H^{id} = \sum_i x_i H_i \quad (4-216)$$

A simple equation for the fugacity of a species in an ideal solution follows from Eq. (4-209). For the special case of species  $i$  in an ideal solution, Eq. (4-202) becomes

$$\mu_i^{id} = \overline{G}_i^{id} = \Gamma_i(T) + RT \ln \hat{f}_i^{id}$$

When this equation and Eq. (4-199) are combined with Eq. (4-209),  $\Gamma_i(T)$  is eliminated, and the resulting expression reduces to

$$\hat{f}_i^{id} = x_i f_i \quad (4-217)$$

This equation, known as the *Lewis-Randall rule*, shows that the fugacity of each species in an ideal solution is proportional to its mole fraction; the proportionality constant is the fugacity of *pure* species  $i$  in the same physical state as the solution and at the same  $T$  and  $P$ . Division of both sides of Eq. (4-217) by  $x_i P$  and substitution of  $\hat{\phi}_i^{id}$  for  $\hat{f}_i^{id}/x_i P$  [Eq. (4-204)] and of  $\phi_i$  for  $f_i/P$  [Eq. (4-201)] give the alternative form

$$\hat{\phi}_i^{id} = \phi_i \quad (4-218)$$

Thus the fugacity coefficient of species  $i$  in an ideal solution equals the fugacity coefficient of *pure* species  $i$  in the same physical state as the solution and at the same  $T$  and  $P$ .

Ideal solution behavior is often approximated by solutions comprised of molecules not too different in size and of the same chemical nature. Thus, a mixture of isomers conforms very closely to ideal solution behavior. So do mixtures of adjacent members of a homologous series.

**Excess Properties** An excess property  $M^E$  is defined as the difference between the actual property value of a solution and the value it would have as an ideal solution at the same  $T$ ,  $P$ , and composition. Thus,

$$M^E \equiv M - M^{id} \quad (4-219)$$

where  $M$  represents the molar (or unit-mass) value of any extensive thermodynamic property (say,  $V$ ,  $U$ ,  $H$ ,  $S$ ,  $G$ ). This definition is analogous to the definition of a residual property as given by Eq. (4-40). However, excess properties have no meaning for pure species, whereas residual properties exist for pure species as well as for mixtures. Partial molar excess properties  $\bar{M}_i^E$  are defined analogously:

$$\bar{M}_i^E \equiv \bar{M}_i - \bar{M}_i^{id} \quad (4-220)$$

Of particular interest is the partial molar excess Gibbs energy. Equation (4-202) may be written as

$$\bar{G}_i = \Gamma_i(T) + RT \ln \hat{f}_i$$

In accord with Eq. (4-217) for an ideal solution, this becomes

$$\bar{G}_i^{id} = \Gamma_i(T) + RT \ln x_i f_i$$

By difference

$$\bar{G}_i - \bar{G}_i^{id} = RT \ln \frac{\hat{f}_i}{x_i f_i}$$

The left side is the partial excess Gibbs energy  $\bar{G}_i^E$ ; the dimensionless ratio  $\hat{f}_i/x_i f_i$  on the right is the *activity coefficient of species  $i$  in solution*, given the symbol  $\gamma_i$  and *by definition*,

$$\gamma_i \equiv \frac{\hat{f}_i}{x_i f_i} \quad (4-221)$$

Thus,

$$\bar{G}_i^E = RT \ln \gamma_i \quad (4-222)$$

Comparison with Eq. (4-203) shows that Eq. (4-222) relates  $\gamma_i$  to  $\bar{G}_i^E$  exactly as Eq. (4-203) relates  $\hat{\phi}_i$  to  $\bar{G}_i^R$ . For an ideal solution,  $\bar{G}_i^E = 0$ , and therefore  $\gamma_i = 1$ .

**Property Changes of Mixing** A property change of mixing is defined by

$$\Delta M \equiv M - \sum_i x_i M_i \quad (4-223)$$

where  $M$  represents a molar thermodynamic property of a homogeneous solution and  $M_i$  is the molar property of pure species  $i$  at the  $T$  and  $P$  of the solution and in the same physical state. Applications are usually to liquids.

Each of Eqs. (4-213) through (4-216) is an expression for an ideal solution property, and each may be combined with the defining equation for an excess property [Eq. (4-219)], yielding the equations of the first column of Table 4-5. In view of Eq. (4-223) these may be written as shown in the second column of Table 4-5, where  $\Delta G$ ,  $\Delta V$ ,

$\Delta S$ , and  $\Delta H$  are the Gibbs energy change of mixing, the volume change of mixing, the entropy change of mixing, and the enthalpy change of mixing. For an ideal solution, each excess property is zero, and for this special case the equations reduce to those shown in the third column of Table 4-5.

Property changes of mixing and excess properties are easily calculated one from the other. The most common property changes of mixing are the volume change of mixing  $\Delta V$  and the enthalpy change of mixing  $\Delta H$ , commonly called the *heat of mixing*. These properties are identical to the corresponding excess properties. Moreover, they are directly measurable, providing an experimental entry into the network of equations of solution thermodynamics.

## FUNDAMENTAL PROPERTY RELATIONS BASED ON THE GIBBS ENERGY

Of the four fundamental property relations shown in the second column of Table 4-1, only Eq. (4-13) has as its special or canonical variables  $T$ ,  $P$ , and  $\{n_i\}$ . It is therefore the basis for extension to several useful supplementary thermodynamic properties. Indeed an alternative form has been developed as Eq. (4-191). These equations are the first two entries in the upper left quadrant of Table 4-6, which is now to be filled out with important derived relationships.

**Fundamental Residual-Property Relation** Equation (4-191) is general and may be written for the special case of an ideal gas

$$d\left(\frac{nG^{ig}}{RT}\right) = \frac{nV^{ig}}{RT} dP - \frac{nH^{ig}}{RT^2} dT + \sum_i \frac{\bar{G}_i^{ig}}{RT} dn_i$$

Subtraction of this equation from Eq. (4-191) gives

$$d\left(\frac{nG^R}{RT}\right) = \frac{nV^R}{RT} dP - \frac{nH^R}{RT^2} dT + \sum_i \frac{\bar{G}_i^R}{RT} dn_i \quad (4-236)$$

where the definitions  $G^R \equiv G - G^{ig}$  and  $\bar{G}_i^R \equiv \bar{G}_i - \bar{G}_i^{ig}$  have been imposed. Equation (4-236) is the *fundamental residual-property relation*. An alternative form follows by introduction of the fugacity coefficient given by Eq. (4-203). The result is listed as Eq. (4-237) in the upper left quadrant of Table 4-6.

Limited forms of this equation are particularly useful. Division by  $dP$  and restriction to constant  $T$  and composition lead to

$$\frac{V^R}{RT} = \left[ \frac{\partial(G^R/RT)}{\partial P} \right]_{T,x} \quad (4-238)$$

Similarly, the result of division by  $dT$  and restriction to constant  $P$  and composition is

$$\frac{H^R}{RT} = -T \left[ \frac{\partial(G^R/RT)}{\partial T} \right]_{P,x} \quad (4-239)$$

Also implicit in Eq. (4-237) is the relation

$$\ln \hat{\phi}_i = \left[ \frac{\partial(nG^R/RT)}{\partial n_i} \right]_{T,P,n_j} \quad (4-240)$$

This equation demonstrates that  $\ln \hat{\phi}_i$  is a partial property with respect to  $G^R/RT$ . The summability relation therefore applies, and

$$\frac{G^R}{RT} = \sum_i x_i \ln \hat{\phi}_i \quad (4-241)$$

| Equations for partial molar properties (constant composition)   | Gibbs-Duhem equations   |
| $d\bar{G}_i = d\mu_i = \bar{V}_i dP - \bar{S}_i dT$ (4-256)   | $V dP - S dT = \sum_i x_i d\mu_i$ (4-260)   |
| $d\left(\frac{\bar{G}_i}{RT}\right) = d\left(\frac{\mu_i}{RT}\right) = \frac{\bar{V}_i}{RT} dP - \frac{\bar{H}_i}{RT^2} dT$ (4-257) | $\frac{V}{RT} dP - \frac{H}{RT^2} dT = \sum_i x_i d\left(\frac{\bar{G}_i}{RT}\right)$ (4-261) |
| $d\left(\frac{\bar{G}_i^R}{RT}\right) = d \ln \hat{\phi}_i = \frac{\bar{V}_i^R}{RT} dP - \frac{\bar{H}_i^R}{RT^2} dT$ (4-258)       | $\frac{V^R}{RT} dP - \frac{H^R}{RT^2} dT = \sum_i x_i d \ln \hat{\phi}_i$ (4-262)             |
| $d\left(\frac{\bar{G}_i^E}{RT}\right) = d \ln \gamma_i = \frac{\bar{V}_i^E}{RT} dP - \frac{\bar{H}_i^E}{RT^2} dT$ (4-259)           | $\frac{V^E}{RT} dP - \frac{H^E}{RT^2} dT = \sum_i x_i d \ln \gamma_i$ (4-263)                 |

Application of Eq. (4-240) to an expression giving  $G^R$  as a function of composition yields an equation for  $\ln \hat{\phi}_i$ . In the simplest case of a gas mixture for which the virial equation [Eq. (4-67)] is appropriate, Eq. (4-69) provides the relation

$$\frac{nG^R}{RT} = \frac{P}{RT} (nB)$$

Differentiation in accord with Eqs. (4-240) and (4-181) yields

$$\ln \hat{\phi}_i = \frac{P}{RT} \bar{B}_i \quad (4-242)$$

where  $\bar{B}_i$  is given by Eq. (4-182). For a binary system these equations reduce to

$$\ln \hat{\phi}_1 = \frac{P}{RT} (B_{11} + y_2^2 \delta_{12}) \quad (4-243a)$$

$$\ln \hat{\phi}_2 = \frac{P}{RT} (B_{22} + y_1^2 \delta_{12}) \quad (4-243b)$$

where  $\delta_{12} \equiv 2B_{12} - B_{11} - B_{22}$

For the special case of pure species  $i$ , these equations reduce to

$$\ln \phi_i = \frac{P}{RT} B_{ii} \quad (4-244)$$

For the generic cubic equation of state [Eqs. (4-104)],  $G^R/RT$  is given by Eq. (4-109), which in view of Eq. (4-200) for a pure species becomes

$$\ln \phi_i = Z_i - 1 - \ln(Z_i - \beta_i) - q_i I_i \quad (4-245)$$

For species  $i$  in solution Smith, Van Ness, and Abbott [Introduction to Chemical Engineering Thermodynamics, 7th ed., pp. 562-563, McGraw-Hill, New York (2005)] show that

$$\ln \hat{\phi}_i = \frac{\bar{b}_i}{b} (Z - 1) - \ln(Z - \beta) - \bar{q}_i I \quad (4-246)$$

Symbols without subscripts represent mixture properties, and  $I$  is given by Eq. (4-112).

**Fundamental Excess-Property Relation** Equations for excess properties are developed in much the same way as those for residual properties. For the special case of an ideal solution, Eq. (4-191) becomes

$$d\left(\frac{nG^{id}}{RT}\right) = \frac{nV^{id}}{RT} dP - \frac{nH^{id}}{RT^2} dT + \sum_i \frac{\bar{G}_i^{id}}{RT} dn_i$$

Subtraction of this equation from Eq. (4-191) yields

$$d\left(\frac{nG^E}{RT}\right) = \frac{nV^E}{RT} dP - \frac{nH^E}{RT^2} dT + \sum_i \frac{\bar{G}_i^E}{RT} dn_i \quad (4-247)$$

where the definitions  $G^E \equiv G - G^{id}$  and  $\bar{G}_i^E \equiv \bar{G}_i - \bar{G}_i^{id}$  have been imposed. Equation (4-247) is the *fundamental excess-property relation*. An alternative form follows by introduction of the activity coefficient as given by Eq. (4-222). This result is listed as Eq. (4-248) in the upper left quadrant of Table 4-6.

The following equations are in complete analogy to those for residual properties.

$$\frac{V^E}{RT} = \left[ \frac{\partial(G^E/RT)}{\partial P} \right]_{T,x} \quad (4-249)$$

$$\frac{H^E}{RT} = -T \left[ \frac{\partial(G^E/RT)}{\partial T} \right]_{P,x} \quad (4-250)$$

$$\ln \gamma_i = \left[ \frac{\partial(nG^E/RT)}{\partial n_i} \right]_{T,P,n_j} \quad (4-251)$$

This last equation demonstrates that  $\ln \gamma_i$  is a partial property with respect to  $G^E/RT$ , implying also the validity of the summability relation

$$\frac{G^E}{RT} = \sum_i x_i \ln \gamma_i \quad (4-252)$$

The equations of the upper left quadrant of Table 4-6 reduce to those of the upper right quadrant for  $n = 1$  and  $dn_i = 0$ . Each equation in the upper left quadrant has a partial-property analog, as shown in the lower left quadrant. Each equation of the upper left quadrant is a special case of Eq. (4-172) and therefore has associated with it a Gibbs-Duhem equation of the form of Eq. (4-173). These are shown in the lower right quadrant. The equations of Table 4-6 store an enormous amount of information, but they are so general that their direct

application is seldom appropriate. However, by inspection one can write a vast array of relations valid for particular applications. For example, one sees immediately from Eqs. (4-258) and (4-259) that

$$\left(\frac{\partial \ln \hat{\phi}_i}{\partial P}\right)_{T,x} = \frac{\bar{V}_i^R}{RT} \quad (4-264)$$

$$\left(\frac{\partial \ln \hat{\phi}_i}{\partial T}\right)_{P,x} = -\frac{\bar{H}_i^R}{RT^2} \quad (4-265)$$

$$\left(\frac{\partial \ln \gamma_i}{\partial P}\right)_{T,x} = \frac{\bar{V}_i^E}{RT} \quad (4-266)$$

$$\left(\frac{\partial \ln \gamma_i}{\partial T}\right)_{P,x} = -\frac{\bar{H}_i^E}{RT^2} \quad (4-267)$$

## MODELS FOR THE EXCESS GIBBS ENERGY

Excess properties find application in the treatment of liquid solutions. Of primary importance for engineering calculations is the excess Gibbs energy  $G^E$ , because its canonical variables are  $T$ ,  $P$ , and composition, the variables usually specified or sought in design calculations. Knowing  $G^E$  as a function of  $T$ ,  $P$ , and composition, one can in principle compute from it all other excess properties.

The excess volume for liquid mixtures is usually small, and in accord with Eq. (4-249) the pressure dependence of  $G^E$  is usually ignored. Thus, engineering efforts to model  $G^E$  center on representing its composition and temperature dependence. For binary systems at constant  $T$ ,  $G^E$  becomes a function of just  $x_1$ , and the quantity most conveniently represented by an equation is  $G^E/x_1x_2RT$ . The simplest procedure is to express this quantity as a power series in  $x_1$ :

$$\frac{G^E}{x_1x_2RT} = a + bx_1 + cx_1^2 + \dots \quad (\text{constant } T)$$

An equivalent power series with certain advantages is the *Redlich-Kister expansion* [Redlich, Kister, and Turnquist, *Chem. Eng. Progr. Symp. Ser. No. 2*, **48**: 49–61 (1952)]:

$$\frac{G^E}{x_1x_2RT} = A + B(x_1 - x_2) + C(x_1 - x_2)^2 + \dots$$

In application, different truncations of this expansion are appropriate, and for each truncation specific expressions for  $\ln \gamma_1$  and  $\ln \gamma_2$  result from application of Eq. (4-251). When all parameters are zero,  $G^E/RT = 0$ , and the solution is ideal. If  $B = C = \dots = 0$ , then

$$\frac{G^E}{x_1x_2RT} = A$$

where  $A$  is a constant for a given temperature. The corresponding equations for  $\ln \gamma_1$  and  $\ln \gamma_2$  are

$$\ln \gamma_1 = Ax_2^2 \quad (4-268a)$$

$$\ln \gamma_2 = Ax_1^2 \quad (4-268b)$$

The symmetric nature of these relations is evident. The infinite dilution values of the activity coefficients are  $\ln \gamma_1^\infty = \ln \gamma_2^\infty = A$ .

If  $C = \dots = 0$ , then

$$\frac{G^E}{x_1x_2RT} = A + B(x_1 - x_2) = A + B(2x_1 - 1)$$

and in this case  $G^E/x_1x_2RT$  is linear in  $x_1$ . The substitutions  $A + B = A_{21}$  and  $A - B = A_{12}$  transform this expression to the *Margules equation*:

$$\frac{G^E}{x_1x_2RT} = A_{21}x_1 + A_{12}x_2 \quad (4-269)$$

Application of Eq. (4-251) yields

$$\ln \gamma_1 = x_2^2 [A_{12} + 2(A_{21} - A_{12})x_1] \quad (4-270a)$$

$$\ln \gamma_2 = x_1^2 [A_{21} + 2(A_{12} - A_{21})x_2] \quad (4-270b)$$

When  $x_1 = 0$ ,  $\ln \gamma_1^\infty = A_{12}$ ; when  $x_2 = 0$ ,  $\ln \gamma_2^\infty = A_{21}$ .

An alternative equation is obtained when the reciprocal quantity  $x_1x_2RT/G^E$  is expressed as a linear function of  $x_1$ :

$$\frac{x_1x_2}{G^E/RT} = A' + B'(x_1 - x_2) = A' + B'(2x_1 - 1)$$

This may also be written as

$$\frac{x_1x_2}{G^E/RT} = A'(x_1 + x_2) + B'(x_1 - x_2) = (A' + B')x_1 + (A' - B')x_2$$

The substitutions  $A' + B' = 1/A'_{21}$  and  $A' - B' = 1/A'_{12}$  ultimately produce

$$\frac{G^E}{x_1x_2RT} = \frac{A'_{12}A'_{21}}{A'_{21}x_1 + A'_{12}x_2} \quad (4-271)$$

The activity coefficients implied by this equation are given by

$$\ln \gamma_1 = A'_{12} \left(1 + \frac{A'_{12}x_1}{A'_{21}x_2}\right)^{-2} \quad (4-272a)$$

$$\ln \gamma_2 = A'_{21} \left(1 + \frac{A'_{21}x_2}{A'_{12}x_1}\right)^{-2} \quad (4-272b)$$

These are the *van Laar equations*. When  $x_1 = 0$ ,  $\ln \gamma_1^\infty = A'_{12}$ ; when  $x_2 = 0$ ,  $\ln \gamma_2^\infty = A'_{21}$ .

The Redlich-Kister expansion, the Margules equations, and the van Laar equations are all special cases of a very general treatment based on rational functions, i.e., on equations for  $G^E$  given by ratios of polynomials [Van Ness and Abbott, *Classical Thermodynamics of Nonelectrolyte Solutions: With Applications to Phase Equilibria*, Sec. 5-7, McGraw-Hill, New York (1982)]. Although providing great flexibility in the fitting of VLE data for binary systems, they are without theoretical foundation, with no basis in theory for their extension to multi-component systems. Nor do they incorporate an explicit temperature dependence for the parameters.

Theoretical developments in the molecular thermodynamics of liquid solution behavior are often based on the concept of *local composition*, presumed to account for the short-range order and nonrandom molecular orientations resulting from differences in molecular size and intermolecular forces. Introduced by G. M. Wilson [*J. Am. Chem. Soc.* **86**: 127–130 (1964)] with the publication of a model for  $G^E$ , this concept prompted the development of alternative local composition models, most notably the NRTL (Non-Random Two-Liquid) equation of Renon and Prausnitz [*AIChE J.* **14**: 135–144 (1968)] and the UNIQUAC (UNIversal QUAsi-Chemical) equation of Abrams and Prausnitz [*AIChE J.* **21**: 116–128 (1975)].

The Wilson equation, like the Margules and van Laar equations, contains just two parameters for a binary system ( $\Lambda_{12}$  and  $\Lambda_{21}$ ) and is written as

$$\frac{G^E}{RT} = -x_1 \ln(x_1 + x_2\Lambda_{12}) - x_2 \ln(x_2 + x_1\Lambda_{21}) \quad (4-273)$$

$$\ln \gamma_1 = -\ln(x_1 + x_2\Lambda_{12}) + x_2 \left( \frac{\Lambda_{12}}{x_1 + x_2\Lambda_{12}} - \frac{\Lambda_{21}}{x_2 + x_1\Lambda_{21}} \right) \quad (4-274a)$$

$$\ln \gamma_2 = -\ln(x_2 + x_1\Lambda_{21}) - x_1 \left( \frac{\Lambda_{12}}{x_1 + x_2\Lambda_{12}} - \frac{\Lambda_{21}}{x_2 + x_1\Lambda_{21}} \right) \quad (4-274b)$$

At infinite dilution,

$$\ln \gamma_1^\infty = -\ln \Lambda_{12} + 1 - \Lambda_{21} \quad \ln \gamma_2^\infty = -\ln \Lambda_{21} + 1 - \Lambda_{12}$$

Both  $\Lambda_{12}$  and  $\Lambda_{21}$  must be positive numbers.

## 4-24 THERMODYNAMICS

The NRTL equation contains three parameters for a binary system and is written as

$$\frac{G^E}{x_1 x_2 RT} = \frac{G_{21} \tau_{21}}{x_1 + x_2 G_{21}} + \frac{G_{12} \tau_{12}}{x_2 + x_1 G_{12}} \quad (4-275)$$

$$\ln \gamma_1 = x_2^2 \left[ \tau_{21} \left( \frac{G_{21}}{x_1 + x_2 G_{21}} \right)^2 + \frac{G_{12} \tau_{12}}{(x_2 + x_1 G_{12})^2} \right] \quad (4-276a)$$

$$\ln \gamma_2 = x_1^2 \left[ \tau_{12} \left( \frac{G_{12}}{x_2 + x_1 G_{12}} \right)^2 + \frac{G_{21} \tau_{21}}{(x_1 + x_2 G_{21})^2} \right] \quad (4-276b)$$

Here  $G_{12} = \exp(-\alpha \tau_{12})$      $G_{21} = \exp(-\alpha \tau_{21})$

and  $\tau_{12} = \frac{b_{12}}{RT}$      $\tau_{21} = \frac{b_{21}}{RT}$

where  $\alpha$ ,  $b_{12}$ , and  $b_{21}$ , parameters specific to a particular pair of species, are independent of composition and temperature. The infinite dilution values of the activity coefficients are

$$\ln \gamma_1^\infty = \tau_{21} + \tau_{12} \exp(-\alpha \tau_{12}) \quad \ln \gamma_2^\infty = \tau_{12} + \tau_{21} \exp(-\alpha \tau_{21})$$

The local composition models have limited flexibility in the fitting of data, but they are adequate for most engineering purposes. Moreover, they are implicitly generalizable to multicomponent systems without the introduction of any parameters beyond those required to describe the constituent binary systems. For example, the Wilson equation for multicomponent systems is written as

$$\frac{G^E}{RT} = -\sum_i x_i \ln \left( \sum_j x_j \Lambda_{ij} \right) \quad (4-277)$$

and 
$$\ln \gamma_i = 1 - \ln \left( \sum_j x_j \Lambda_{ij} \right) - \sum_k \frac{x_k \Lambda_{ki}}{\sum_j x_j \Lambda_{kj}} \quad (4-278)$$

where  $\Lambda_{ij} = 1$  for  $i = j$ , etc. All indices in these equations refer to the same species, and all summations are over *all* species. For each  $ij$  pair there are two parameters, because  $\Lambda_{ij} \neq \Lambda_{ji}$ . For example, in a ternary system the three possible  $ij$  pairs are associated with the parameters  $\Lambda_{12}, \Lambda_{21}; \Lambda_{13}, \Lambda_{31};$  and  $\Lambda_{23}, \Lambda_{32}$ .

The temperature dependence of the parameters is given by

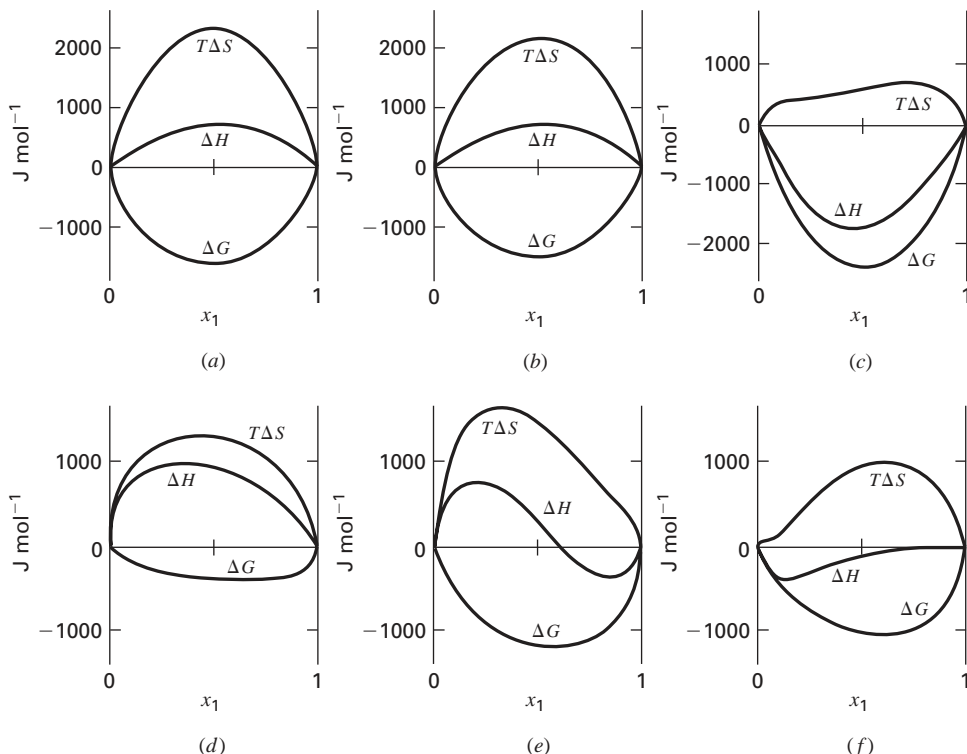

$$\Lambda_{ij} = \frac{V_j}{V_i} \exp \frac{-a_{ij}}{RT} \quad i \neq j \quad (4-279)$$

where  $V_j$  and  $V_i$  are the molar volumes of pure liquids  $j$  and  $i$  and  $a_{ij}$  is a constant independent of composition and temperature. Molar volumes  $V_j$  and  $V_i$ , themselves weak functions of temperature, form ratios that in practice may be taken as independent of  $T$ , and are usually evaluated at or near 25°C.

The Wilson parameters  $\Lambda_{ij}$  and NRTL parameters  $G_{ij}$  inherit a Boltzmann-type  $T$  dependence from the origins of the expressions for  $G^E$ , but it is only approximate. Computations of properties sensitive to this dependence (e.g., heats of mixing and liquid/liquid solubility) are in general only qualitatively correct. However, all parameters are found from data for binary (in contrast to multicomponent) systems, and this makes parameter determination for the local composition models a task of manageable proportions.

The UNIQUAC equation treats  $g \equiv G^E/RT$  as made up of two additive parts, a *combinatorial* term  $g^C$ , accounting for molecular size and shape differences, and a *residual* term  $g^R$  (not a residual property), accounting for molecular interactions:

$$g = g^C + g^R \quad (4-280)$$

**FIG. 4-4** Property changes of mixing at 50°C for six binary liquid systems: (a) chloroform(1)/n-heptane(2); (b) acetone(1)/methanol(2); (c) acetone(1)/chloroform(2); (d) ethanol(1)/n-heptane(2); (e) ethanol(1)/chloroform(2); (f) ethanol(1)/water(2). [Smith, Van Ness, and Abbott, Introduction to Chemical Engineering Thermodynamics, 7th ed., p. 455, McGraw-Hill, New York (2005).]

Function  $g^C$  contains pure-species parameters only, whereas function  $g^R$  incorporates two *binary* parameters for each pair of molecules. For a multicomponent system,

$$g^C = \sum_i x_i \ln \frac{\Phi_i}{x_i} + 5 \sum_i q_i x_i \ln \frac{\theta_i}{\Phi_i} \quad (4-281)$$

$$g^R = - \sum_i q_i x_i \ln \left( \sum_j \theta_j \tau_{ji} \right) \quad (4-282)$$

where

$$\Phi_i \equiv \frac{x_i r_i}{\sum_j x_j r_j} \quad (4-283)$$

and

$$\theta_i \equiv \frac{x_i q_i}{\sum_j x_j q_j} \quad (4-284)$$

Subscript  $i$  identifies species, and  $j$  is a dummy index; all summations are over all species. Note that  $\tau_{ii} \neq \tau_{jj}$ ; however, when  $i=j$ , then  $\tau_{ii} = \tau_{jj} = 1$ . In these equations  $r_i$  (a relative molecular volume) and  $q_i$  (a relative molecular surface area) are pure-species parameters. The influence of temperature on  $g$  enters through the interaction parameters  $\tau_{ji}$  of Eq. (4-282), which are temperature-dependent:

$$\tau_{ji} = \exp \frac{-(u_{ji} - u_{ii})}{RT} \quad (4-285)$$

Parameters for the UNIQUAC equation are therefore values of  $u_{ji} - u_{ii}$ .

An expression for  $\ln \gamma_i$  is found by application of Eq. (4-251) to the UNIQUAC equation for  $g$  [Eqs. (4-280) through (4-282)]. The result is given by the following equations:

$$\ln \gamma_i = \ln \gamma_i^C + \ln \gamma_i^R \quad (4-286)$$

$$\ln \gamma_i^C = 1 - J_i + \ln J_i - 5q_i \left( 1 - \frac{J_i}{L_i} + \ln \frac{J_i}{L_i} \right) \quad (4-287)$$

$$\ln \gamma_i^R = q_i \left( 1 - \ln s_i - \sum_j \theta_j \frac{\tau_{ij}}{s_j} \right) \quad (4-288)$$

where in addition to Eqs. (4-284) and (4-285),

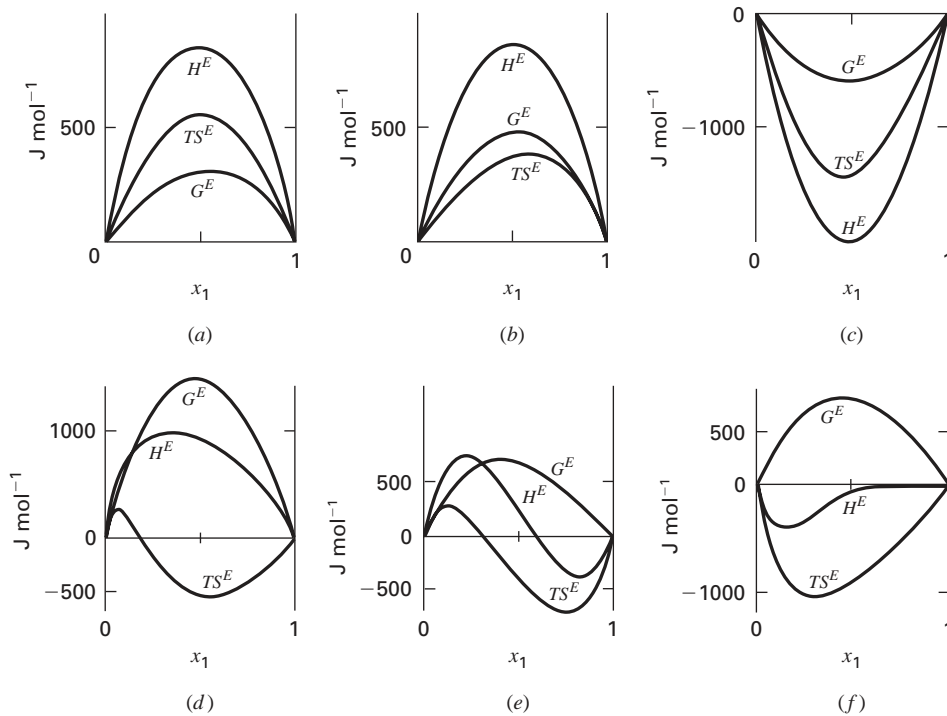

$$J_i = \frac{r_i}{\sum_j r_j x_j} \quad (4-289)$$

$$L_i = \frac{q_i}{\sum_j q_j x_j} \quad (4-290)$$

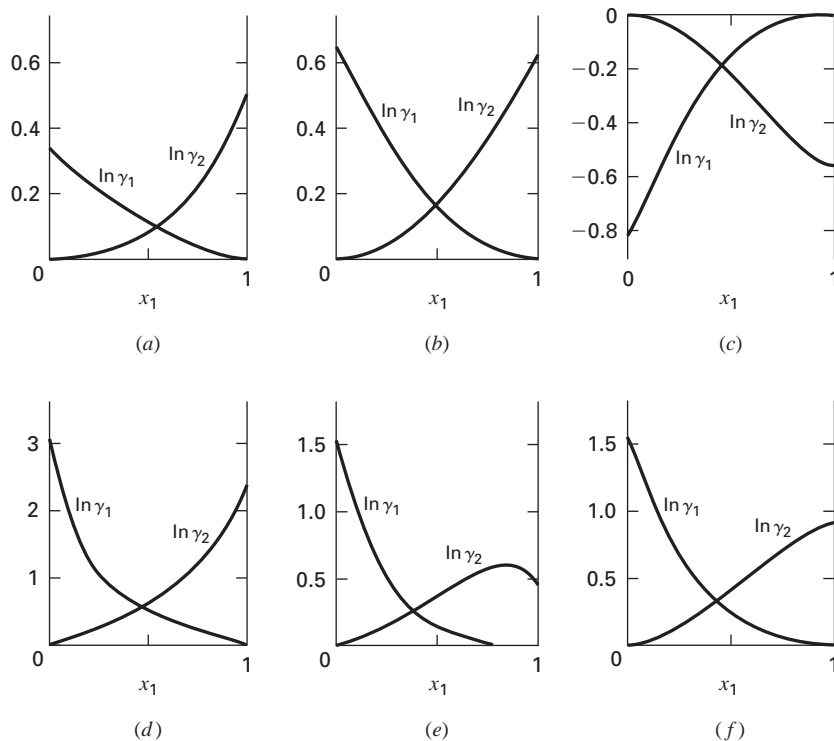

$$s_i = \sum_l \theta_l \tau_{li} \quad (4-291)$$

Again subscript  $i$  identifies species, and  $j$  and  $l$  are dummy indices.

Values for the parameters of the commonly used models for the excess Gibbs energy are given by Gmehling, Onken, and Arlt [*Vapor-Liquid Equilibrium Data Collection*, Chemistry Data Series, vol. 1, parts 1-8, DECHEMA, Frankfurt/Main (1974-1990)].

**FIG. 4-5** Excess properties at 50°C for six binary liquid systems: (a) chloroform(1)/*n*-heptane(2); (b) acetone(1)/methanol(2); (c) acetone(1)/chloroform(2); (d) ethanol(1)/*n*-heptane(2); (e) ethanol(1)/chloroform(2); (f) ethanol(1)/water(2). [Smith, Van Ness, and Abbott, *Introduction to Chemical Engineering Thermodynamics*, 7th ed., p. 420, McGraw-Hill, New York (2005).]

**FIG. 4-6** Activity coefficients at 50°C for six binary liquid systems: (a) chloroform(1)/n-heptane(2); (b) acetone(1)/methanol(2); (c) acetone(1)/chloroform(2); (d) ethanol(1)/n-heptane(2); (e) ethanol(1)/chloroform(2); (f) ethanol(1)/water(2). [Smith, Van Ness, and Abbott, Introduction to Chemical Engineering Thermodynamics, 7th ed., p. 445, McGraw-Hill, New York (2005).]

**Behavior of Binary Liquid Solutions** Property changes of mixing and excess properties find greatest application in the description of liquid mixtures at low reduced temperatures, i.e., at temperatures well below the critical temperature of each constituent species. The properties of interest to the chemical engineer are  $V^E$  ( $\equiv \Delta V$ ),  $H^E$  ( $\equiv \Delta H$ ),  $S^E$ ,  $\Delta S$ ,  $G^E$ , and  $\Delta G$ . The activity coefficient is also of special importance because of its application in phase equilibrium calculations.

The volume change of mixing ( $V^E = \Delta V$ ), the heat of mixing ( $H^E = \Delta H$ ), and the excess Gibbs energy  $G^E$  are experimentally accessible,  $\Delta V$  and  $\Delta H$  by direct measurement and  $G^E$  (or  $\ln \gamma_i$ ) indirectly by reduction of vapor/liquid equilibrium data. Knowledge of  $H^E$  and

$G^E$  allows calculation of  $S^E$  by Eq. (4-10), written for excess properties as

$$S^E = \frac{H^E - G^E}{T} \quad (4-292)$$

with  $\Delta S$  then given by Eq. (4-230).

Figure 4-4 displays plots of  $\Delta H$ ,  $\Delta S$ , and  $\Delta G$  as functions of composition for six binary solutions at 50°C. The corresponding excess properties are shown in Fig. 4-5; the activity coefficients, derived from Eq. (4-251), appear in Fig. 4-6. The properties shown here are insensitive to pressure and for practical purposes represent solution properties at 50°C and low pressure ( $P \approx 1$  bar).

## EQUILIBRIUM

### CRITERIA

The equations developed in preceding sections are for *PVT* systems in states of internal equilibrium. The criteria for internal thermal and mechanical equilibrium simply require uniformity of temperature and pressure throughout the system. The criteria for phase and chemical reaction equilibria are less obvious.

If a closed *PVT* system of uniform  $T$  and  $P$ , either homogeneous or heterogeneous, is in thermal and mechanical equilibrium with its surroundings, but is not at internal equilibrium with respect to mass transfer or chemical reaction, then changes in the system are irreversible and necessarily bring the system closer to an equilibrium state. The first and second laws written for the entire system are

$$dU^t = dQ + dW \quad dS^t \geq \frac{dQ}{T}$$

$$\text{Combination gives} \quad dU^t - dW - TdS^t \leq 0$$

Because mechanical equilibrium is assumed,  $dW = -PdV^t$ , whence

$$dU^t + PdV^t - TdS^t \leq 0$$

The inequality applies to all incremental changes toward the equilibrium state, whereas the equality holds at the equilibrium state where change is reversible.

Constraints put on this expression produce alternative criteria for the directions of irreversible processes and for the condition of equilibrium. For example,  $dU_{S^t, V^t} \leq 0$ . Particularly important is fixing  $T$  and  $P$ ; this produces

$$d(U^t + PV^t - TS^t)_{T,P} \leq 0 \quad \text{or} \quad dG_{T,P}^t \leq 0$$

This expression shows that all irreversible processes occurring at constant  $T$  and  $P$  proceed in a direction such that the total Gibbs energy of the system decreases. Thus the equilibrium state of a closed system is the state with the minimum total Gibbs energy attainable at the given  $T$  and  $P$ . At the equilibrium state, differential variations may occur in the system at constant  $T$  and  $P$  without producing a change in  $G^t$ . This is the meaning of the equilibrium criterion

$$dG_{T,P}^t = 0 \quad (4-293)$$

This equation may be applied to a closed, nonreactive, two-phase system. Each phase taken separately is an *open* system, capable of exchanging mass with the other; Eq. (4-13) is written for each phase:

$$d(nG)' = -(nS)' dT + (nV)' dP + \sum_i \mu_i' dn_i'$$

$$d(nG)'' = -(nS)'' dT + (nV)'' dP + \sum_i \mu_i'' dn_i''$$

where the primes and double primes denote the two phases; the presumption is that  $T$  and  $P$  are uniform throughout the two phases. The change in the Gibbs energy of the two-phase system is the sum of these equations. When each total-system property is expressed by an equation of the form  $nM = (nM)' + (nM)''$ , this sum is given by

$$d(nG) = (nV)dP - (nS)dT + \sum_i \mu_i' dn_i' + \sum_i \mu_i'' dn_i''$$

If the two-phase system is at equilibrium, then application of Eq. (4-293) yields

$$dG_{T,P}^t = d(nG)_{T,P} = \sum_i \mu_i' dn_i' + \sum_i \mu_i'' dn_i'' = 0$$

The system is closed and without chemical reaction; material balances therefore require that  $dn_i'' = -dn_i'$ , reducing the preceding equation to

$$\sum_i (\mu_i' - \mu_i'') dn_i' = 0$$

Because the  $dn_i'$  are independent and arbitrary, it follows that  $\mu_i' = \mu_i''$ . This is the criterion of two-phase equilibrium. It is readily generalized to multiple phases by successive application to pairs of phases. The general result is

$$\mu_i' = \mu_i'' = \mu_i''' = \dots \quad (4-294)$$

Substitution for each  $\mu_i$  by Eq. (4-202) produces the equivalent result:

$$\hat{f}_i' = \hat{f}_i'' = \hat{f}_i''' = \dots \quad (4-295)$$

These are the criteria of phase equilibrium applied in the solution of practical problems.

For the case of equilibrium with respect to chemical reaction within a single-phase closed system, combination of Eqs. (4-13) and (4-293) leads immediately to

$$\sum_i \mu_i dn_i = 0 \quad (4-296)$$

For a system in which both phase and chemical reaction equilibrium prevail, the criteria of Eqs. (4-295) and (4-296) are superimposed.

## PHASE RULE

The *intensive* state of a *PVT* system is established when its temperature and pressure and the compositions of all phases are fixed. However, for equilibrium states not all these variables are independent, and fixing a limited number of them automatically establishes the others. This number of independent variables is given by the phase rule, and it is called the *number of degrees of freedom* of the system. It is the number of variables that may be arbitrarily specified and that must be so specified in order to fix the *intensive* state of a system at equilibrium. This number is the difference between the number of variables needed to characterize the system and the number of equations that may be written connecting these variables.

For a system containing  $N$  chemical species distributed at equilibrium among  $\pi$  phases, the phase rule variables are  $T$  and  $P$ , presumed uniform throughout the system, and  $N - 1$  mole fractions in each

phase. The number of these variables is  $2 + (N - 1)\pi$ . The masses of the phases are not phase rule variables, because they have nothing to do with the intensive state of the system.

The equilibrium equations that may be written express chemical potentials or fugacities as functions of  $T$ ,  $P$ , and the phase compositions, the phase rule variables:

1. Equation (4-295) for each species, giving  $(\pi - 1)N$  phase equilibrium equations

2. Equation (4-296) for each independent chemical reaction, giving  $r$  equations

The total number of independent equations is therefore  $(\pi - 1)N + r$ . Because the degrees of freedom of the system  $F$  is the difference between the number of variables and the number of equations,

$$F = 2 + (N - 1)\pi - (\pi - 1)N - r$$

$$\text{or} \quad F = 2 - \pi + N - r \quad (4-297)$$

The number of independent chemical reactions  $r$  can be determined as follows:

1. Write *formation* reactions from the elements for each chemical compound present in the system.

2. Combine these reaction equations so as to eliminate from the set all elements not present as elements in the system. A systematic procedure is to select one equation and combine it with each of the other equations of the set so as to eliminate a particular element. This usually reduces the set by one equation for each element eliminated, although two or more elements may be simultaneously eliminated.

The resulting set of  $r$  equations is a complete set of independent reactions. More than one such set is often possible, but all sets number  $r$  and are equivalent.

### Example 2: Application of the Phase Rule

a. For a system of two miscible nonreacting species in vapor/liquid equilibrium,

$$F = 2 - \pi + N - r = 2 - 2 + 2 - 0 = 2$$

The 2 degrees of freedom for this system may be satisfied by setting  $T$  and  $P$ , or  $T$  and  $y_1$ , or  $P$  and  $x_1$ , or  $x_1$  and  $y_1$ , etc., at fixed values. Thus for equilibrium at a particular  $T$  and  $P$ , this state (if possible at all) exists only at one liquid and one vapor composition. Once the 2 degrees of freedom are used up, no further specification is possible that would restrict the phase rule variables. For example, one cannot *in addition* require that the system form an azeotrope (assuming this is possible), for this requires  $x_1 = y_1$ , an equation not taken into account in the derivation of the phase rule. Thus the requirement that the system form an azeotrope imposes a special constraint, making  $F = 1$ .

b. For a gaseous system consisting of CO, CO<sub>2</sub>, H<sub>2</sub>, H<sub>2</sub>O, and CH<sub>4</sub> in chemical reaction equilibrium,

$$F = 2 - \pi + N - r = 2 - 1 + 5 - 2 = 4$$

The value of  $r = 2$  is found from the formation reactions:

Systematic elimination of C and O<sub>2</sub> from this set of chemical equations reduces the set to two. Three possible pairs of equations may result, depending on how the combination of equations is effected. Any *pair* of the following three equations represents a complete set of independent reactions, and all pairs are equivalent.

The result,  $F = 4$ , means that one is free to specify, for example,  $T$ ,  $P$ , and two mole fractions in an equilibrium mixture of these five chemical species, provided nothing else is arbitrarily set. Thus it cannot simultaneously be required that the system be prepared from specified amounts of particular constituent species.

**Duhem's Theorem** Because the phase rule treats only the intensive state of a system, it applies to both closed and open systems. Duhem's theorem, on the other hand, is a rule relating to closed systems only: *For any closed system formed initially from given masses of prescribed chemical species, the equilibrium state is completely*

## 4-28 THERMODYNAMICS

**determined by any two properties of the system, provided only that the two properties are independently variable at the equilibrium state.** The meaning of completely determined is that both the intensive and extensive states of the system are fixed; not only are  $T$ ,  $P$ , and the phase compositions established, but so also are the masses of the phases.

### VAPOR/LIQUID EQUILIBRIUM

Vapor/liquid equilibrium (VLE) relationships (as well as other inter-phase equilibrium relationships) are needed in the solution of many engineering problems. The required data can be found by experiment, but measurements are seldom easy, even for binary systems, and they become ever more difficult as the number of species increases. This is the incentive for application of thermodynamics to the calculation of phase equilibrium relationships.

The general VLE problem treats a multicomponent system of  $N$  constituent species for which the independent variables are  $T$ ,  $P$ ,  $N - 1$  liquid-phase mole fractions, and  $N - 1$  vapor-phase mole fractions. (Note that  $\sum x_i = 1$  and  $\sum y_i = 1$ , where  $x_i$  and  $y_i$  represent liquid and vapor mole fractions, respectively.) Thus there are  $2N$  independent variables, and application of the phase rule shows that exactly  $N$  of these variables must be fixed to establish the intensive state of the system. This means that once  $N$  variables have been specified, the remaining  $N$  variables can be determined by simultaneous solution of the  $N$  equilibrium relations

$$f_i^l = f_i^v \quad i = 1, 2, \dots, N \quad (4-298)$$

where superscripts  $l$  and  $v$  denote the liquid and vapor phases, respectively.

In practice, either  $T$  or  $P$  and either the liquid-phase or vapor-phase composition are specified, thus fixing  $1 + (N - 1) = N$  independent variables. The remaining  $N$  variables are then subject to calculation, provided that sufficient information is available to allow determination of all necessary thermodynamic properties.

**Gamma/Phi Approach** For many VLE systems of interest, the pressure is low enough that a relatively simple equation of state, such as the two-term virial equation, is satisfactory for the vapor phase. Liquid-phase behavior, on the other hand, is described by an equation for the excess Gibbs energy, from which activity coefficients are derived. The fugacity of species  $i$  in the liquid phase is given by Eq. (4-221), and the vapor-phase fugacity is given by Eq. (4-204). These are here written as

$$\hat{f}_i^l = \gamma_i x_i f_i \quad \text{and} \quad \hat{f}_i^v = \hat{\phi}_i^v y_i P$$

$$\text{By Eq. (4-298),} \quad \gamma_i x_i f_i = \hat{\phi}_i^v y_i P \quad i = 1, 2, \dots, N \quad (4-299)$$

Identifying superscripts  $l$  and  $v$  are omitted here with the understanding that  $\gamma_i$  and  $f_i$  are liquid-phase properties, whereas  $\hat{\phi}_i$  is a vapor-phase property. Applications of Eq. (4-299) represent what is known as the *gamma/phi* approach to VLE calculations.

Evaluation of  $\hat{\phi}_i$  is usually by Eq. (4-243), based on the two-term virial equation of state. The activity coefficient  $\gamma_i$  is ultimately based on Eq. (4-251) applied to an expression for  $G^E/RT$ , as described in the section "Models for the Excess Gibbs Energy."

The fugacity  $f_i$  of pure compressed liquid  $i$  must be evaluated at the  $T$  and  $P$  of the equilibrium mixture. This is done in two steps. First, one calculates the fugacity coefficient of saturated vapor  $\hat{\phi}_i^v = \hat{\phi}_i^{\text{sat}}$  by an integrated form of Eq. (4-205), most commonly by Eq. (4-242) evaluated for pure species  $i$  at temperature  $T$  and the corresponding vapor pressure  $P = P_i^{\text{sat}}$ . Equation (4-298) written for pure species  $i$  becomes

$$f_i^v = f_i^l = f_i^{\text{sat}} \quad (4-300)$$

where  $f_i^{\text{sat}}$  indicates the value both for saturated liquid and for saturated vapor. Division by  $P_i^{\text{sat}}$  yields corresponding fugacity coefficients:

$$\frac{f_i^{\text{sat}}}{P_i^{\text{sat}}} = \frac{f_i^v}{P_i^{\text{sat}}} = \frac{f_i^l}{P_i^{\text{sat}}}$$

$$\text{or} \quad \hat{\phi}_i^v = \hat{\phi}_i^l = \hat{\phi}_i^{\text{sat}} \quad (4-301)$$

The second step is the evaluation of the change in fugacity of the liquid with a change in pressure to a value above or below  $P_i^{\text{sat}}$ . For this isothermal change of state from saturated liquid at  $P_i^{\text{sat}}$  to liquid at pressure  $P$ , Eq. (4-17) is integrated to give

$$G_i - G_i^{\text{sat}} = \int_{P_i^{\text{sat}}}^P V_i dP$$

Equation (4-199) is then written twice: for  $G_i$  and for  $G_i^{\text{sat}}$ . Subtraction provides another expression for  $G_i - G_i^{\text{sat}}$ :

$$G_i - G_i^{\text{sat}} = RT \ln \frac{f_i}{f_i^{\text{sat}}}$$

Equating the two expressions for  $G_i - G_i^{\text{sat}}$  yields

$$\ln \frac{f_i}{f_i^{\text{sat}}} = \frac{1}{RT} \int_{P_i^{\text{sat}}}^P V_i dP$$

Because  $V_i$ , the liquid-phase molar volume, is a very weak function of  $P$  at temperatures well below  $T_c$ , an excellent approximation is usually obtained when evaluation of the integral is based on the assumption that  $V_i$  is constant at the value for saturated liquid  $V_i^l$ :

$$\ln \frac{f_i}{f_i^{\text{sat}}} = \frac{V_i^l(P - P_i^{\text{sat}})}{RT}$$

Substituting  $f_i^{\text{sat}} = \hat{\phi}_i^{\text{sat}} P_i^{\text{sat}}$  and solving for  $f_i$  give

$$f_i = \hat{\phi}_i^{\text{sat}} P_i^{\text{sat}} \exp \frac{V_i^l(P - P_i^{\text{sat}})}{RT} \quad (4-302)$$

The exponential is known as the Poynting factor.

Equation (4-299) may now be written as

$$y_i P \Phi_i = x_i \gamma_i P_i^{\text{sat}} \quad i = 1, 2, \dots, N \quad (4-303)$$

where

$$\Phi_i = \frac{\hat{\phi}_i}{\hat{\phi}_i^{\text{sat}}} \exp \frac{-V_i^l(P - P_i^{\text{sat}})}{RT} \quad (4-304)$$

If evaluation of  $\hat{\phi}_i^{\text{sat}}$  and  $\hat{\phi}_i$  is by Eqs. (4-244) and (4-243), this reduces to

$$\Phi_i = \exp \frac{\overline{P} B_i - P_i^{\text{sat}} B_{ii} - V_i^l(P - P_i^{\text{sat}})}{RT} \quad (4-305)$$

where  $\overline{B}_i$  is given by Eq. (4-182).

The  $N$  equations represented by Eq. (4-303) in conjunction with Eq. (4-305) may be solved for  $N$  unknown phase equilibrium variables. For a multicomponent system the calculation is formidable, but well suited to computer solution.

When Eq. (4-303) is applied to VLE for which the vapor phase is an ideal gas and the liquid phase is an ideal solution, it reduces to a very simple expression. For ideal gases, fugacity coefficients  $\hat{\phi}_i$  and  $\hat{\phi}_i^{\text{sat}}$  are unity, and the right side of Eq. (4-304) reduces to the Poynting factor. For the systems of interest here, this factor is always very close to unity, and for practical purposes  $\Phi_i = 1$ . For ideal solutions, the activity coefficients  $\gamma_i$  are also unity, and Eq. (4-303) reduces to

$$y_i P = x_i P_i^{\text{sat}} \quad i = 1, 2, \dots, N \quad (4-306)$$

an equation which expresses *Raoult's law*. It is the simplest possible equation for VLE and as such fails to provide a realistic representation of real behavior for most systems. Nevertheless, it is useful as a standard of comparison.

**Modified Raoult's Law** Of the qualifications that lead to Raoult's law, the one least often reasonable is the supposition of solution ideality for the liquid phase. Real solution behavior is reflected by values of activity coefficients that differ from unity. When  $\gamma_i$  of Eq. (4-303) is retained in the equilibrium equation, the result is the *modified Raoult's law*:

$$y_i P = x_i \gamma_i P_i^{\text{sat}} \quad i = 1, 2, \dots, N \quad (4-307)$$

This equation is often adequate when applied to systems at low to moderate pressures and is therefore widely used. Bubble point and dew point calculations are only a bit more complex than the same calculations with Raoult's law.

Activity coefficients are functions of temperature and liquid-phase composition and are correlated through equations for the excess Gibbs energy. When an appropriate correlating equation for  $C^E$  is not available, suitable estimates of activity coefficients may often be obtained from a group contribution correlation. This is the "solution of groups" approach, wherein activity coefficients are found as sums of contributions from the structural groups that make up the molecules of a solution. The most widely applied such correlations are based on the UNIQUAC equation, and they have their origin in the UNIFAC method (UNIQUAC Functional-group Activity Coefficients), proposed by Fredenslund, Jones, and Prausnitz [*AIChE J.* **21**: 1086–1099 (1975)], and given detailed treatment by Fredenslund, Gmehling, and Rasmussen [*Vapor-Liquid Equilibrium Using UNIFAC*, Elsevier, Amsterdam (1977)].

Subsequent development has led to a variety of applications, including liquid/liquid equilibria [Magnussen, Rasmussen, and Fredenslund, *Ind. Eng. Chem. Process Des. Dev.* **20**: 331–339 (1981)], solid/liquid equilibria [Anderson and Prausnitz, *Ind. Eng. Chem. Fundam.* **17**: 269–273 (1978)], solvent activities in polymer solutions [Oishi and Prausnitz, *Ind. Eng. Chem. Process Des. Dev.* **17**: 333–339 (1978)], vapor pressures of pure species [Jensen, Fredenslund, and Rasmussen, *Ind. Eng. Chem. Fundam.* **20**: 239–246 (1981)], gas solubilities [Sander, Skjold-Jørgensen, and Rasmussen, *Fluid Phase Equilib.* **11**: 105–126 (1983)], and excess enthalpies [Dang and Tassios, *Ind. Eng. Chem. Process Des. Dev.* **25**: 22–31 (1986)].

The range of applicability of the original UNIFAC model has been greatly extended and its reliability enhanced. Its most recent revision and extension is treated by Wittig, Lohmann, and Gmehling [*Ind. Eng. Chem. Res.* **42**: 183–188 (2003)], wherein are cited earlier pertinent papers. Because it is based on temperature-independent parameters, its application is largely restricted to 0 to 150°C.

Two modified versions of the UNIFAC model, based on temperature-dependent parameters, have come into use. Not only do they provide a wide temperature range of applicability, but also they allow correlation of various kinds of property data, including phase equilibria, infinite dilution activity coefficients, and excess properties. The most recent revision and extension of the modified UNIFAC (Dortmund) model is provided by Gmehling et al. [*Ind. Eng. Chem. Res.* **41**: 1678–1688 (2002)]. An extended UNIFAC model called KT-UNIFAC is described in detail by Kang et al. [*Ind. Eng. Chem. Res.* **41**: 3260–3273 (2003)]. Both papers contain extensive literature citations.

The UNIFAC model has also been combined with the predictive Soave-Redlich-Kwong (PSRK) equation of state. The procedure is most completely described (with background literature citations) by Horstmann et al. [*Fluid Phase Equilibria* **227**: 157–164 (2005)].

Because  $\sum y_i = 1$ , Eq. (4-307) may be summed over all species to yield

$$P = \sum_i x_i \gamma_i P_i^{\text{sat}} \quad (4-308)$$

Alternatively, Eq. (4-307) may be solved for  $x_i$ , in which case summing over all species yields

$$P = \frac{1}{\sum_i y_i / \gamma_i P_i^{\text{sat}}} \quad (4-309)$$

**Example 3: Dew and Bubble Point Calculations** As indicated by Example 2a, a binary system in vapor/liquid equilibrium has 2 degrees of freedom. Thus of the four phase rule variables  $T$ ,  $P$ ,  $x_1$ , and  $y_1$ , two must be fixed to allow calculation of the other two, regardless of the formulation of the equilibrium equations. Modified Raoult's law [Eq. (4-307)] may therefore be applied to the calculation of any pair of phase rule variables, given the other two.

The necessary vapor pressures and activity coefficients are supplied by data correlations. For the system acetone(1)/*n*-hexane(2), vapor pressures are given by Eq. (4-142), the Antoine equation:

$$\ln P_i^{\text{sat}}/\text{kPa} = A_i - \frac{B_i}{T/\text{K} + C_i} \quad i = 1, 2 \quad (A)$$

with parameters

| $i$ | $A_i$   | $B_i$   | $C_i$   |
|-----|---------|---------|---------|
| 1   | 14.3145 | 2756.22 | -45.090 |
| 2   | 13.8193 | 2696.04 | -48.833 |

Activity coefficients are given by Eq. (4-274), the Wilson equation:

$$\ln \gamma_1 = -\ln(x_1 + x_2 \Lambda_{12}) + x_2 \lambda \quad (B)$$

$$\ln \gamma_2 = -\ln(x_2 + x_1 \Lambda_{21}) - x_1 \lambda \quad (C)$$

where

$$\lambda = \frac{\Lambda_{12}}{x_1 + x_2 \Lambda_{12}} - \frac{\Lambda_{21}}{x_2 + x_1 \Lambda_{21}}$$

$$\text{By Eq. (4-279)} \quad \Lambda_{ij} = \frac{V_j}{V_i} \exp \frac{-a_{ij}}{RT} \quad i \neq j$$

with parameters [Gmehling et al., *Vapor-Liquid Data Collection*, Chemistry Data Series, vol. 1, part 3, DECHEMA, Frankfurt/Main (1983)]

| $a_{12}$<br>cal mol <sup>-1</sup> | $a_{21}$<br>cal mol <sup>-1</sup> | $V_1$<br>cm <sup>3</sup> mol <sup>-1</sup> | $V_2$<br>cm <sup>3</sup> mol <sup>-1</sup> |
|-----------------------------------|-----------------------------------|--|--|
| 985.05                            | 453.57                            | 74.05                                      | 131.61                                     |

When  $T$  and  $x_1$  are given, the calculation is direct, with final values for vapor pressures and activity coefficients given immediately by Eqs. (A), (B), and (C). In all other cases either  $T$  or  $x_1$  or both are initially unknown, and calculations require trial or iteration.

*a. BUBL P* calculation: Find  $y_1$  and  $P$ , given  $x_1$  and  $T$ . Calculation here is direct. For  $x_1 = 0.40$  and  $T = 325.15$  K (52°C), Eqs. (A), (B), and (C) yield the values listed in the table on the following page. Equations (4-308) and (4-307) then become

$$P = x_1 \gamma_1 P_1^{\text{sat}} + x_2 \gamma_2 P_2^{\text{sat}} = (0.40)(1.8053)(87.616) + (0.60)(1.2569)(58.105) = 108.134 \text{ kPa}$$

$$y_1 = \frac{x_1 \gamma_1 P_1^{\text{sat}}}{P} = \frac{(0.40)(1.8053)(87.616)}{108.134} = 0.5851$$

*b. DEW P* calculation: Find  $x_1$  and  $P$ , given  $y_1$  and  $T$ . With  $x_1$  an unknown, the activity coefficients cannot be immediately calculated. However, an iteration scheme based on Eqs. (4-309) and (4-307) is readily devised, and is part of any solve routine of a software package. Starting values result from setting each  $\gamma_i = 1$ . For  $y_1 = 0.4$  and  $T = 325.15$  K (52°C), results are listed in the accompanying table.

*c. BUBL T* calculation: Find  $y_1$  and  $T$ , given  $x_1$  and  $P$ . With  $T$  unknown, neither the vapor pressures nor the activity coefficients can be initially calculated. An iteration scheme or a solve routine with starting values for the unknowns is required. Results for  $x_1 = 0.32$  and  $P = 80$  kPa are listed in the accompanying table.

*d. DEW T* calculation: Find  $x_1$  and  $T$ , given  $y_1$  and  $P$ . Again, an iteration scheme or a solve routine with starting values for the unknowns is required. For  $y_1 = 0.60$  and  $P = 101.33$  kPa, results are listed in the accompanying table.

*e. Azeotrope* calculations: As noted in Example 1a, only a single degree of freedom exists for this special case. The most sensitive quantity for identifying the azeotropic state is the *relative volatility*, defined as

$$\alpha_{12} = \frac{y_1/x_1}{y_2/x_2}$$

Because  $y_i = x_i$  for the azeotropic state,  $\alpha_{12} = 1$ . Substitution for the two ratios by Eq. (4-307) provides an equation for calculation of  $\alpha_{12}$  from the thermodynamic functions:

$$\alpha_{12} = \frac{\gamma_1 P_1^{\text{sat}}}{\gamma_2 P_2^{\text{sat}}}$$

Because  $\alpha_{12}$  is a monotonic function of  $x_1$ , the test of whether an azeotrope exists at a given  $T$  or  $P$  is provided by values of  $\alpha_{12}$  in the limits of  $x_1 = 0$  and  $x_1 = 1$ . If *both* values are either  $> 1$  or  $< 1$ , no azeotrope exists. But if one value is  $< 1$  and the other  $> 1$ , an azeotrope necessarily exists at the given  $T$  or  $P$ . Given  $T$ , the azeotropic composition and pressure is found by seeking the value of  $P$  that makes  $x_1 = y_1$  or that makes  $\alpha_{12} = 1$ . Similarly, given  $P$ , one finds the azeotropic composition and temperature. Shown in the accompanying table are calculated azeotropic states for a temperature of 46°C and for a pressure of 101.33 kPa. At 46°C, the limiting values of  $\alpha_{12}$  are 8.289 at  $x_1 = 0$  and 0.223 at  $x_1 = 1$ .

**Data Reduction** Correlations for  $G^E$  and the activity coefficients are based on VLE data taken at low to moderate pressures. Group-contribution methods, such as UNIFAC, depend for validity on parameters evaluated from a large base of such data. The process of finding a suitable analytic relation for  $g$  ( $\equiv G^E/RT$ ) as a function of its independent variables  $T$  and  $x_1$ , thus producing a correlation of VLE data, is known as data reduction. Although  $g$  is in principle also a function of  $P$ , the dependence is so weak as to be universally and properly neglected. Given here is a brief description of the treatment of data taken for binary systems under *isothermal* conditions. A more comprehensive development is given by Van Ness [J. Chem. Thermodyn. 27: 113–134 (1995); Pure & Appl. Chem. 67: 859–872 (1995)].

Presumed in all that follows is the existence of an equation inherently capable of correlating values of  $G^E$  for the liquid phase as a function of  $x_1$ :

$$g \equiv G^E/RT = \mathcal{G}(x_1; \alpha, \beta, \dots) \quad (4-310)$$

where  $\alpha, \beta, \dots$ , represent adjustable parameters.

The measured variables of binary VLE are  $x_1, y_1, T$ , and  $P$ . Experimental values of the activity coefficient of species  $i$  in the liquid are related to these variables by Eq. (4-303), written as

$$\gamma_i^\circ = \frac{y_i P^\circ}{x_i P^{\text{sat}}} \Phi_i \quad i = 1, 2 \quad (4-311)$$

where  $\Phi_i$  is given by Eq. (4-305) and the asterisks denote experimental values. A simple summability relation analogous to Eq. (4-252) defines an experimental value of  $g^\circ$ :

$$g^\circ \equiv x_1 \ln \gamma_1^\circ + x_2 \ln \gamma_2^\circ \quad (4-312)$$

Moreover, Eq. (4-263), the Gibbs-Duhem equation, may be written for experimental values in a binary system at constant  $T$  and  $P$  as

$$x_1 \frac{d \ln \gamma_1^\circ}{dx_1} + x_2 \frac{d \ln \gamma_2^\circ}{dx_1} = 0 \quad (4-313)$$

Because experimental measurements are subject to systematic error, sets of values of  $\ln \gamma_1^\circ$  and  $\ln \gamma_2^\circ$  may not satisfy, i.e., may not be *consistent* with, the Gibbs-Duhem equation. Thus Eq. (4-313) applied to sets of experimental values becomes a test of the thermodynamic consistency of the data, rather than a valid general relationship.

Values of  $g$  provided by the equation used to correlate the data, as represented by Eq. (4-310), are called *derived* values, and produce derived values of the activity coefficients by Eqs. (4-180) with  $M \equiv g$ :

$$\ln \gamma_1 = g + x_2 \frac{dg}{dx_1} \quad (4-314a)$$

$$\ln \gamma_2 = g - x_1 \frac{dg}{dx_1} \quad (4-314b)$$

These two equations combine to yield

$$\frac{dg}{dx_1} = \ln \frac{\gamma_1}{\gamma_2} \quad (4-315)$$

This equation is valid for *derived* property values. The corresponding *experimental* values are given by differentiation of Eq. (4-312):

$$\frac{dg^\circ}{dx_1} = x_1 \frac{d \ln \gamma_1^\circ}{dx_1} + \ln \gamma_1^\circ + x_2 \frac{d \ln \gamma_2^\circ}{dx_1} - \ln \gamma_2^\circ$$

$$\text{or} \quad \frac{dg^\circ}{dx_1} = \ln \frac{\gamma_1^\circ}{\gamma_2^\circ} + x_1 \frac{d \ln \gamma_1^\circ}{dx_1} + x_2 \frac{d \ln \gamma_2^\circ}{dx_1} \quad (4-316)$$

Subtraction of Eq. (4-316) from Eq. (4-315) gives

$$\frac{dg}{dx_1} - \frac{dg^\circ}{dx_1} = \ln \frac{\gamma_1}{\gamma_2} - \ln \frac{\gamma_1^\circ}{\gamma_2^\circ} - \left( x_1 \frac{d \ln \gamma_1^\circ}{dx_1} + x_2 \frac{d \ln \gamma_2^\circ}{dx_1} \right)$$

The differences between like terms represent *residuals* between derived and experimental values. Defining these residuals as

$$\delta g \equiv g - g^\circ \quad \text{and} \quad \delta \ln \frac{\gamma_i}{\gamma_j} \equiv \ln \frac{\gamma_i}{\gamma_j} - \ln \frac{\gamma_i^\circ}{\gamma_j^\circ}$$

puts this equation into the form

$$\frac{d \delta g}{dx_1} = \delta \ln \frac{\gamma_1}{\gamma_2} - \left( x_1 \frac{d \ln \gamma_1^\circ}{dx_1} + x_2 \frac{d \ln \gamma_2^\circ}{dx_1} \right)$$

If a data set is reduced so as to yield parameters— $\alpha, \beta$ , etc.—that make the  $\delta g$  residuals scatter about zero, then the derivative on the left is effectively zero, and the preceding equation becomes

$$\delta \ln \frac{\gamma_1}{\gamma_2} = x_1 \frac{d \ln \gamma_1^\circ}{dx_1} + x_2 \frac{d \ln \gamma_2^\circ}{dx_1} \quad (4-317)$$

The right side of this equation is the quantity required by Eq. (4-313), the Gibbs-Duhem equation, to be zero for consistent data. The residual on the left is therefore a direct measure of deviations from the Gibbs-Duhem equation. The extent to which values of this residual fail to scatter about zero measures the departure of the data from consistency with respect to this equation.

The data reduction procedure just described provides parameters in the correlating equation for  $g$  that make the  $\delta g$  residuals scatter about zero. This is usually accomplished by finding the parameters that minimize the sum of squares of the residuals. Once these parameters are found, they can be used for the calculation of derived values of both the pressure  $P$  and the vapor composition  $y_1$ . Equation (4-303) is solved for  $y_1 P$  and written for species 1 and for species 2. Adding the two equations gives

$$P = \frac{x_1 \gamma_1 P_1^{\text{sat}}}{\Phi_1} + \frac{x_2 \gamma_2 P_2^{\text{sat}}}{\Phi_2} \quad (4-318)$$

$$\text{whence by Eq. (4-303),} \quad y_1 = \frac{x_1 \gamma_1 P_1^{\text{sat}}}{\Phi_1 P} \quad (4-319)$$

These equations allow calculation of the *primary* residuals:

$$\delta P \equiv P - P^\circ \quad \text{and} \quad \delta y_1 \equiv y_1 - y_1^\circ$$

If the experimental values  $P^\circ$  and  $y_1^\circ$  are closely reproduced by the correlating equation for  $g$ , then these residuals, evaluated at the experimental values of  $x_1$ , scatter about zero. This is the result obtained when the data approach thermodynamic consistency. When they do not, these residuals fail to scatter about zero and the correlation for  $g$  does not properly reproduce the experimental values  $P^\circ$  and  $y_1^\circ$ .

Such a correlation is unnecessarily divergent. An alternative is to base data reduction on just the  $P$ - $x_1$  data subset; this is possible because the full  $P$ - $x_1$ - $y_1$  data set includes redundant information. Assuming that the correlating equation is appropriate to the data, one merely searches for values of the parameters  $\alpha, \beta$ , etc., that yield pressures by Eq. (4-318) that are as close as possible to the measured values. The usual procedure is to minimize the sum of squares of the residuals  $\delta P$ . Known as *Barker's method* [Austral. J. Chem. 6: 207–210 (1953)], it provides the best possible fit of the experimental pressures. When experimental  $y_1^\circ$  values are not consistent with the  $P$ - $x_1$  data, Barker's method cannot lead to calculated  $y_1$  values that closely match the experimental  $y_1^\circ$  values. With experimental error usually concentrated in the  $y_1^\circ$  values, the calculated  $y_1$  values are likely to be more nearly correct. Because Barker's method requires only the  $P$ - $x_1$  data subset, the measurement of  $y_1^\circ$  values is not usually worth the extra effort, and the correlating parameters  $\alpha, \beta$ , etc., are usually best determined without them. Hence, many  $P$ - $x_1$  data subsets appear in the literature; they are of course not subject to a test for consistency by the Gibbs-Duhem equation.

**FIG. 4-7** Plot of solute fugacity  $\hat{f}_1$  versus solute mole fraction. [Smith, Van Ness, and Abbott, *Introduction to Chemical Engineering Thermodynamics*, 7th ed., p. 555, McGraw-Hill, New York (2005).]

The world's store of VLE data has been compiled by Gmehling et al. [*Vapor-Liquid Equilibrium Data Collection*, Chemistry Data Series, vol. 1, parts 1–8, DECHEMA, Frankfurt am Main (1979–1990)].

**Solute/Solvent Systems** The gamma/phi approach to VLE calculations presumes knowledge of the vapor pressure of each species at the temperature of interest. For certain binary systems species 1, designated the solute, is either unstable at the system temperature or is *supercritical* ( $T > T_c$ ). Its vapor pressure cannot be measured, and its fugacity as a pure liquid at the system temperature  $f_1$  cannot be calculated by Eq. (4-302).

Equations (4-303) and (4-304) are applicable to species 2, designated the solvent, but not to the solute, for which an alternative approach is required. Figure 4-7 shows a typical plot of the liquid-phase fugacity of the solute  $\hat{f}_1$  versus its mole fraction  $x_1$  at constant temperature. Since the curve representing  $\hat{f}_1$  does not extend all the way to  $x_1 = 1$ , the location of  $f_1$ , the liquid-phase fugacity of pure species 1, is not established. The tangent line at the origin, representing *Henry's law*, provides alternative information. The slope of the tangent line is *Henry's constant*, defined as

$$k_1 \equiv \lim_{x_1 \rightarrow 0} \frac{\hat{f}_1}{x_1} \quad (4-320)$$

This is the definition of  $k_1$  for temperature  $T$  and for a pressure equal to the vapor pressure of the pure solvent  $P_2^{\text{sat}}$ .

The activity coefficient of the solute at infinite dilution is

$$\lim_{x_1 \rightarrow 0} \gamma_1 = \lim_{x_1 \rightarrow 0} \frac{\hat{f}_1}{x_1 f_1} = \frac{1}{f_1} \lim_{x_1 \rightarrow 0} \frac{\hat{f}_1}{x_1}$$

In view of Eq. (4-320), this becomes  $\gamma_1^\infty = k_1/f_1$ , or

$$f_1 = \frac{k_1}{\gamma_1^\infty} \quad (4-321)$$

where  $\gamma_1^\infty$  represents the infinite dilution value of the activity coefficient of the solute. Because both  $k_1$  and  $\gamma_1^\infty$  are evaluated at  $P_2^{\text{sat}}$ , this pressure also applies to  $f_1$ . However, the effect of  $P$  on a liquid-phase fugacity, given by a Poynting factor, is very small and for practical purposes may usually be neglected. The activity coefficient of the solute then becomes

$$\gamma_1 \equiv \frac{\hat{f}_1}{x_1 f_1} = \frac{y_1 P \hat{\phi}_1}{x_1 f_1} = \frac{y_1 P \hat{\phi}_1 \gamma_1^\infty}{x_1 k_1}$$

For the solute, this equation takes the place of Eqs. (4-303) and (4-304). Solution for  $y_1$  gives

$$y_1 = \frac{x_1 (\gamma_1 / \gamma_1^\infty) k_1}{\hat{\phi}_1 P} \quad (4-322)$$

For the solvent, species 2, the analog of Eq. (4-319) is

$$y_2 = \frac{x_2 \gamma_2 P_2^{\text{sat}}}{\hat{\Phi}_2 P} \quad (4-323)$$

$$\text{Because } y_1 + y_2 = 1, \quad P = \frac{x_1 (\gamma_1 / \gamma_1^\infty) k_1}{\hat{\phi}_1} + \frac{x_2 \gamma_2 P_2^{\text{sat}}}{\hat{\Phi}_2} \quad (4-324)$$

The same correlation that provides for the evaluation of  $\gamma_1$  also allows evaluation of  $\gamma_1^\infty$ .

There remains the problem of finding Henry's constant from the available VLE data.

For equilibrium  $\hat{f}_1 \equiv \hat{f}_1^l = \hat{f}_1^v = y_1 P \hat{\phi}_1$

$$\text{Division by } x_1 \text{ gives} \quad \frac{\hat{f}_1}{x_1} = P \hat{\phi}_1 \frac{y_1}{x_1}$$

Henry's constant is defined as the limit as  $x_1 \rightarrow 0$  of the ratio on the left; therefore

$$k_1 = P_2^{\text{sat}} \hat{\phi}_1^\infty \lim_{x_1 \rightarrow 0} \frac{y_1}{x_1}$$

The limiting value of  $y_1/x_1$  can be found by plotting  $y_1/x_1$  versus  $x_1$  and extrapolating to zero.

**K Values, VLE, and Flash Calculations** A measure of the distribution of a chemical species between liquid and vapor phases is the  $K$  value, defined as the equilibrium ratio:

$$K_i \equiv \frac{y_i}{x_i} \quad (4-325)$$

It has no thermodynamic content, but may make for computational convenience through elimination of one set of mole fractions in favor of the other. It does characterize "lightness" of a constituent species. A "light" species, with  $K > 1$ , tends to concentrate in the vapor phase whereas a "heavy" species, with  $K < 1$ , tends to concentrate in the liquid phase.

The rigorous evaluation of a  $K$  value follows from Eq. (4-299):

$$K_i \equiv \frac{y_i}{x_i} = \frac{\gamma_i f_i}{\hat{\phi}_i P} \quad (4-326)$$

When Raoult's law applies, Eq. (4-326) reduces to  $K_i = P_i^{\text{sat}}/P$ . For modified Raoult's law,  $K_i = \gamma_i P_i^{\text{sat}}/P$ . With  $K_i = y_i/x_i$ , these are alternative expressions of Raoult's law and modified Raoult's law. Were Raoult's valid,  $K$  values could be correlated as functions of just  $T$  and  $P$ . However, Eq. (4-326) shows that they are in general functions of  $T$ ,  $P$ ,  $\{x_i\}$ , and  $\{y_i\}$ , making convenient and accurate correlation impossible. Those correlations that do exist are approximate and severely limited in application. The nomographs for  $K$  values of light hydrocarbons as functions of  $T$  and  $P$ , prepared by DePriester [*Chem. Eng. Progr. Symp. Ser. No. 7*, 49: 1–43 (1953)], do allow for an *average* effect of composition, but their essential basis is Raoult's law.

The defining equation for  $K$  can be rearranged as  $y_i = K_i x_i$ . The sum  $\sum_i y_i = 1$  then yields

$$\sum_i K_i x_i = 1 \quad (4-327)$$

With the alternative rearrangement  $x_i = y_i/K_i$ , the sum  $\sum_i x_i = 1$  yields

$$\sum_i \frac{y_i}{K_i} = 1 \quad (4-328)$$

Thus for bubble point calculations, where the  $x_i$  are known, the problem is to find the set of  $K$  values that satisfies Eq. (4-327), whereas for dew point calculations, where the  $y_i$  are known, the problem is to find the set of  $K$  values that satisfies Eq. (4-328).

The *flash calculation* is a very common application of VLE. Considered here is the  $P, T$  flash, in which are calculated the quantities and compositions of the vapor and liquid phases in equilibrium at known  $T, P$ , and *overall* composition. This problem is determinate on the basis of Duhem's theorem: *For any closed system formed initially from*

## 4-32 THERMODYNAMICS

given masses of prescribed chemical species, the equilibrium state is completely determined when any two independent variables are fixed. The independent variables are here  $T$  and  $P$ , and systems are formed from given masses of nonreacting chemical species.

For 1 mol of a system with overall composition represented by the set of mole fractions  $\{z_i\}$ , let  $\mathcal{L}$  represent the molar fraction of the system that is liquid (mole fractions  $\{x_i\}$ ) and let  $\mathcal{V}$  represent the molar fraction that is vapor (mole fractions  $\{y_i\}$ ). The material balance equations are

$$\mathcal{L} + \mathcal{V} = 1 \quad \text{and} \quad z_i = x_i \mathcal{L} + y_i \mathcal{V} \quad i = 1, 2, \dots, N$$

Combining these equations to eliminate  $\mathcal{L}$  gives

$$z_i = x_i(1 - \mathcal{V}) + y_i \mathcal{V} \quad i = 1, 2, \dots, N \quad (4-329)$$

Substitute  $x_i = y_i/K_i$  and solve for  $y_i$ :

$$y_i = \frac{z_i K_i}{1 + \mathcal{V}(K_i - 1)} \quad i = 1, 2, \dots, N$$

Because  $\sum y_i = 1$ , this equation, summed over all species, yields

$$\sum_i \frac{z_i K_i}{1 + \mathcal{V}(K_i - 1)} = 1 \quad (4-330)$$

The initial step in solving a  $P, T$  flash problem is to find the value of  $\mathcal{V}$  which satisfies this equation. Note that  $\mathcal{V} = 1$  is always a *trivial* solution.

**Example 4: Flash Calculation** The system of Example 3 has the overall composition  $z_1 = 0.4000$  at  $T = 325.15$  K and  $P = 101.33$  kPa. Determine  $\mathcal{V}$ ,  $x_1$ , and  $y_1$ .

The *BUBL P* and *DEW P* calculations at  $T = 325.15$  K of Example 3a and 3b show that for  $x_1 = z_1$ ,  $P_{\text{bubl}} = 108.134$  kPa, and for  $y_1 = z_1$ ,  $P_{\text{dew}} = 87.939$  kPa. Because  $P$  here lies between these values, the system is in two-phase equilibrium, and a flash calculation is appropriate.

The modified Raoult's law  $K$  values are given by

$$K_1 = \frac{(\gamma_1)(P_1^{\text{sat}})}{P} \quad \text{and} \quad K_2 = \frac{(\gamma_2)(P_2^{\text{sat}})}{P}$$

Equation (4-329) may be solved for  $\mathcal{V}$ :  $\mathcal{V} = \frac{z_1 - x_1}{y_1 - x_1}$

Equation (4-330) here becomes

$$\frac{(z_1)(K_1)}{1 + \mathcal{V}(K_1 - 1)} + \frac{(z_2)(K_2)}{1 + \mathcal{V}(K_2 - 1)} = 1$$

A trial calculation illustrates the nature of the solution. Vapor pressures are taken from Example 3a or 3b; a trial value of  $x_1$  then allows calculation of  $\gamma_1$  and  $\gamma_2$  by Eqs. (B) and (C) of Example 3. The values of  $K_1$ ,  $K_2$ , and  $\mathcal{V}$  that result are substituted into the summation equation. In the unlikely event that the sum is indeed unity, the chosen value of  $x_1$  is correct. If not, then successive trials easily lead to this value. Note that the trivial solution giving  $\mathcal{V} = 1$  must be avoided. More elegant solution procedures can of course be employed. The answers are

$$x_1 = 0.2373 \quad y_1 = 0.5190 \quad \mathcal{V} = 0.5775$$

with  $\gamma_1 = 2.5297 \quad \gamma_2 = 1.0997 \quad K_1 = 2.1873 \quad K_2 = 0.6306$

**Equation-of-State Approach** Although the gamma/phi approach to VLE is in principle generally applicable to systems comprised of subcritical species, in practice it has found use primarily where pressures are no more than a few bars. Moreover, it is most satisfactory for correlation of constant-temperature data. A temperature dependence for the parameters in expressions for  $G^E$  is included only for the local composition equations, and it is at best approximate.

A generally applicable alternative to the gamma/phi approach results when both the liquid and vapor phases are described by the same equation of state. The defining equation for the fugacity coefficient, Eq. (4-204), may be applied to each phase:

$$\text{Liquid: } \hat{f}_i^l = \hat{\phi}_i^l x_i P \quad \text{Vapor: } \hat{f}_i^v = \hat{\phi}_i^v y_i P$$

By Eq. (4-298),  $x_i \hat{\phi}_i^l = y_i \hat{\phi}_i^v \quad i = 1, 2, \dots, N \quad (4-331)$

This introduces compositions  $x_i$  and  $y_i$  into the equilibrium equations, but neither is explicit, because the  $\hat{\phi}_i$  are functions, not only of  $T$  and

**FIG. 4-8** A subcritical isotherm on a  $PV$  diagram for a pure fluid. [Smith, Van Ness, and Abbott, Introduction to Chemical Engineering Thermodynamics, 7th ed., p. 557, McGraw-Hill, New York (2005).]

$P$ , but of composition. Thus, Eq. (4-331) represents  $N$  complex relationships connecting  $T$ ,  $P$ ,  $\{x_i\}$ , and  $\{y_i\}$ .

Two widely used cubic equations of state appropriate for VLE calculations, both special cases of Eq. (4-100) [with Eqs. (4-101) and (4-102)], are the Soave-Redlich-Kwong (SRK) equation and the Peng-Robinson (PR) equation. The present treatment is applicable to both. The pure numbers  $\epsilon$ ,  $\sigma$ ,  $\Psi$ , and  $\Omega$  and expressions for  $\alpha(T_i)$  specific to these equations are listed in Table 4-2. The associated expression for  $\phi_i$  is given by Eq. (4-246).

The simplest application of equations of state in vapor/liquid equilibrium is to the calculation of vapor pressures  $P_i^{\text{sat}}$  of pure liquids. Vapor pressures can of course be measured, but values are also implicit in cubic equations of state.

A subcritical  $PV$  isotherm, generated by a cubic equation of state, is shown in Fig. 4-8. Three segments are evident. The very steep one on the left ( $rs$ ) is characteristic of liquids. Note that as  $P \rightarrow \infty, V \rightarrow b$ , where  $b$  is a constant in the cubic equation. The gently sloping segment on the right ( $tu$ ) is characteristic of vapors; here  $\dot{P} \rightarrow 0$  as  $V \rightarrow \infty$ . The middle segment ( $st$ ), with both a minimum (note  $P < 0$ ) and a maximum, provides a transition from liquid to vapor, but has no physical meaning. The actual transition occurs along a horizontal line, such as connects points  $M$  and  $W$ .

For pure species  $i$ , Eq. (4-331) reduces to  $\phi_i^v = \phi_i^l$ , which may be written as

$$\ln \phi_i^v = \ln \phi_i^l \quad (4-332)$$

For given  $T$ , line  $MW$  lies at the vapor pressure  $P_i^{\text{sat}}$  if and only if the fugacity coefficients for points  $M$  and  $W$  satisfy Eq. (4-332). These points then represent *saturated* liquid and vapor phases in equilibrium at temperature  $T$ .

The fugacity coefficients in Eq. (4-332) are given by Eq. (4-245):

$$\ln \phi_i^p = Z_i^p - 1 - \ln(Z_i^p - \beta_i) - q_i I_i^p \quad p = l, v \quad (4-333)$$

Expressions for  $Z_i^v$  and  $Z_i^l$  come from Eqs. (4-104):

$$Z_i^v = 1 + \beta_i - q_i \beta_i \frac{Z_i^v - \beta_i}{(Z_i^v + \epsilon \beta_i)(Z_i^v + \sigma \beta_i)} \quad (4-334)$$

$$Z_i^l = \beta_i + (Z_i^l + \epsilon \beta_i)(Z_i^l + \sigma \beta_i) \left( \frac{1 + \beta_i - Z_i^l}{q_i \beta_i} \right) \quad (4-335)$$

and  $I_i^p$  comes from Eq. (4-112):

$$I_i^p = \frac{1}{\sigma - \epsilon} \ln \frac{Z_i^p + \sigma \beta_i}{Z_i^p + \epsilon \beta_i} \quad p = l, v \quad (4-336)$$

The equation-of-state parameters are independent of phase. As defined by Eq. (4-105),  $\beta_i$  is a function of  $P$  and here becomes

$$\beta_i \equiv \frac{b_i P_i^{\text{sat}}}{RT} \quad (4-337)$$

The remaining equation-of-state parameters, given by Eqs. (4-101), (4-102), and (4-106), are functions of  $T$  only and are written here as

$$a_i(T) = \psi \frac{\alpha(T_r) R^2 T_c^2}{P_c} \quad (4-338)$$

$$b_i = \Omega \frac{RT_c}{P_c} \quad (4-339)$$

$$q_i \equiv \frac{a_i(T)}{b_i RT} \quad (4-340)$$

The eight equations (4-332) through (4-337) may be solved for the eight unknowns  $P_i^{\text{sat}}$ ,  $\beta_i$ ,  $Z_i^l$ ,  $Z_i^v$ ,  $I_i^l$ ,  $I_i^v$ ,  $\ln \phi_i^l$ , and  $\ln \phi_i^v$ .

Perhaps more useful is the reverse calculation whereby an equation-of-state parameter is evaluated from a known vapor pressure. Thus, Eqs. (4-332) and (4-333) may be combined and solved for  $q_i$ , yielding

$$q_i = \frac{Z_i^v - Z_i^l + \ln [(Z_i^l - \beta_i)/(Z_i^v - \beta_i)]}{I_i^v - I_i^l} \quad (4-341)$$

Expressions for  $Z_i^l$ ,  $Z_i^v$ ,  $I_i^l$ ,  $I_i^v$ , and  $\beta_i$  are given by Eqs. (4-334) through (4-337). Because  $Z_i^l$  and  $Z_i^v$  depend on  $q_i$ , an iterative procedure is indicated, with a starting value for  $q_i$  from a generalized correlation as given by Eqs. (4-338), (4-339), and (4-340).

For mixtures the presumption is that the equation of state has exactly the same form as when written for pure species. Equations (4-104) are therefore applicable, with parameters  $\beta$  and  $q$  given by Eqs. (4-105) and (4-106). Here, these parameters, and therefore  $b$  and  $a(T)$ , are *functions of composition*. Liquid and vapor mixtures in equilibrium in general have different compositions. The  $PV$  isotherms generated by an equation of state for these different compositions are represented in Fig. 4-9 by two similar lines: the solid line for the liquid-phase composition and the dashed line for the vapor-phase composition. They are displaced from each other because the equation-of-state parameters are different for the two compositions.

**FIG. 4-9** Two  $PV$  isotherms at the same  $T$  for mixtures. The solid line is for a liquid-phase composition; the dashed line is for a vapor-phase composition. Point  $B$  represents a bubble point with the liquid-phase composition; point  $D$  represents a dew point with the vapor-phase composition. When these points lie at the same  $P$  (as shown), they represent phases in equilibrium. [Smith, Van Ness, and Abbott, *Introduction to Chemical Engineering Thermodynamics*, 7th ed., p. 560, McGraw-Hill, New York (2005).]

Each line includes three *segments* as described for the isotherm of Fig. 4-8: the leftmost segment representing a liquid phase and the rightmost segment, a vapor phase, *both with the same composition*. Each left segment contains a bubble point (saturated liquid), and each right segment contains a dew point (saturated vapor). Because these points for a given line are for the same composition, they do not represent phases in equilibrium and do not lie at the same pressure. Shown in Fig. 4-9 is a bubble point  $B$  on the solid line and a dew point  $D$  on the dashed line. Because they lie at the same  $P$ , they represent phases in equilibrium, and the lines are characterized by the liquid and vapor compositions.

For a *BUBL P* calculation, the temperature and the liquid composition are known, and this fixes the location of the  $PV$  isotherm for the composition of the liquid phase (solid line). The problem then is to locate a second (dashed) line for a vapor composition such that the line contains a dew point  $D$  on its vapor segment that lies at the pressure of the bubble point  $B$  on the liquid segment of the solid line. This pressure is the phase equilibrium pressure, and the composition for the dashed line is that of the equilibrium vapor. This equilibrium condition is shown by Fig. 4-9.

In the absence of a theory to prescribe the composition dependence of parameters for cubic equations of state, empirical *mixing rules* are used to relate mixture parameters to pure-species parameters. The simplest realistic expressions are a linear mixing rule for parameter  $b$  and a quadratic mixing rule for parameter  $a$ , as shown by Eqs. (4-113) and (4-114). A common combining rule is given by Eq. (4-115). The general mole fraction variable  $x_i$  is used here because application is to both liquid and vapor mixtures. These equations, known as van der Waals prescriptions, provide for the evaluation of mixture parameters solely for parameters for the pure constituent species. They find application primarily for mixtures comprised of simple and chemically similar molecules.

Useful in the application of cubic equations of state to mixtures are *partial* equation-of-state parameters. For the parameters of the generic cubic, represented by Eqs. (4-104), (4-105), and (4-106), the definitions are

$$\bar{a}_i \equiv \left[ \frac{\partial(na)}{\partial n_i} \right]_{T,n_j} \quad (4-342)$$

$$\bar{b}_i \equiv \left[ \frac{\partial(nb)}{\partial n_i} \right]_{T,n_j} \quad (4-343)$$

$$\bar{q}_i \equiv \left[ \frac{\partial(nq)}{\partial n_i} \right]_{T,n_j} \quad (4-344)$$

These are general equations, valid regardless of the particular mixing or combining rules adopted for the composition dependence of mixture parameters.

Parameter  $q$  is defined in relation to parameters  $a$  and  $b$  by Eq. (4-106). Thus,

$$nq = \frac{n(na)}{RT(nb)}$$

$$\text{whence} \quad \bar{q}_i \equiv \left[ \frac{\partial(nq)}{\partial n_i} \right]_{T,n_j} = q \left( 1 + \frac{\bar{a}_i}{a} - \frac{\bar{b}_i}{b} \right) \quad (4-345)$$

Any two of the three partial parameters form an independent pair, and any one of them can be found from the other two. Because  $q$ ,  $a$ , and  $b$  are not linearly related,  $\bar{q}_i \neq \bar{a}_i/\bar{b}_i/RT$ .

Values of  $\hat{\phi}_i^l$  and  $\hat{\phi}_i^v$  as given by Eq. (4-246) are implicit in an equation of state and with Eq. (4-331) allow calculation of *mixture* VLE. Although more complex, the same basic principle applies as for pure-species VLE. With  $\hat{\phi}_i^l$  a function of  $T$ ,  $P$ , and  $\{x_i\}$ , and  $\hat{\phi}_i^v$  a function of  $T$ ,  $P$ , and  $\{y_i\}$ , Eq. (4-331) represents  $N$  relations among the  $2N$  variables:  $T$ ,  $P$ ,  $(N-1)$   $x$ 's, and  $(N-1)$   $y$ 's. Thus, specification of  $N$  of these variables, usually either  $T$  or  $P$  and either the liquid- or vapor-phase composition, allows solution for the remaining  $N$  variables by *BUBL P*, *DEW P*, *BUBL T*, and *DEW T* calculations.

Because of limitations inherent in empirical mixing and combining rules, such as those given by Eqs. (4-113) through (4-115), the equation-of-state approach has found primary application to systems exhibiting modest deviations from ideal solution behavior in the liquid phase, e.g., to systems containing hydrocarbons and cryogenic fluids. However, since 1990, extensive research has been devoted to developing mixing rules that incorporate the excess Gibbs energy or activity coefficient data available for many systems. The extensive literature on this subject is reviewed by Valderrama [*Ind. Eng. Chem. Res.* **42**: 1603–1618 (2003)] and by Twu, Sim, and Tassone [*Chem. Eng. Progress* **98**(11): 58–65 (Nov. 2002)].

The idea here is to exploit the connection between fugacity coefficients and activity coefficients provided by their definitions:

$$\gamma_i \equiv \frac{\hat{f}_i}{x_i f_i} = \frac{\hat{f}_i/x_i P}{f_i/P} = \frac{\hat{\phi}_i}{\phi_i}$$

Therefore,  $\ln \gamma_i = \ln \hat{\phi}_i - \ln \phi_i$  (4-346)

Because  $\gamma_i$  is a liquid-phase property, this equation is written for the liquid phase. Substituting for  $\ln \hat{\phi}_i$  and  $\ln \phi_i$  by Eqs. (4-245) and Eq. (4-246) gives

$$\ln \gamma_i = \frac{b_i}{b} (Z - 1) - Z_i + 1 - \ln \frac{Z - \beta}{Z_i - \beta_i} - \bar{q}_i I + q_i I_i$$

Symbols without subscripts are mixture properties. Solution for  $\bar{q}_i$  yields

$$\bar{q}_i = \frac{1}{I} \left[ 1 - Z_i + \frac{b_i}{b} (Z - 1) - \ln \frac{Z - \beta}{Z_i - \beta_i} + q_i I_i - \ln \gamma_i \right] \quad (4-347)$$

Because  $\bar{q}_i$  is a partial property, the summability equation provides an exact mixing rule:

$$q = \sum_i x_i \bar{q}_i \quad (4-348)$$

Application of this equation in the solution of VLE problems is illustrated by Smith, Van Ness, and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., pp. 569–572, McGraw-Hill, New York (2005)].

**Extrapolation of Data with Temperature** Liquid-phase excess-property data for binary systems at near-ambient temperatures appear in the literature. They provide for the extrapolation of  $G^E$  correlations with temperature. The key relations are Eq. (4-250), written as

$$d\left(\frac{G^E}{RT}\right) = -\frac{H^E}{RT^2} dT \quad \text{constant } P, x$$

and the excess-property analog of Eq. (4-26):

$$dH^E = C_P^E dT \quad \text{constant } P, x$$

Integration of the first equation from  $T_0$  to  $T$  gives

$$\frac{G^E}{RT} = \left(\frac{G^E}{RT}\right)_{T_0} - \int_{T_0}^T \frac{H^E}{RT^2} dT \quad (4-349)$$

Integration of the second equation from  $T_1$  to  $T$  yields

$$H^E = H_1^E + \int_{T_1}^T C_P^E dT \quad (4-350)$$

In addition,

$$dC_P^E = \left(\frac{\partial C_P^E}{\partial T}\right)_{P,x} dT$$

Integrate from  $T_2$  to  $T$ :

$$C_P^E = C_{P_2}^E + \int_{T_2}^T \left(\frac{\partial C_P^E}{\partial T}\right)_{P,x} dT$$

Combining this equation with Eqs. (4-349) and (4-350) leads to

$$\begin{aligned} \frac{G^E}{RT} = & \left(\frac{G^E}{RT}\right)_{T_0} - \left(\frac{H^E}{RT}\right)_{T_1} \left(\frac{T}{T_0} - 1\right) \frac{T_1}{T} \\ & - \frac{C_{P_2}^E}{R} \left[ \ln \frac{T}{T_0} - \left(\frac{T}{T_0} - 1\right) \frac{T_1}{T} \right] - I \end{aligned} \quad (4-351)$$

where

$$I \equiv \int_{T_0}^T \frac{1}{RT^2} \int_{T_1}^T \left(\frac{\partial C_P^E}{\partial T}\right)_{P,x} dT dT dT$$

This general equation employs excess Gibbs energy data at temperature  $T_0$ , excess enthalpy (heat-of-mixing) data at  $T_1$ , and excess heat capacity data at  $T_2$ . Integral  $I$  depends on the temperature dependence of  $C_P^E$ . Excess heat capacity data are uncommon, and the  $T$  dependence is rarely known. Assuming  $C_P^E$  independent of  $T$  makes the integral zero, and the closer  $T_0$  and  $T_1$  are to  $T$ , the less the influence of this assumption. When no information is available for  $C_P^E$  and excess enthalpy data are available at only a single temperature,  $C_P^E$  must be assumed zero. In this case only the first two terms on the right side of Eq. (4-351) are retained, and it more rapidly becomes imprecise as  $T$  increases.

For application of Eq. (4-351) to binary systems at *infinite dilution* of one of the constituent species, it is divided by the product  $x_1 x_2$ .

$$\begin{aligned} \frac{G^E}{x_1 x_2 RT} = & \left(\frac{G^E}{x_1 x_2 RT}\right)_{T_0} - \left(\frac{H^E}{x_1 x_2 RT}\right)_{T_1} \left(\frac{T}{T_0} - 1\right) \frac{T_1}{T} \\ & - \frac{C_{P_2}^E}{x_1 x_2 R} \left[ \ln \frac{T}{T_0} - \left(\frac{T}{T_0} - 1\right) \frac{T_1}{T} \right] \end{aligned}$$

The assumption here is that  $C_P^E$  is independent of  $T$ , making  $I = 0$ . As shown by Smith, Van Ness and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 7th ed., p. 437, McGraw-Hill, New York (2005)],

$$\left(\frac{G^E}{x_1 x_2 RT}\right)_{x_i=0} \equiv \ln \gamma_i^\infty$$

The preceding equation may therefore be written as

$$\begin{aligned} \ln \gamma_i^\infty = & (\ln \gamma_i^\infty)_{T_0} - \left(\frac{H^E}{x_1 x_2 RT}\right)_{T_1, x_i=0} \left(\frac{T}{T_0} - 1\right) \frac{T_1}{T} \\ & - \left(\frac{C_{P_2}^E}{x_1 x_2 R}\right)_{x_i=0} \left[ \ln \frac{T}{T_0} - \left(\frac{T}{T_0} - 1\right) \frac{T_1}{T} \right] \end{aligned} \quad (4-352)$$

**Example 5: VLE at Several Temperatures** For the methanol(1)/acetone(2) system at a base temperature of  $T_0 = 323.15$  K (50°C), both VLE data [Van Ness and Abbott, *Int. DATA Ser., Ser. A, Sel. Data Mixtures*, **1978**: 67 (1978)] and excess enthalpy data [Morris et al., *J. Chem. Eng. Data* **20**: 403–405 (1975)] are available. The VLE data are well correlated by the Margules equations. As noted in connection with Eq. (4-270), parameters  $A_{12}$  and  $A_{21}$  relate directly to infinite dilution values of the activity coefficients. Thus, we have from the VLE data at 323.15 K:

$$A_{12} = \ln \gamma_1^\infty = 0.6281 \quad \text{and} \quad A_{21} = \ln \gamma_2^\infty = 0.6557$$

These values allow calculation of equilibrium pressures through Eqs. (4-270) and (4-308) for comparison with the measured pressures of the data set. Values of  $P_i^{\text{sat}}$  required in Eq. (4-308) are the measured values reported with the data set. The root-mean-square (rms) value of the pressure differences is given in Table 4-7 as 0.08 kPa, thus confirming the suitability of the Margules equation for this system. Vapor-phase mole fractions were not reported; hence no value can be given for rms  $\delta y_1$ .

Experimental VLE data at 372.8 and 397.7 K are given by Wilsak et al. [*Fluid Phase Equilib.* **28**: 13–37 (1986)]. Values of  $\ln \gamma_i^\infty$  and hence of the Margules parameters for these higher temperatures are found from Eq. (4-352) with  $C_P^E = 0$ . The required excess enthalpy values at  $T_0$  are

$$\left(\frac{H^E}{x_1 x_2 RT}\right)_{T_0, x_i=0} = 1.3636 \quad \text{and} \quad \left(\frac{H^E}{x_1 x_2 RT}\right)_{T_0, x_2=0} = 1.0362$$

TABLE 4-7 VLE Results for Methanol(1)/Acetone(2)

| T, K   | $A_{12} = \ln \gamma_1^\infty$ | $A_{21} = \ln \gamma_2^\infty$ | RMS $\delta P/kPa$ | RMS % $\delta P$ | RMS $\delta y_1$ |
|--------|--------------------------------|--------------------------------|--------------------|------------------|------------------|
| 323.15 | 0.6281                         | 0.6557                         | 0.08               | 0.12             |                  |
| 372.8  | 0.4465<br>(0.4607)             | 0.5177<br>(0.5271)             | 0.85<br>(0.83)     | 0.22             | 0.004<br>(0.006) |
| 397.7  | 0.3725<br>(0.3764)             | 0.4615<br>(0.4640)             | 2.46<br>(1.39)     | 0.32             | 0.014<br>(0.013) |

Results of calculations with the Margules equations are displayed as the primary entries at each temperature in Table 4-7. The values in parentheses are from the gamma/phi approach as reported in the papers cited.

Results for the higher temperatures indicate the quality of predictions based only on vapor-pressure data for the pure species and on mixture data at 323.15 K. Extrapolations based on the same data to still higher temperatures can be expected to become progressively less accurate.

Only the Wilson, NRTL, and UNIQUAC equations are suited to the treatment of multicomponent systems. For such systems, the parameters are determined for pairs of species exactly as for a binary system.

### LIQUID/LIQUID AND VAPOR/LIQUID/LIQUID EQUILIBRIA

Equation (4-295) is the basis for both liquid/liquid equilibria (LLE) and vapor/liquid/liquid equilibria (VLLE). Thus for LLE with supercritical  $\alpha$  and  $\beta$  denoting the two phases, Eq. (4-295) is written as

$$\hat{f}_i^\alpha = \hat{f}_i^\beta \quad i = 1, 2, \dots, N \quad (4-353)$$

Eliminating fugacities in favor of activity coefficients gives

$$x_i^\alpha \gamma_i^\alpha = x_i^\beta \gamma_i^\beta \quad i = 1, 2, \dots, N \quad (4-354)$$

For most LLE applications, the effect of pressure on the  $\gamma_i$  can be ignored, and Eq. (4-354) then constitutes a set of  $N$  equations relating equilibrium compositions to one another and to temperature. For a given temperature, solution of these equations requires a single expression for the composition dependence of  $G^E$  suitable for both liquid phases. Not all expressions for  $G^E$  suffice, even in principle, because some cannot represent liquid/liquid phase splitting. The UNIQUAC equation is suitable, and therefore prediction is possible by UNIFAC models. A special table of parameters for LLE calculations is given by Magnussen et al. [*Ind. Eng. Chem. Process Des. Dev.* **20**: 331–339 (1981)].

A comprehensive treatment of LLE is given by Sorensen et al. [*Fluid Phase Equilib.* **2**: 297–309 (1979); **3**: 47–82 (1979); **4**: 151–163 (1980)]. Data for LLE are collected in a three-part set compiled by Sorensen and Arlt [*Liquid-Liquid Equilibrium Data Collection*, Chemistry Data Series, vol. 5, parts 1–3, DECHEMA, Frankfurt am Main (1979–1980)].

For vapor/liquid/liquid equilibria, Eq. (4-295) becomes

$$\hat{f}_i^\alpha = \hat{f}_i^\beta = \hat{f}_i^v \quad i = 1, 2, \dots, N \quad (4-355)$$

where  $\alpha$  and  $\beta$  designate the two liquid phases. With activity coefficients applied to the liquid phases and fugacity coefficients to the vapor phase, the  $2N$  equilibrium equations for subcritical VLLE are

$$\left. \begin{aligned} x_i^\alpha \gamma_i^\alpha \phi_i^\alpha &= y_i \hat{\phi}_i P \\ x_i^\beta \gamma_i^\beta \phi_i^\beta &= y_i \hat{\phi}_i P \end{aligned} \right\} \quad \text{all } i \quad (4-356)$$

As for LLE, an expression for  $C^E$  capable of representing liquid/liquid phase splitting is required; as for VLE, a vapor-phase equation of state for computing the  $\hat{\phi}_i$  is also needed.

### CHEMICAL REACTION STOICHIOMETRY

For a phase in which a chemical reaction occurs according to the equation

the  $|v_i|$  are stoichiometric coefficients and the  $A_i$  stand for chemical formulas. The  $v_i$  themselves are called stoichiometric numbers, and associated with them is a sign convention such that the value is positive for a product and negative for a reactant. More generally, for a system containing  $N$  chemical species, any or all of which can participate in  $r$  chemical reactions, the reactions are represented by the equations

$$0 = \sum_i v_{ij} A_i \quad j = \text{I, II, } \dots, r \quad (4-357)$$

where  $\text{sign}(v_{i,j}) = \begin{cases} - & \text{for a reactant species} \\ + & \text{for a product species} \end{cases}$

If species  $i$  does not participate in reaction  $j$ , then  $v_{ij} = 0$ .

The stoichiometric numbers provide relations among the changes in mole numbers of chemical species which occur as the result of chemical reaction. Thus, for reaction  $j$

$$\frac{\Delta n_{1,j}}{v_{1,j}} = \frac{\Delta n_{2,j}}{v_{2,j}} = \dots = \frac{\Delta n_{N,j}}{v_{N,j}} \quad (4-358)$$

All these terms are equal, and they can be equated to the change in a single quantity  $\epsilon_j$ , called the *reaction coordinate* for reaction  $j$ , thereby giving

$$\Delta n_{i,j} = v_{i,j} \Delta \epsilon_j \quad \begin{aligned} i &= 1, 2, \dots, N \\ j &= \text{I, II, } \dots, r \end{aligned} \quad (4-359)$$

Because the total change in mole number  $\Delta n_i$  is just the sum of the changes  $\Delta n_{i,j}$  resulting from the various reactions,

$$\Delta n_i = \sum_j \Delta n_{i,j} = \sum_j v_{i,j} \Delta \epsilon_j \quad i = 1, 2, \dots, N \quad (4-360)$$

If the initial number of moles of species  $i$  is  $n_{i0}$  and if the convention is adopted that  $\epsilon_j = 0$  for each reaction in this initial state, then

$$n_i = n_{i0} + \sum_j v_{i,j} \epsilon_j \quad i = 1, 2, \dots, N \quad (4-361)$$

Equation (4-361) is the basic expression of material balance for a closed system in which  $r$  chemical reactions occur. It shows for a reacting system that at most  $r$  mole-number-related quantities  $\epsilon_j$  are capable of independent variation. It is not an equilibrium relation, but merely an accounting scheme, valid for tracking the progress of the reactions to arbitrary levels of conversion. The reaction coordinate has units of moles. A change in  $\epsilon_j$  of 1 mol signifies a *mole of reaction*, meaning that reaction  $j$  has proceeded to such an extent that the change in mole number of each reactant and product is equal to its stoichiometric number.

### CHEMICAL REACTION EQUILIBRIA

The general criterion of chemical reaction equilibria is given by Eq. (4-296). For a system in which just a single reaction occurs, Eq. (4-361) becomes

$$n_i = n_{i0} + v_i \epsilon \quad \text{whence} \quad dn_i = v_i d\epsilon$$

Substitution for  $dn_i$  in Eq. (4-296) leads to

$$\sum_i v_i \mu_i = 0 \quad (4-362)$$

Generalization of this result to multiple reactions produces

$$\sum_i v_{i,j} \mu_i = 0 \quad j = \text{I, II, } \dots, r \quad (4-363)$$

**Standard Property Changes of Reaction** For the reaction

a *standard* property change is defined as the property change resulting when  $a$  mol of  $A$  and  $b$  mol of  $B$  in their *standard states at temperature*

## 4-36 THERMODYNAMICS

$T$  react to form  $l$  mol of  $L$  and  $m$  mol of  $M$  in their *standard states also at temperature  $T$* . A *standard state* of species  $i$  is its real or hypothetical state as a pure species at temperature  $T$  and at a standard state pressure  $P^\circ$ . The standard property change of reaction  $j$  is given the symbol  $\Delta M_j^\circ$  and its general mathematical definition is

$$\Delta M_j^\circ \equiv \sum_i \nu_{i,j} M_i^\circ \quad (4-364)$$

For species present as gases in the actual reactive system, the standard state is the pure *ideal gas* at pressure  $P^\circ$ . For liquids and solids, it is usually the state of pure real liquid or solid at  $P^\circ$ . The standard state pressure  $P^\circ$  is fixed at 100 kPa. Note that the standard states may represent different physical states for different species; any or all the species may be gases, liquids, or solids.

The most commonly used standard property changes of reaction are

$$\Delta G_j^\circ \equiv \sum_i \nu_{i,j} G_i^\circ = \sum_i \nu_{i,j} \mu_i^\circ \quad (4-365)$$

$$\Delta H_j^\circ \equiv \sum_i \nu_{i,j} H_i^\circ \quad (4-366)$$

$$\Delta C_{p,j}^\circ \equiv \sum_i \nu_{i,j} C_{p,i}^\circ \quad (4-367)$$

The standard Gibbs energy change of reaction  $\Delta G_j^\circ$  is used in the calculation of equilibrium compositions. The standard heat of reaction  $\Delta H_j^\circ$  is used in the calculation of the heat effects of chemical reaction, and the standard heat capacity change of reaction is used for extrapolating  $\Delta H_j^\circ$  and  $\Delta G_j^\circ$  with  $T$ . Numerical values for  $\Delta H_j^\circ$  and  $\Delta G_j^\circ$  are computed from tabulated formation data, and  $\Delta C_{p,j}^\circ$  is determined from empirical expressions for the  $T$  dependence of the  $C_{p,i}^\circ$  [see, e.g., Eq. (4-52)].

**Equilibrium Constants** For practical application, Eq. (4-363) must be reformulated. The initial step is elimination of the  $\mu_i$  in favor of fugacities. Equation (4-199) for species  $i$  in its standard state is subtracted from Eq. (4-202) for species  $i$  in the equilibrium mixture, giving

$$\mu_i = G_i^\circ + RT \ln \hat{a}_i \quad (4-368)$$

where by definition  $\hat{a}_i \equiv f_i/f_i^\circ$  and is called an *activity*. Substitution of this equation into Eq. (4-364) yields, upon rearrangement,

$$\sum_i [\nu_{i,j} (G_i^\circ + RT \ln \hat{a}_i)] = 0$$

$$\text{or} \quad \sum_i \nu_{i,j} G_i^\circ + RT \sum_i \ln \hat{a}_i^{\nu_{i,j}} = 0$$

$$\text{or} \quad \ln \prod_i \hat{a}_i^{\nu_{i,j}} = \frac{-\sum_i \nu_{i,j} G_i^\circ}{RT}$$

The right side of this equation is a function of temperature only for given reactions and given standard states. Convenience suggests setting it equal to  $\ln K_j$ , whence

$$\prod_i \hat{a}_i^{\nu_{i,j}} = K_j \quad \text{all } j \quad (4-369)$$

$$\text{where, by definition,} \quad K_j \equiv \exp\left(\frac{-\Delta G_j^\circ}{RT}\right) \quad (4-370)$$

Quantity  $K_j$  is the chemical reaction equilibrium constant for reaction  $j$ , and  $\Delta G_j^\circ$  is the corresponding standard Gibbs energy change of reaction [see Eq. (4-365)]. Although called a "constant,"  $K_j$  is a function of  $T$ , but only of  $T$ .

The activities in Eq. (4-369) provide the connection between the *equilibrium* states of interest and the *standard* states of the constituent species, for which data are presumed available. The standard states are always at the equilibrium temperature. Although the standard state need not be the same for all species, for a *particular* species it must be the state represented by both  $G_i^\circ$  and the  $f_i^\circ$  upon which activity  $\hat{a}_i$  is based.

The application of Eq. (4-369) requires explicit introduction of composition variables. For gas-phase reactions this is accomplished through the fugacity coefficient

$$\hat{a}_i \equiv \frac{\hat{f}_i}{f_i^\circ} = \frac{y_i \hat{\phi}_i P}{f_i^\circ}$$

However, the standard state for gases is the ideal gas state at the standard state pressure, for which  $f_i^\circ = P^\circ$ . Therefore,

$$\hat{a}_i = \frac{y_i \hat{\phi}_i P}{P^\circ}$$

and Eq. (4-369) becomes

$$\prod_i (y_i \hat{\phi}_i)^{\nu_{i,j}} \left(\frac{P}{P^\circ}\right)^{\sum_i \nu_{i,j}} = K_j \quad \text{all } j \quad (4-371)$$

where  $\nu_j \equiv \sum_i \nu_{i,j}$  and  $P^\circ$  is the standard state pressure of 100 kPa, expressed in the same units used for  $P$ . The  $y_i$ 's may be eliminated in favor of equilibrium values of the reaction coordinates  $\epsilon_j$  (see Example 6). Then, for fixed temperature Eqs. (4-371) relate the  $\epsilon_j$  to  $P$ . In principle, specification of the pressure allows solution for the  $\epsilon_j$ . However, the problem may be complicated by the dependence of the  $\hat{\phi}_i$  on composition, i.e., on the  $\epsilon_j$ . If the equilibrium mixture is assumed an ideal solution, then [Eq. (4-218)] each  $\hat{\phi}_i$  becomes  $\phi_i$ , the fugacity coefficient of pure species  $i$  at the mixture  $T$  and  $P$ . This quantity does not depend on composition and may be determined from experimental data, from a generalized correlation, or from an equation of state.

An important special case of Eq. (4-371) results for gas-phase reactions when the phase is assumed an ideal gas. In this event  $\hat{\phi}_i = 1$ , and

$$\prod_i (y_i)^{\nu_{i,j}} \left(\frac{P}{P^\circ}\right)^{\nu_j} = K_j \quad \text{all } j \quad (4-372)$$

In the general case the evaluation of the  $\hat{\phi}_i$  requires an iterative process. An initial step is to set each  $\hat{\phi}_i$  equal to unity and to solve the problem by Eq. (4-372). This provides a set of  $y_i$  values, allowing evaluation of the  $\hat{\phi}_i$  by, for example, Eq. (4-243) or (4-246). Equation (4-371) can then be solved for a new set of  $y_i$  values, with the process continued to convergence.

For liquid-phase reactions, Eq. (4-369) is modified by introduction of the activity coefficient  $\gamma_i = f_i/x_i f_i^\circ$ , where  $x_i$  is the liquid-phase mole fraction. The activity is then

$$\hat{a}_i \equiv \frac{\hat{f}_i}{f_i^\circ} = \gamma_i x_i \left(\frac{f_i}{f_i^\circ}\right)$$

Both  $f_i$  and  $f_i^\circ$  represent fugacity of pure liquid  $i$  at temperature  $T$ , but at pressures  $P$  and  $P^\circ$ , respectively. Except in the critical region, pressure has little effect on the properties of liquids, and the ratio  $f_i/f_i^\circ$  is often taken as unity. When this is not acceptable, this ratio is evaluated by the equation

$$\ln \frac{f_i}{f_i^\circ} = \frac{1}{RT} \int_{P^\circ}^P V_i dP \approx \frac{V_i(P - P^\circ)}{RT}$$

When the ratio  $f_i/f_i^\circ$  is taken as unity,  $\hat{a}_i = \gamma_i x_i$ , and Eq. (4-369) becomes

$$\prod_i (\gamma_i x_i)^{\nu_{i,j}} = K_j \quad \text{all } j \quad (4-373)$$

Here the difficulty is to determine the  $\gamma_i$ 's, which depend on the  $x_i$ 's. This problem has not been solved for the general case. Two courses are open: the first is experiment; the second, assumption of solution ideality. In the latter case,  $\gamma_i = 1$ , and Eq. (4-373) reduces to

$$\prod_i (x_i)^{\nu_{i,j}} = K_j \quad \text{all } j \quad (4-374)$$

the "law of mass action." The significant feature of Eqs. (4-372) and (4-374), the simplest expressions for gas- and liquid-phase reaction

equilibrium, is that the temperature-, pressure-, and composition-dependent terms are distinct and separate.

The effect of temperature on the equilibrium constant follows from Eq. (4-41) written for pure species  $j$  in its standard state (wherein the pressure  $P^\circ$  is fixed):

$$\frac{d(G_j^\circ/RT)}{dT} = \frac{-H_j^\circ}{RT^2}$$

With Eqs. (4-365) and (4-366) this equation easily extends to relate standard property changes of reaction:

$$\frac{d(\Delta G_j^\circ/RT)}{dT} = \frac{-\Delta H_j^\circ}{RT^2} \quad (4-375)$$

In view of Eq. (4-370) this may also be written as

$$\frac{d \ln K_j}{dT} = \frac{\Delta H_j^\circ}{RT^2} \quad (4-376)$$

For an endothermic reaction,  $\Delta H_j^\circ$  is positive and  $K_j$  increases with increasing  $T$ ; for an exothermic reaction, it is negative and  $K_j$  decreases with increasing  $T$ .

Because the standard state pressure is constant, Eq. (4-28) may be extended to relate standard properties of reaction, yielding

$$d\Delta H_j^\circ = \Delta C_{P_j}^\circ dT \quad \text{and} \quad d\Delta S_j^\circ = \Delta C_{P_j}^\circ \frac{dT}{T}$$

Integration of these equations from reference temperature  $T_0$  (usually 298.15 K) to temperature  $T$  gives

$$\Delta H^\circ = \Delta H_0^\circ + R \int_{T_0}^T \frac{\Delta C_P^\circ}{R} dT \quad (4-377)$$

$$\Delta S^\circ = \Delta S_0^\circ + R \int_{T_0}^T \frac{\Delta C_P^\circ}{R} \frac{dT}{T} \quad (4-378)$$

where for simplicity subscript  $j$  has been suppressed. The definition of  $G$  leads directly to  $\Delta G^\circ = \Delta H^\circ - T\Delta S^\circ$ . Combining this equation with Eqs. (4-370), (4-377), and (4-378) yields

$$\ln K = \frac{-\Delta G^\circ}{RT} = \frac{-\Delta H_0^\circ}{RT} - \frac{1}{T} \int_{T_0}^T \frac{\Delta C_P^\circ}{R} dT + \frac{\Delta S_0^\circ}{R} + \int_{T_0}^T \frac{\Delta C_P^\circ}{R} \frac{dT}{T}$$

Substituting  $\Delta S_0^\circ = (\Delta G_0^\circ - \Delta H_0^\circ)/T_0$ , rearranging, and defining  $\tau \equiv T/T_0$  give finally

$$\ln K = \frac{-\Delta G_0^\circ}{RT_0} + \frac{\Delta H_0^\circ}{RT_0} \left( \frac{\tau - 1}{\tau} \right) - \frac{1}{T} \int_{T_0}^T \frac{\Delta C_P^\circ}{R} dT + \int_{T_0}^T \frac{\Delta C_P^\circ}{R} \frac{dT}{T} \quad (4-379)$$

When heat capacity equations have the form of Eq. (4-52), the integrals are evaluated by equations of exactly the form of Eqs. (4-53) and (4-54), but with parameters  $A$ ,  $B$ ,  $C$ , and  $D$  replaced by  $\Delta A$ ,  $\Delta B$ ,  $\Delta C$ , and  $\Delta D$ , in accord with Eq. (4-364). Thus for the ideal gas standard state

$$\int_{T_0}^T \frac{\Delta C_P^\circ}{R} dT = \Delta A T_0(\tau - 1) + \frac{\Delta B}{2} T_0^2(\tau^2 - 1) + \frac{\Delta C}{3} T_0^3(\tau^3 - 1) + \frac{\Delta D}{T_0} \left( \frac{\tau - 1}{\tau} \right) \quad (4-380)$$

$$\int_{T_0}^T \frac{\Delta C_P^\circ}{R} \frac{dT}{T} = \Delta A \ln \tau + \left[ \Delta B T_0 + \left( \Delta C T_0^2 + \frac{\Delta D}{\tau^2 T_0^2} \right) \left( \frac{\tau + 1}{2} \right) \right] (\tau - 1) \quad (4-381)$$

Equations (4-379) through (4-381) together allow an equation to be written for  $\ln K$  as a function of  $T$  for any reaction for which appropriate data are available.

In the more extensive compilations of data, values of  $\Delta G^\circ$  and  $\Delta H^\circ$  for formation reactions are given for a wide range of temperatures, rather than just at the reference temperature  $T_0 = 298.15$  K. [See in particular *TRC Thermodynamic Tables—Hydrocarbons* and *TRC Thermodynamic Tables—Non-hydrocarbons*, serial publications of the Thermodynamics Research Center, Texas A & M Univ. System, College Station, Tex.; "The NBS Tables of Chemical Thermodynamic Properties," *J. Phys. Chem. Ref. Data* **11**, supp. 2 (1982).] Where data are lacking, methods of estimation are available; these are reviewed by Poling, Prausnitz, and O'Connell, *The Properties of Gases and Liquids*, 5th ed., chap. 6, McGraw-Hill, New York, 2000. For an estimation procedure based on molecular structure, see Constantinou and Gani, *Fluid Phase Equilib.* **103**: 11–22 (1995). See also Sec. 2.

**Example 6: Single-Reaction Equilibrium** The hydrogenation of benzene to produce cyclohexane by the reaction

is carried out over a catalyst formulated to repress side reactions. Operating conditions cover a pressure range from 10 to 35 bar and a temperature range from 450 to 670 K. Reaction rate increases with increasing  $T$ , but because the reaction is exothermic the equilibrium conversion decreases with increasing  $T$ . A comprehensive study of the effect of operating variables on the chemical equilibrium of this reaction has been published by J. Carrero-Mantilla and M. Llano-Restrepo, *Fluid Phase Equilib.* **219**: 181–193 (2004). Presented here are calculations for a single set of operating conditions, namely,  $T = 600$  K,  $P = 15$  bar, and a molar feed ratio  $\text{H}_2/\text{C}_6\text{H}_6 = 3$ , the stoichiometric value. For these conditions we determine the fractional conversion of benzene to cyclohexane. Carrero-Mantilla and Llano-Restrepo express  $\ln K$  as a function of  $T$  by an equation which for 600 K yields the value  $K = 0.02874$ .

A feed stream containing 3 mol  $\text{H}_2$  for each 1 mol  $\text{C}_6\text{H}_6$  is the basis of calculation, and for this single reaction, Eq. (4-361) becomes  $n_i = n_{i0} + \nu_{ie}$ , yielding

$$\begin{aligned} n_B &= 1 - \epsilon && \text{benzene} \\ n_{\text{H}_2} &= 3 - 3\epsilon && \text{hydrogen} \\ n_C &= \epsilon && \text{cyclohexane} \\ \sum_i n_i &= 4 - 3\epsilon \end{aligned}$$

Each mole fraction is therefore given by  $y_i = n_i/(4 - 3\epsilon)$ .

Assume first that the equilibrium mixture is an ideal gas, and apply Eq. (4-372), written for a single reaction, with subscript  $j$  omitted and  $\nu = -3$ :

$$\prod_i y_i^{\nu_i} \left( \frac{P}{P^\circ} \right)^\nu = \frac{\epsilon}{4 - 3\epsilon} = \left( \frac{1 - \epsilon}{4 - 3\epsilon} \right)^3 \left( \frac{15}{1} \right)^{-3} = K = 0.02874$$

$$\text{whence} \quad \frac{\epsilon}{1 - \epsilon} \left( \frac{4 - 3\epsilon}{3 - 3\epsilon} \right)^3 (15)^{-3} = 0.02874 \quad \text{and} \quad \epsilon = 0.815$$

Thus, the assumption of ideal gases leads to a calculated conversion of 81.5 percent.

An alternative assumption is that the equilibrium mixture is an ideal solution. This requires application of Eq. (4-371). However, in the case of an ideal solution Eq. (4-218) indicates that  $\hat{\phi}_i^s = \phi_i$ , in which case Eq. (4-371) for a single reaction becomes

$$\prod_i (y_i \phi_i)^{\nu_i} \left( \frac{P}{P^\circ} \right)^\nu = K$$

For purposes of illustration we evaluate the pure-species fugacity coefficients by Eq. (4-206), written here as

$$\phi_i = \exp(B_i^0 + \omega B_i^1) \frac{P_i}{T_i}$$

The following table shows values for the various quantities in this equation. Note that  $T_i$  and  $P_i$  for hydrogen are effective values as calculated by Eqs. (4-124) and (4-125) and used with  $\omega = 0$ .

|                           | $T_c$ | $T_r$  | $P_c$ | $P_r$ | $\omega$ | $B^0$   | $B^1$ | $\phi$ |
|---------------------------|-------|--------|-------|-------|----------|---------|-------|--------|
| $\text{C}_6\text{H}_6$    | 562.2 | 1.067  | 48.98 | 0.306 | 0.21     | -0.2972 | 0.008 | 0.919  |
| $\text{H}_2$              | 42.8  | 14.009 | 19.78 | 0.758 | 0.00     | 0.0768  | 0.139 | 1.004  |
| $\text{C}_6\text{H}_{12}$ | 553.6 | 1.084  | 40.73 | 0.368 | 0.21     | -0.2880 | 0.016 | 0.908  |

## 4-38 THERMODYNAMICS

The equilibrium equation now becomes:

$$\prod_i (y_i \phi_i)^{\nu_i} \left( \frac{P}{P^\circ} \right)^{\sum \nu_i} = \frac{\frac{\varepsilon}{4-3\varepsilon} 0.919}{\left( \frac{1-\varepsilon}{4-3\varepsilon} 0.908 \right) \left( \frac{3-3\varepsilon}{4-3\varepsilon} 1.004 \right)^3} \left( \frac{15}{1} \right)^{-3} = K = 0.02874$$

Solution yields  $\varepsilon = 0.816$

This result is hardly different from that based on the ideal gas assumption. The fugacity coefficients in the equilibrium equation clearly cancel one another. This is not uncommon in reaction equilibrium calculations, as there are always products and reactions, making the ideal gas assumption far more useful than might be expected.

Carrero-Mantilla and Llano-Restrep present results for a wide range of conditions, both for the ideal gas assumption and for calculations wherein  $\phi_i$  values are determined from the Soave-Redlich-Kwong equation of state. In no case are these calculated conversions significantly divergent.

**Complex Chemical Reaction Equilibria** When the composition of an equilibrium mixture is determined by a number of simultaneous reactions, calculations based on equilibrium constants become complex and tedious. A more direct procedure (and one suitable for general computer solution) is based on minimization of the total Gibbs energy  $G^t$  in accord with Eq. (4-293). The treatment here is limited to gas-phase reactions for which the problem is to find the equilibrium composition for given  $T$  and  $P$  and for a given initial feed.

1. Formulate the constraining material-balance equations, based on conservation of the total number of atoms of each *element* in a system comprised of  $w$  elements. Let subscript  $k$  identify a particular atom, and define  $A_k$  as the total number of atomic masses of the  $k$ th element in the feed. Further, let  $a_{ik}$  be the number of atoms of the  $k$ th element present in each molecule of chemical species  $i$ . The material balance for element  $k$  is then

$$\sum_i n_i a_{ik} = A_k \quad k = 1, 2, \dots, w \quad (4-382)$$

or 
$$\sum_i n_i a_{ik} - A_k = 0 \quad k = 1, 2, \dots, w$$

2. Multiply each element balance by  $\lambda_k$ , a Lagrange multiplier:

$$\lambda_k \left( \sum_i n_i a_{ik} - A_k \right) = 0 \quad k = 1, 2, \dots, w$$

Summed over  $k$ , these equations give

$$\sum_k \lambda_k \left( \sum_i n_i a_{ik} - A_k \right) = 0$$

3. Form a function  $F$  by addition of this sum to  $G^t$ :

$$F = G^t + \sum_k \lambda_k \left( \sum_i n_i a_{ik} - A_k \right)$$

Function  $F$  is identical with  $G^t$ , because the summation term is zero. However, the partial derivatives of  $F$  and  $G^t$  with respect to  $n_i$  are different, because function  $F$  incorporates the constraints of the material balances.

4. The minimum value of both  $F$  and  $G^t$  is found when the partial derivatives of  $F$  with respect to  $n_i$  are set equal to zero:

$$\left( \frac{\partial F}{\partial n_i} \right)_{T,P,n_j} = \left( \frac{\partial G^t}{\partial n_i} \right)_{T,P,n_j} + \sum_k \lambda_k a_{ik} = 0$$

The first term on the right is the definition of the chemical potential; therefore,

$$\mu_i + \sum_k \lambda_k a_{ik} = 0 \quad i = 1, 2, \dots, N \quad (4-383)$$

However, the chemical potential is given by Eq. (4-368); for gas-phase reactions and standard states as the pure ideal gases at  $P^\circ$ , this equation becomes

$$\mu_i = G_i^\circ + RT \ln \frac{\hat{f}_i}{P^\circ}$$

If  $G_i^\circ$  is arbitrarily set equal to zero for all *elements* in their standard states, then for compounds  $G_i^\circ = \Delta G_{f,i}^\circ$ , the standard Gibbs energy change of formation of species  $i$ . In addition, the fugacity is eliminated—in favor of the fugacity coefficient by Eq. (4-204),  $\hat{f}_i = y_i \hat{\phi}_i P$ . With these substitutions, the equation for  $\mu_i$  becomes

$$\mu_i = \Delta G_{f,i}^\circ + RT \ln \frac{y_i \hat{\phi}_i P}{P^\circ}$$

Combination with Eq. (4-383) gives

$$\Delta G_{f,i}^\circ + RT \ln \frac{y_i \hat{\phi}_i P}{P^\circ} + \sum_k \lambda_k a_{ik} = 0 \quad i = 1, 2, \dots, N \quad (4-384)$$

If species  $i$  is an element,  $\Delta G_{f,i}^\circ$  is zero. There are  $N$  equilibrium equations [Eqs. (4-384)], one for each chemical species, and there are  $w$  material balance equations [Eqs. (4-382)], one for each element—a total of  $N + w$  equations. The unknowns in these equations are the  $n_i$ 's (note that  $y_i = n_i / \sum n_i$ ), of which there are  $N$ , and the  $\lambda_i$ 's, of which there are  $w$ —a total of  $N + w$  unknowns. Thus the number of equations is sufficient for the determination of all unknowns.

Equation (4-384) is derived on the presumption that the set  $\{\hat{\phi}_i\}$  is known. If the phase is an ideal gas, then each  $\hat{\phi}_i$  is unity. If the phase is an ideal solution, each  $\hat{\phi}_i$  becomes  $\phi_i$  and can at least be estimated. For real gases, each  $\hat{\phi}_i$  is a function of the set  $\{y_i\}$ , the quantities being calculated. Thus an iterative procedure is indicated, initiated with each  $\hat{\phi}_i$  set equal to unity. Solution of the equations then provides a preliminary set  $\{y_i\}$ . For low pressures or high temperatures this result is usually adequate. Where it is not satisfactory, an equation of state with the preliminary set  $\{y_i\}$  gives a new and more nearly correct set  $\{\hat{\phi}_i\}$  for use in Eq. (4-384). Then a new set  $\{y_i\}$  is determined. The process is repeated to convergence. All calculations are well suited to computer solution.

In this procedure, the question of what chemical reactions are involved never enters directly into any of the equations. However, the choice of a set of species is entirely equivalent to the choice of a set of independent reactions among the species. In any event, a set of species or an equivalent set of independent reactions must always be assumed, and different assumptions produce different results.

A detailed example of a complex gas-phase equilibrium calculation is given by Smith, Van Ness, and Abbott [*Introduction to Chemical Engineering Thermodynamics*, 5th ed., Example 15.13, pp. 602–604; 6th ed., Example 13.14, pp. 511–513; 7th ed., Example 13.14, pp. 527–528, McGraw-Hill, New York (1996, 2001, 2005)]. General application of the method to multicomponent, multiphase systems is treated by Iglesias-Silva et al. [*Fluid Phase Equilib.* **210**: 229–245 (2003)] and by Sotyan, Ghajar, and Gasem [*Ind. Eng. Chem. Res.* **42**: 3786–3801 (2003)].

## THERMODYNAMIC ANALYSIS OF PROCESSES

Real irreversible processes can be subjected to thermodynamic analysis. The goal is to calculate the efficiency of energy use or production and to show how wasted energy is apportioned among the steps of a process. The treatment here is limited to steady-state steady-flow processes, because of their predominance in chemical technology.

### CALCULATION OF IDEAL WORK

In any steady-state steady-flow process *requiring* work, a minimum amount must be expended to bring about a specific change of state in the flowing fluid. In a process *producing* work, a maximum amount is

attainable for a specific change of state in the flowing fluid. In either case, the limiting value obtains when the specific change of state is accomplished *completely reversibly*. The implications of this requirement are that

1. The process is internally reversible within the control volume.
2. Heat transfer external to the control volume is reversible.

The second item means that heat exchange between system and surroundings must occur at the temperature of the surroundings, presumed to constitute a heat reservoir at a constant and uniform temperature  $T_\sigma$ . This may require Carnot engines or heat pumps internal to the system that provide for the reversible transfer of heat from the temperatures of the flowing fluid to that of the surroundings. Because Carnot engines and heat pumps are cyclic, they undergo no net change of state.

These conditions are implicit in the entropy balance of Eq. (4-156) when  $\dot{S}_C = 0$ . If in addition there is but a single surroundings temperature  $T_\sigma$ , this equation becomes

$$\Delta(S\dot{m})_{fs} - \frac{\dot{Q}}{T_\sigma} = 0 \quad (4-385)$$

The energy balance for a steady-state steady-flow process as given by Eq. (4-150) is

$$\Delta\left[\left(H + \frac{1}{2}u^2 + zg\right)\dot{m}\right]_{fs} = \dot{Q} + \dot{W}_s \quad (4-150)$$

Combining this equation with Eq. (4-385) to eliminate  $\dot{Q}$  yields

$$\Delta\left[\left(H + \frac{1}{2}u^2 + zg\right)\dot{m}\right]_{fs} = T_\sigma \Delta(S\dot{m})_{fs} + \dot{W}_s(\text{rev})$$

where  $\dot{W}_s(\text{rev})$  indicates that the shaft work is for a completely reversible process. This work is called the *ideal work*  $\dot{W}_{\text{ideal}}$ . Thus

$$\dot{W}_{\text{ideal}} = \Delta\left[\left(H + \frac{1}{2}u^2 + zg\right)\dot{m}\right]_{fs} - T_\sigma \Delta(S\dot{m})_{fs} \quad (4-386)$$

In most applications to chemical processes, the kinetic and potential energy terms are negligible compared with the others; in this event Eq. (4-386) is written as

$$\dot{W}_{\text{ideal}} = \Delta(H\dot{m})_{fs} - T_\sigma \Delta(S\dot{m})_{fs} \quad (4-387)$$

For the special case of a single stream flowing through the system, Eq. (4-387) becomes

$$\dot{W}_{\text{ideal}} = \dot{m}(\Delta H - T_\sigma \Delta S) \quad (4-388)$$

Division by  $\dot{m}$  puts this equation on a unit-mass basis:

$$w_{\text{ideal}} = \Delta H - T_\sigma \Delta S \quad (4-389)$$

A completely reversible process is hypothetical, devised solely to find the ideal work associated with a given change of state. Its only connection with an actual process is that it brings about the same change of state as the actual process, allowing comparison of the actual work of a process with the work of the hypothetical reversible process.

Equations (4-386) through (4-389) give the work of a completely reversible process associated with given property changes in the flowing streams. When the same property changes occur in an actual process, the actual work  $\dot{W}_s$  (or  $W_s$ ) is given by an energy balance, and comparison can be made of the actual work with the ideal work. When  $\dot{W}_{\text{ideal}}$  (or  $W_{\text{ideal}}$ ) is positive, it is the *minimum work required* to bring about a given change in the properties of the flowing streams, and it is smaller than  $\dot{W}_s$ . In this case a thermodynamic efficiency  $\eta_t$  is defined as the ratio of the ideal work to the actual work:

$$\eta_t(\text{work required}) = \frac{\dot{W}_{\text{ideal}}}{\dot{W}_s} \quad (4-390)$$

When  $\dot{W}_{\text{ideal}}$  (or  $W_{\text{ideal}}$ ) is negative,  $|\dot{W}_{\text{ideal}}|$  is the *maximum work obtainable* from a given change in the properties of the flowing streams, and it is larger than  $|\dot{W}_s|$ . In this case, the thermodynamic efficiency is defined as the ratio of the actual work to the ideal work:

$$\eta_t(\text{work produced}) = \frac{\dot{W}_s}{\dot{W}_{\text{ideal}}} \quad (4-391)$$

## LOST WORK

Work that is wasted as the result of irreversibilities in a process is called *lost work*  $\dot{W}_{\text{lost}}$ , and it is defined as the difference between the actual work of a process and the ideal work for the process. Thus by definition,

$$W_{\text{lost}} \equiv W_s - W_{\text{ideal}} \quad (4-392)$$

The rate form is

$$\dot{W}_{\text{lost}} \equiv \dot{W}_s - \dot{W}_{\text{ideal}} \quad (4-393)$$

The actual work rate comes from Eq. (4-150):

$$\dot{W}_s = \Delta\left[\left(H + \frac{1}{2}u^2 + zg\right)\dot{m}\right]_{fs} - \dot{Q}$$

Subtracting the ideal work rate as given by Eq. (4-386) yields

$$\dot{W}_{\text{lost}} = T_\sigma \Delta(S\dot{m})_{fs} - \dot{Q} \quad (4-394)$$

For the special case of a single stream flowing through the control volume,

$$\dot{W}_{\text{lost}} = \dot{m}T_\sigma \Delta S - \dot{Q} \quad (4-395)$$

Division of this equation by  $\dot{m}$  gives

$$w_{\text{lost}} = T_\sigma \Delta S - Q \quad (4-396)$$

where the basis is now a unit amount of fluid flowing through the control volume.

The total rate of entropy generation (in both system and surroundings) as a result of a process is

$$\dot{S}_C = \Delta(S\dot{m})_{fs} - \frac{\dot{Q}}{T_\sigma} \quad (4-397)$$

Division by  $\dot{m}$  provides an equation based on a unit amount of fluid flowing through the control volume:

$$s_C = \Delta S - \frac{Q}{T_\sigma} \quad (4-398)$$

Equations (4-397) and (4-398) are special cases of Eqs. (4-156) and (4-157).

Multiplication of Eq. (4-397) by  $T_\sigma$  gives

$$T_\sigma \dot{S}_C = T_\sigma \Delta(S\dot{m})_{fs} - \dot{Q}$$

Because the right sides of this equation and of Eq. (4-394) are identical, it follows that

$$\dot{W}_{\text{lost}} = T_\sigma \dot{S}_C \quad (4-399)$$

For flow on the basis of a unit amount of fluid, this becomes

$$w_{\text{lost}} = T_\sigma s_C \quad (4-400)$$

Because the second law of thermodynamics requires

$$\dot{S}_C \geq 0 \quad \text{and} \quad s_C \geq 0$$

therefore

$$\dot{W}_{\text{lost}} \geq 0 \quad \text{and} \quad w_{\text{lost}} \geq 0$$

When a process is completely reversible, the equality holds and the lost work is zero. For irreversible processes the inequality holds, and the lost work, i.e., the energy that becomes unavailable for work, is positive. The engineering significance of this result is clear: The greater the irreversibility of a process, the greater the rate of entropy generation and the greater the amount of energy that becomes unavailable for work. Thus every irreversibility carries with it a price.

## ANALYSIS OF STEADY-STATE STEADY-FLOW PROCESSES

Many processes consist of a number of steps, and lost-work calculations are then made for each step separately. Writing Eq. (4-399) for each step of the process and summing give

$$\sum \dot{W}_{\text{lost}} = T_\sigma \sum \dot{S}_C$$

## 4-40 THERMODYNAMICS

Dividing Eq. (4-399) by this result yields

$$\frac{\dot{W}_{\text{lost}}}{\sum \dot{W}_{\text{lost}}} = \frac{\dot{S}_G}{\sum \dot{S}_G}$$

Thus an analysis of the lost work, made by calculation of the fraction that each individual lost-work term represents of the total lost work, is the same as an analysis of the rate of entropy generation, made by expressing each individual entropy generation term as a fraction of the sum of all entropy generation terms.

An alternative to the lost-work or entropy generation analysis is a work analysis. This is based on Eq. (4-393), written as

$$\sum \dot{W}_{\text{lost}} = \dot{W}_s - \dot{W}_{\text{ideal}} \quad (4-401)$$

For a work-requiring process, all these work quantities are positive and  $\dot{W}_s > \dot{W}_{\text{ideal}}$ . The preceding equation is then expressed as

$$\dot{W}_s = \dot{W}_{\text{ideal}} + \sum \dot{W}_{\text{lost}} \quad (4-402)$$

A work analysis then gives each of the individual work terms in the summation on the right as a fraction of  $\dot{W}_s$ .

For a work-producing process,  $\dot{W}_s$  and  $\dot{W}_{\text{ideal}}$  are negative, and  $|\dot{W}_{\text{ideal}}| > |\dot{W}_s|$ . Equation (4-401) in this case is best written as

$$|\dot{W}_{\text{ideal}}| = |\dot{W}_s| + \sum \dot{W}_{\text{lost}} \quad (4-403)$$

A work analysis here expresses each of the individual work terms on the right as a fraction of  $|\dot{W}_{\text{ideal}}|$ . A work analysis cannot be carried out in the case where a process is so inefficient that  $\dot{W}_{\text{ideal}}$  is negative, indicating that the process should produce work; but  $\dot{W}_s$  is positive, indicating that the process in fact requires work. A lost-work or entropy generation analysis is always possible.

**Example 7: Lost-Work Analysis** A work analysis follows for a simple Linde system for the separation of air into gaseous oxygen and nitrogen, as depicted in Fig. 4-10. Table 4-8 lists a set of operating conditions for the numbered points of the diagram. Heat leaks into the column of 147 J/mol of entering air and into the exchanger of 70 J/mol of entering air have been assumed. Take  $T_0 = 300$  K.

The basis for analysis is 1 mol of entering air, assumed to contain 79 mol % N<sub>2</sub> and 21 mol % O<sub>2</sub>. By a material balance on the nitrogen, 0.79 = 0.9148 x, whence

$$\begin{aligned} x &= 0.8636 \text{ mol of nitrogen product} \\ 1 - x &= 0.1364 \text{ mol of oxygen product} \end{aligned}$$

**Calculation of ideal work:** If changes in kinetic and potential energies are neglected, Eq. (4-387) is applicable. From the tabulated data,

$$\begin{aligned} \Delta(H\dot{m})_{\text{is}} &= (13,460)(0.1364) + (12,074)(0.8636) - (12,407)(1) = -144 \text{ J} \\ \Delta(S\dot{m})_{\text{is}} &= (118.48)(0.1364) + (114.34)(0.8636) - (117.35)(1) = -2.4453 \text{ J/K} \end{aligned}$$

FIG. 4-10 Diagram of simple Linde system for air separation.

TABLE 4-8 States and Values of Properties for the Process of Fig. 4-10\*

| Point | P, bar | T, K  | Composition           | State           | H, J/mol | S, J/(mol·K) |
|-------|--------|-------|-----------------------|-----------------|----------|--------------|
| 1     | 55.22  | 300   | Air                   | Superheated     | 12,046   | 82.98        |
| 2     | 1.01   | 295   | Pure O <sub>2</sub>   | Superheated     | 13,460   | 118.48       |
| 3     | 1.01   | 295   | 91.48% N <sub>2</sub> | Superheated     | 12,074   | 114.34       |
| 4     | 55.22  | 147.2 | Air                   | Superheated     | 5,850    | 52.08        |

| 6     | 1.01   | 90    | Pure O <sub>2</sub>   | Saturated vapor | 7,485    | 83.69        |
| 7     | 1.01   | 300   | Air                   | Superheated     | 12,407   | 117.35       |

\*Properties on the basis of Miller and Sullivan, U.S. Bur. Mines Tech. Pap. 424 (1928).

Thus, by Eq. (4-387),

$$\dot{W}_{\text{ideal}} = -144 - (300)(-2.4453) = 589.6 \text{ J}$$

**Calculation of actual work of compression:** For simplicity, the work of compression is calculated by the equation for an ideal gas in a three-stage reciprocating machine with complete intercooling and with isentropic compression in each stage. The work so calculated is assumed to represent 80 percent of the actual work. The following equation may be found in any number of textbooks on thermodynamics:

$$\dot{W}_s = \frac{n\gamma RT_1}{0.8(\gamma - 1)} \left[ \left( \frac{P_2}{P_1} \right)^{(\gamma - 1)/n\gamma} - 1 \right]$$

where  $n$  = number of stages, here taken as 3

$\gamma$  = ratio of heat capacities, here taken as 1.4

$T_1$  = initial absolute temperature, equal to 300 K

$P_2/P_1$  = overall pressure ratio, equal to 54.5

$R$  = universal gas constant, equal to 8.314 J/(mol·K)

The efficiency factor of 0.8 is already included in the equation. Substitution of the remaining values gives

$$\dot{W}_s = \frac{(3)(1.4)(8.314)(300)}{(0.8)(0.4)} \left[ (54.5)^{0.4/(3)(1.4)} - 1 \right] = 15,171 \text{ J}$$

The heat transferred to the surroundings during compression as a result of intercooling and aftercooling to 300 K is found from the first law:

$$\dot{Q} = \dot{m}(\Delta H) - \dot{W}_s = (12,046 - 12,407) - 15,171 = -15,532 \text{ J}$$

**Calculation of lost work:** Equation (4-394) may be applied to each of the major units of the process. For the compressor/cooler,

$$\dot{W}_{\text{lost}} = (300)[(82.98)(1) - (117.35)(1)] - (-15,532) = 5221.0 \text{ J}$$

For the exchanger,

$$\begin{aligned} \dot{W}_{\text{lost}} &= (300)[(118.48)(0.1364) + (114.34)(0.8636) + (52.08)(1) \\ &\quad - (75.82)(0.8636) - (83.69)(0.1364) - (82.98)(1)] - 70 \\ &= 2063.4 \text{ J} \end{aligned}$$

Finally, for the rectifier,

$$\dot{W}_{\text{lost}} = (300)[(75.82)(0.8636) + (83.69)(0.1364) - (52.08)(1)] - 147 = 7297.0 \text{ J}$$

**Work analysis:** Because the process requires work, Eq. (4-402) is appropriate for a work analysis. The various terms of this equation appear as entries in the following table and are on the basis of 1 mol of entering air.

|                          |                   |            | % of $\dot{W}_s$ |
|--------------------------|-------------------|------------|------------------|
| $\dot{W}_{\text{ideal}}$ |                   | 589.6 J    | 3.9              |
| $\dot{W}_{\text{lost}}$  | Compressor/cooler | 5,221.0 J  | 34.4             |
| $\dot{W}_{\text{lost}}$  | Exchanger         | 2,063.4 J  | 13.6             |
| $\dot{W}_{\text{lost}}$  | Rectifier         | 7,297.0 J  | 48.1             |
| $\dot{W}_s$              |                   | 15,171.0 J | 100.0            |

The thermodynamic efficiency of this process as given by Eq. (4-390) is only 3.9 percent. Significant inefficiencies reside with each of the primary units of the process.

## MODES OF HEAT TRANSFER

Heat is energy transferred due to a difference in temperature. There are three modes of heat transfer: conduction, convection, and radiation. All three may act at the same time. Conduction is the transfer of energy between adjacent particles of matter. It is a local phenomenon and can only occur through matter. Radiation is the transfer of energy from a point of higher temperature to a point of lower energy by electromagnetic radiation. Radiation can act at a distance through transparent media and vacuum. Convection is the transfer of energy by conduction and radiation in moving, fluid media. The motion of the fluid is an essential part of convective heat transfer.

## HEAT TRANSFER BY CONDUCTION

### FOURIER'S LAW

The heat flux due to conduction in the  $x$  direction is given by Fourier's law

$$\dot{Q} = -kA \frac{dT}{dx} \quad (5-1)$$

where  $\dot{Q}$  is the rate of heat transfer (W),  $k$  is the thermal conductivity [W/(m·K)],  $A$  is the area perpendicular to the  $x$  direction, and  $T$  is temperature (K). For the homogeneous, one-dimensional plane shown in Fig. 5-1a, with constant  $k$ , the integrated form of (5-1) is

$$\dot{Q} = kA \frac{T_1 - T_2}{\Delta x} \quad (5-2)$$

where  $\Delta x$  is the thickness of the plane. Using the thermal circuit shown in Fig. 5-1b, Eq. (5-2) can be written in the form

$$\dot{Q} = \frac{T_1 - T_2}{\Delta x/kA} = \frac{T_1 - T_2}{R} \quad (5-3)$$

where  $R$  is the thermal resistance (K/W).

**FIG. 5-1** Steady, one-dimensional conduction in a homogeneous planar wall with constant  $k$ . The thermal circuit is shown in (b) with thermal resistance  $\Delta x/(kA)$ .

### THERMAL CONDUCTIVITY

The thermal conductivity  $k$  is a transport property whose value for a variety of gases, liquids, and solids is tabulated in Sec. 2. Section 2 also provides methods for predicting and correlating vapor and liquid thermal conductivities. The thermal conductivity is a function of temperature, but the use of constant or averaged values is frequently sufficient. Room temperature values for air, water, concrete, and copper are 0.026, 0.61, 1.4, and 400 W/(m·K). Methods for estimating contact resistances and the thermal conductivities of composites and insulation are summarized by Gebhart, *Heat Conduction and Mass Diffusion*, McGraw-Hill, 1993, p. 399.

### STEADY-STATE CONDUCTION

**One-Dimensional Conduction** In the absence of energy source terms,  $\dot{Q}$  is constant with distance, as shown in Fig. 5-1a. For steady conduction, the integrated form of (5-1) for a planar system with constant  $k$  and  $A$  is Eq. (5-2) or (5-3). For the general case of variables  $k$  ( $k$  is a function of temperature) and  $A$  (cylindrical and spherical systems with radial coordinate  $r$ , as sketched in Fig. 5-2), the average heat-transfer area and thermal conductivity are defined such that

$$\dot{Q} = \bar{kA} \frac{T_1 - T_2}{\Delta x} = \frac{T_1 - T_2}{R} \quad (5-4)$$

For a thermal conductivity that depends linearly on  $T$ ,

$$k = k_0(1 + \gamma T) \quad (5-5)$$

**FIG. 5-2** The hollow sphere or cylinder.

**5-4 HEAT AND MASS TRANSFER**

**Nomenclature and Units—Heat Transfer by Conduction, by Convection, and with Phase Change**

| Symbol        | Definition  | SI units                     | Symbol              | Definition   | SI units            |
|---------------|---|------------------------------|---------------------|--|---------------------|
| $A$           | Area for heat transfer  | $m^2$                        | $Ra_x$              | Rayleigh number, $\beta \Delta T g x^3 / \nu \alpha$   |                     |
| $A_c$         | Cross-sectional area  | $m^2$                        | $Re_D$              | Reynolds number, $GD/\mu$  |                     |
| $A_f$         | Area for heat transfer for finned portion of tube   | $m^2$                        | $S$                 | Volumetric source term   | $W/m^3$             |
| $A_i$         | Inside area of tube   |                              | $S$                 | Cross-sectional area   | $m^2$               |
| $A_o$         | External area of bare, unfinned tube  | $m^2$                        | $S_1$               | Fourier spatial function   |                     |
| $A_{of}$      | External area of tube before tubes are attached = $A_o$   |                              | $t$                 | Time   | s                   |
| $A_T$         | Total external area of finned tube  | $m^2$                        | $t_{sv}$            | Saturated-vapor temperature  | K                   |
| $A_{uf}$      | Area for heat transfer for unfinned portion of finned tube  | $m^2$                        | $t_s$               | Surface temperature  | K                   |
| $A_1$         | First Fourier coefficient   |                              | $T$                 | Temperature  | K or °C             |
| $a_c$         | Cross-sectional area of fin   | $m^2$                        | $T_b$               | Bulk or mean temperature at a given cross section  | K                   |
| $b$           | Geometry; $b = 1$ , plane; $b = 2$ , cylinder; $b = 3$ , sphere   |                              | $\bar{T}_b$         | Bulk mean temperature, $(T_{b,in} + T_{b,out})/2$  | K                   |
| $b_f$         | Height of fin   | m                            | $T_C$               | Temperature of cold surface in enclosure   | K                   |
| $B_1$         | First Fourier coefficient   |                              | $T_f$               | Film temperature, $(T_s + T_\infty)/2$   | K                   |
| Bi            | Biot number, $hR/k$   |                              | $T_H$               | Temperature of hot surface in enclosure  | K                   |
| $c$           | Specific heat   | J/(kg·K)                     | $T_i$               | Initial temperature  | K                   |
| $c_p$         | Specific heat, constant pressure  | J/(kg·K)                     | $T_e$               | Temperature of free stream   | K                   |
| $D$           | Diameter  | m                            | $T_s$               | Temperature of surface   | K                   |
| $D_i$         | Inner diameter  | m                            | $T_\infty$          | Temperature of fluid in contact with a solid surface   | K                   |
| $D_o$         | Outer diameter  | m                            | $U$                 | Overall heat-transfer coefficient  | $W/(m^2 \cdot K)$   |
| $f$           | Fanning friction factor   |                              | $V$                 | Volume   | $m^3$               |
| Fo            | Dimensionless time or Fourier number, $\alpha t/R^2$  |                              | $V_F$               | Velocity of fluid approaching a bank of finned tubes   | m/s                 |
| $g_c$         | Conversion factor   | 1.0 kg·m/(N·s <sup>2</sup> ) | $V_\infty$          | Velocity upstream of tube bank   | m/s                 |
| $g$           | Acceleration of gravity, 9.81 m/s <sup>2</sup>  | $m^2/s$                      | $W_F$               | Total rate of vapor condensation on one tube   | kg/s                |
| $G$           | Mass velocity, $\dot{m}/A_c$ ; $G_e$ for vapor mass velocity  | kg/(m <sup>2</sup> ·s)       | $x$                 | Cartesian coordinate direction, characteristic dimension of a surface, or distance from entrance | m                   |
| $G_{max}$     | Mass velocity through minimum free area between rows of tubes normal to the fluid stream                                | kg/(m <sup>2</sup> ·s)       | $x$                 | Vapor quality, $x_i$ for inlet and $x_o$ for outlet  |                     |
| Gz            | Graetz number = Re Pr   |                              | $\tilde{z}_p$       | Distance (perimeter) traveled by fluid across fin  | m                   |
| $\bar{h}$     | Heat-transfer coefficient   | $W/(m^2 \cdot K)$            | Greek Symbols       |  |                     |
| $h$           | Average heat-transfer coefficient   | $W/(m^2 \cdot K)$            | $\alpha$            | Thermal diffusivity, $k/(\rho c)$  | $m^2/s$             |
| $h_f$         | Heat-transfer coefficient for finned-tube exchangers based on total external surface                                    | $W/(m^2 \cdot K)$            | $\beta$             | Volumetric coefficient of expansion  | $K^{-1}$            |
| $h_f$         | Outside heat-transfer coefficient calculated for a bare tube for use with Eq. (5-73)                                    | $W/(m^2 \cdot K)$            | $\beta'$            | Contact angle between a bubble and a surface   | °                   |
| $h_{fi}$      | Effective outside heat-transfer coefficient based on inside area of a finned tube                                       | $W/(m^2 \cdot K)$            | $\Gamma$            | Mass flow rate per unit length perpendicular to flow   | kg/(m·s)            |
| $h_i$         | Heat-transfer coefficient at inside tube surface  | $W/(m^2 \cdot K)$            | $\Delta P$          | Pressure drop  | Pa                  |
| $h_o$         | Heat-transfer coefficient at outside tube surface   | $W/(m^2 \cdot K)$            | $\Delta t$          | Temperature difference   | K                   |
| $h_{am}$      | Heat-transfer coefficient for use with $\Delta T_{am}$ ; see Eq. (5-33)   | $W/(m^2 \cdot K)$            | $\Delta T$          | Temperature difference   | K                   |
| $h_{im}$      | Heat-transfer coefficient for use with $\Delta T_{im}$ ; see Eq. (5-32)   | $W/(m^2 \cdot K)$            | $\Delta T_{am}$     | Arithmetic mean temperature difference, see Eq. (5-32)   | K                   |
| $\bar{k}$     | Thermal conductivity  | $W/(m \cdot K)$              | $\Delta T_{lm}$     | Logarithmic mean temperature difference, see Eq. (5-33)  | K                   |
| $k$           | Average thermal conductivity  | $W/(m \cdot K)$              | $\Delta x$          | Thickness of plane wall for conduction   | m                   |
| $L$           | Length of cylinder or length of flat plate in direction of flow or downstream distance. Length of heat-transfer surface | m                            | $\delta_1$          | First dimensionless eigenvalue   |                     |
| $m$           | Fin parameter defined by Eq. (5-75).  |                              | $\delta_{1,0}$      | First dimensionless eigenvalue as Bi approaches 0  |                     |
| $\dot{m}$     | Mass flow rate  | kg/s                         | $\delta_{1,\infty}$ | First dimensionless eigenvalue as Bi approaches $\infty$   |                     |
| $Nu_D$        | Nusselt number based on diameter $D$ , $hD/k$   |                              | $\delta_s$          | Correction factor, ratio of nonnewtonian to newtonian shear rates                                |                     |
| $\bar{Nu}_D$  | Average Nusselt number based on diameter $D$ , $\bar{h}D/k$   |                              | $\epsilon$          | Emissivity of a surface  |                     |
| $Nu_{im}$     | Nusselt number based on $h_{im}$  |                              | $\zeta$             | Dimensionless distance, $r/R$  |                     |
| $n'$          | Flow behavior index for nonnewtonian fluids   |                              | $\theta/\theta_1$   | Dimensionless temperature, $(T - T_\infty)/(T_1 - T_\infty)$                                     |                     |
| $p$           | Perimeter   | m                            | $\lambda$           | Latent heat (enthalpy) of vaporization (condensation)  | J/kg                |
| $p_f$         | Fin perimeter   | m                            | $\mu$               | Viscosity; $\mu_L$ , viscosity of liquid; $\mu_g$ , $\mu_v$ , viscosity of gas or vapor          | kg/(m·s)            |
| $p'$          | Center-to-center spacing of tubes in a bundle   | m                            | $\nu$               | Kinematic viscosity, $\mu/\rho$  | $m^2/s$             |
| $P$           | Absolute pressure; $P_c$ for critical pressure  | kPa                          | $\rho$              | Density; $\rho_L$ , $\rho_f$ for density of liquid; $\rho_G$ , $\rho_v$ for density of vapor     | kg/m <sup>3</sup>   |
| Pr            | Prandtl number, $\nu/\alpha$  |                              | $\sigma$            | Stefan-Boltzmann constant, $5.67 \times 10^{-8}$   | $W/(m^2 \cdot K^4)$ |
| $q$           | Rate of heat transfer   | W                            | $\sigma$            | Surface tension between and liquid and its vapor   | N/m                 |
| $Q$           | Amount of heat transfer   | J                            | $\tau$              | Time constant, time scale  | s                   |
| $\dot{Q}$     | Rate of heat transfer   | W                            | $\Omega$            | Efficiency of fin  |                     |
| $\dot{Q}/Q_i$ | Heat loss fraction, $Q/[\rho c V(T_i - T_\infty)]$  |                              |                     |  |                     |
| $r$           | Distance from center in plate, cylinder, or sphere  | m                            |                     |  |                     |
| $R$           | Thermal resistance or radius  | K/W or m                     |                     |  |                     |

and the average heat thermal conductivity is

$$\bar{k} = k_0(1 + \gamma\bar{T}) \quad (5-6)$$

where  $\bar{T} = 0.5(T_1 + T_2)$ .

For cylinders and spheres,  $A$  is a function of radial position (see Fig. 5-2):  $2\pi rL$  and  $4\pi r^2$ , where  $L$  is the length of the cylinder. For constant  $k$ , Eq. (5-4) becomes

$$\dot{Q} = \frac{T_1 - T_2}{[\ln(r_2/r_1)]/(2\pi kL)} \quad \text{cylinder} \quad (5-7)$$

and

$$\dot{Q} = \frac{T_1 - T_2}{(r_2 - r_1)/(4\pi k r_1 r_2)} \quad \text{sphere} \quad (5-8)$$

**Conduction with Resistances in Series** A steady-state temperature profile in a planar composite wall, with three constant thermal conductivities and no source terms, is shown in Fig. 5-3a. The corresponding thermal circuit is given in Fig. 5-3b. The rate of heat transfer through each of the layers is the same. The total resistance is the sum of the individual resistances shown in Fig. 5-3b:

$$Q = \frac{T_1 - T_2}{\frac{\Delta X_A}{k_A A} + \frac{\Delta X_B}{k_B A} + \frac{\Delta X_C}{k_C A}} = \frac{T_1 - T_2}{R_A + R_B + R_C} \quad (5-9)$$

Additional resistances in the series may occur at the surfaces of the solid if they are in contact with a fluid. The rate of convective heat transfer, between a surface of area  $A$  and a fluid, is represented by Newton's law of cooling as

$$\dot{Q} = hA(T_{\text{surface}} - T_{\text{fluid}}) = \frac{T_{\text{surface}} - T_{\text{fluid}}}{1/(hA)} \quad (5-10)$$

where  $1/(hA)$  is the resistance due to convection (K/W) and the heat-transfer coefficient is  $h$  [W/(m<sup>2</sup>·K)]. For the cylindrical geometry shown in Fig. 5-2, with convection to inner and outer fluids at temperatures  $T_i$  and  $T_o$ , with heat-transfer coefficients  $h_i$  and  $h_o$ , the steady-state rate of heat transfer is

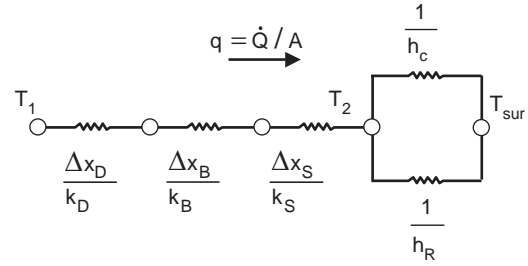

$$\dot{Q} = \frac{T_i - T_o}{\frac{1}{2\pi r_1 L h_i} + \frac{\ln(r_2/r_1)}{2\pi k L} + \frac{1}{2\pi r_2 L h_o}} = \frac{T_i - T_o}{R_i + R_1 + R_o} \quad (5-11)$$

where resistances  $R_i$  and  $R_o$  are the convective resistances at the inner and outer surfaces. The total resistance is again the sum of the resistances in series.

**Example 1: Conduction with Resistances in Series and Parallel** Figure 5-4 shows the thermal circuit for a furnace wall. The outside surface has a known temperature  $T_2 = 625$  K. The temperature of the surroundings

**FIG. 5-3** Steady-state temperature profile in a composite wall with constant thermal conductivities  $k_A$ ,  $k_B$ , and  $k_C$  and no energy sources in the wall. The thermal circuit is shown in (b). The total resistance is the sum of the three resistances shown.

**FIG. 5-4** Thermal circuit for Example 1. Steady-state conduction in a furnace wall with heat losses from the outside surface by convection ( $h_C$ ) and radiation ( $h_R$ ) to the surroundings at temperature  $T_{\text{sur}}$ . The thermal conductivities  $k_D$ ,  $k_B$ , and  $k_S$  are constant, and there are no sources in the wall. The heat flux  $q$  has units of W/m<sup>2</sup>.

$T_{\text{sur}}$  is 290 K. We want to estimate the temperature of the inside wall  $T_1$ . The wall consists of three layers: deposit [ $k_D = 1.6$  W/(m·K),  $\Delta x_D = 0.080$  m], brick [ $k_B = 1.7$  W/(m·K),  $\Delta x_B = 0.15$  m], and steel [ $k_S = 45$  W/(m·K),  $\Delta x_S = 0.00254$  m]. The outside surface loses heat by two parallel mechanisms—convection and radiation. The convective heat-transfer coefficient  $h_C = 5.0$  W/(m<sup>2</sup>·K). The radiative heat-transfer coefficient  $h_R = 16.3$  W/(m<sup>2</sup>·K). The latter is calculated from

$$h_R = \epsilon_2 \sigma (T_2^2 + T_{\text{sur}}^2)(T_2 + T_{\text{sur}}) \quad (5-12)$$

where the emissivity of surface 2 is  $\epsilon_2 = 0.76$  and the Stefan-Boltzmann constant  $\sigma = 5.67 \times 10^{-8}$  W/(m<sup>2</sup>·K<sup>4</sup>).

Referring to Fig. 5-4, the steady-state heat flux  $q$  (W/m<sup>2</sup>) through the wall is

$$q = \frac{\dot{Q}}{A} = \frac{T_1 - T_2}{\frac{\Delta x_D}{k_D} + \frac{\Delta x_B}{k_B} + \frac{\Delta x_S}{k_S}} = (h_C + h_R)(T_2 - T_{\text{sur}})$$

Solving for  $T_1$  gives

$$T_1 = T_2 + \left( \frac{\Delta x_D}{k_D} + \frac{\Delta x_B}{k_B} + \frac{\Delta x_S}{k_S} \right) (h_C + h_R)(T_2 - T_{\text{sur}})$$

and

$$T_1 = 625 + \left( \frac{0.080}{1.6} + \frac{0.15}{1.7} + \frac{0.00254}{45} \right) (5.0 + 16.3)(625 - 290) = 1610 \text{ K}$$

**Conduction with Heat Source** Application of the law of conservation of energy to a one-dimensional solid, with the heat flux given by (5-1) and volumetric source term  $S$  (W/m<sup>3</sup>), results in the following equations for steady-state conduction in a flat plate of thickness  $2R$  ( $b = 1$ ), a cylinder of diameter  $2R$  ( $b = 2$ ), and a sphere of diameter  $2R$  ( $b = 3$ ). The parameter  $b$  is a measure of the curvature. The thermal conductivity is constant, and there is convection at the surface, with heat-transfer coefficient  $h$  and fluid temperature  $T_\infty$ .

$$\frac{d}{dr} \left( r^{b-1} \frac{dT}{dr} \right) + \frac{S}{k} r^{b-1} = 0$$

$$\frac{dT(0)}{dr} = 0 \quad (\text{symmetry condition}) \quad (5-13)$$

$$-k \frac{dT}{dr} = h[T(R) - T_\infty]$$

The solutions to (5-13), for uniform  $S$ , are

$$\frac{T(r) - T_\infty}{SR^2/k} = \frac{1}{2b} \left[ 1 - \left( \frac{r}{R} \right)^2 \right] + \frac{1}{b\text{Bi}} \begin{cases} b = 1, \text{ plate, thickness } 2R \\ b = 2, \text{ cylinder, diameter } 2R \\ b = 3, \text{ sphere, diameter } 2R \end{cases} \quad (5-14)$$

where  $\text{Bi} = hR/k$  is the Biot number. For  $\text{Bi} \ll 1$ , the temperature in the solid is uniform. For  $\text{Bi} \gg 1$ , the surface temperature  $T(R) = T_\infty$ .

**Two- and Three-Dimensional Conduction** Application of the law of conservation of energy to a three-dimensional solid, with the

## 5-6 HEAT AND MASS TRANSFER

heat flux given by (5-1) and volumetric source term  $S$  ( $W/m^3$ ), results in the following equation for steady-state conduction in rectangular coordinates.

$$\frac{\partial}{\partial x} \left( k \frac{\partial T}{\partial x} \right) + \frac{\partial}{\partial y} \left( k \frac{\partial T}{\partial y} \right) + \frac{\partial}{\partial z} \left( k \frac{\partial T}{\partial z} \right) + S = 0 \quad (5-15)$$

Similar equations apply to cylindrical and spherical coordinate systems. Finite difference, finite volume, or finite element methods are generally necessary to solve (5-15). Useful introductions to these numerical techniques are given in the General References and Sec. 3. Simple forms of (5-15) (constant  $k$ , uniform  $S$ ) can be solved analytically. See Arpaci, *Conduction Heat Transfer*, Addison-Wesley, 1966, p. 180, and Carslaw and Jaeger, *Conduction of Heat in Solids*, Oxford University Press, 1959. For problems involving heat flow between two surfaces, each isothermal, with all other surfaces being adiabatic, the shape factor approach is useful (Mills, *Heat Transfer*, 2d ed., Prentice-Hall, 1999, p. 164).

### UNSTEADY-STATE CONDUCTION

Application of the law of conservation of energy to a three-dimensional solid, with the heat flux given by (5-1) and volumetric source term  $S$  ( $W/m^3$ ), results in the following equation for unsteady-state conduction in rectangular coordinates.

$$\rho c \frac{\partial T}{\partial t} = \frac{\partial}{\partial x} \left( k \frac{\partial T}{\partial x} \right) + \frac{\partial}{\partial y} \left( k \frac{\partial T}{\partial y} \right) + \frac{\partial}{\partial z} \left( k \frac{\partial T}{\partial z} \right) + S \quad (5-16)$$

The energy storage term is on the left-hand side, and  $\rho$  and  $c$  are the density ( $kg/m^3$ ) and specific heat [ $J/(kg \cdot K)$ ]. Solutions to (5-16) are generally obtained numerically (see General References and Sec. 3). The one-dimensional form of (5-16), with constant  $k$  and no source term, is

$$\frac{\partial T}{\partial t} = \alpha \frac{\partial^2 T}{\partial x^2} \quad (5-17)$$

where  $\alpha = k/(\rho c)$  is the thermal diffusivity ( $m^2/s$ ).

**One-Dimensional Conduction: Lumped and Distributed Analysis** The one-dimensional transient conduction equations in rectangular ( $b = 1$ ), cylindrical ( $b = 2$ ), and spherical ( $b = 3$ ) coordinates, with constant  $k$ , initial uniform temperature  $T_i$ ,  $S = 0$ , and convection at the surface with heat-transfer coefficient  $h$  and fluid temperature  $T_\infty$ , are

$$\frac{\partial T}{\partial t} = \frac{\alpha}{r^{b-1}} \frac{\partial}{\partial r} \left( r^{b-1} \frac{\partial T}{\partial r} \right) \quad \begin{cases} b = 1, \text{ plate, thickness } 2R \\ b = 2, \text{ cylinder, diameter } 2R \\ b = 3, \text{ sphere, diameter } 2R \end{cases}$$

$$\text{for } t < 0, \quad T = T_i \quad (\text{initial temperature}) \quad (5-18)$$

$$\text{at } r = 0, \quad \frac{\partial T}{\partial r} = 0 \quad (\text{symmetry condition})$$

$$\text{at } r = R, \quad -k \frac{\partial T}{\partial r} = h(T - T_\infty)$$

The solutions to (5-18) can be compactly expressed by using dimensionless variables: (1) temperature  $\theta/\theta_i = [T(r,t) - T_\infty]/(T_i - T_\infty)$ ; (2) heat loss fraction  $Q/Q_i = Q/[\rho c V (T_i - T_\infty)]$ , where  $V$  is volume; (3) distance from center  $\zeta = r/R$ ; (4) time  $Fo = \alpha t/R^2$ , and (5) Biot number  $Bi = hR/k$ . The temperature and heat loss are functions of  $\zeta$ ,  $Fo$ , and  $Bi$ .

When the Biot number is small,  $Bi < 0.2$ , the temperature of the solid is nearly uniform and a lumped analysis is acceptable. The solution to the lumped analysis of (5-18) is

$$\frac{\theta}{\theta_i} = \exp\left(-\frac{hA}{\rho c V} t\right) \quad \text{and} \quad \frac{Q}{Q_i} = 1 - \exp\left(-\frac{hA}{\rho c V} t\right) \quad (5-19)$$

where  $A$  is the active surface area and  $V$  is the volume. The time scale for the lumped problem is

$$\tau = \frac{\rho c V}{hA} \quad (5-20)$$

**TABLE 5-1 Fourier Coefficients and Spatial Functions for Use in Eqs. (5-21)**

| Geometry | $A_1$   | $B_1$  | $S_1$                                     |
|----------|---|--|---|
| Plate    | $\frac{2\sin\delta_1}{\delta_1 + \sin\delta_1\cos\delta_1}$         | $\frac{2Bi^2}{\delta_1^2(Bi^2 + Bi + \delta_1^2)}$ | $\cos(\delta_1\zeta)$                     |
| Cylinder | $\frac{2J_1(\delta_1)}{\delta_1[J_0'(\delta_1) + J_1'(\delta_1)]}$  | $\frac{4Bi^2}{\delta_1^2(\delta_1^2 + Bi^2)}$      | $J_0(\delta_1\zeta)$                      |
| Sphere   | $\frac{2Bi[\delta_1^2 + (Bi - 1)^2]^{1/2}}{\delta_1^2 + Bi^2 - Bi}$ | $\frac{6Bi^2}{\delta_1^2(\delta_1^2 + Bi^2 - Bi)}$ | $\frac{\sin\delta_1\zeta}{\delta_1\zeta}$ |

The time scale is the time required for most of the change in  $\theta/\theta_i$  or  $Q/Q_i$  to occur. When  $t = \tau$ ,  $\theta/\theta_i = \exp(-1) = 0.368$  and roughly two-thirds of the possible change has occurred.

When a lumped analysis is not valid ( $Bi > 0.2$ ), the single-term solutions to (5-18) are convenient:

$$\frac{\theta}{\theta_i} = A_1 \exp(-\delta_1^2 Fo) S_1(\delta_1\zeta) \quad \text{and} \quad \frac{Q}{Q_i} = 1 - B_1 \exp(-\delta_1^2 Fo) \quad (5-21)$$

where the first Fourier coefficients  $A_1$  and  $B_1$  and the spatial functions  $S_1$  are given in Table 5-1. The first eigenvalue  $\delta_1$  is given by (5-22) in conjunction with Table 5-2. The one-term solutions are accurate to within 2 percent when  $Fo > Fo_c$ . The values of the critical Fourier number  $Fo_c$  are given in Table 5-2.

The first eigenvalue is accurately correlated by (Yovanovich, Chap. 3 of Rohsenow, Hartnett, and Cho, *Handbook of Heat Transfer*, 3d ed., McGraw-Hill, 1998, p. 3.25)

$$\delta_1 = \frac{\delta_{1,\infty}}{[1 + (\delta_{1,\infty}/\delta_{1,0})^n]^{1/n}} \quad (5-22)$$

Equation (5-22) gives values of  $\delta_1$  that differ from the exact values by less than 0.4 percent, and it is valid for all values of  $Bi$ . The values of  $\delta_{1,\infty}$ ,  $\delta_{1,0}$ ,  $n$ , and  $Fo_c$  are given in Table 5-2.

**Example 2: Correlation of First Eigenvalues by Eq. (5-22)** As an example of the use of Eq. (5-22), suppose that we want  $\delta_1$  for the flat plate with  $Bi = 5$ . From Table 5-2,  $\delta_{1,\infty} = \pi/2$ ,  $\delta_{1,0} = \sqrt{Bi} = \sqrt{5}$ , and  $n = 2.139$ . Equation (5-22) gives

$$\delta_1 = \frac{\pi/2}{[1 + (\pi/2/\sqrt{5})^{2.139}]^{1/2.139}} = 1.312$$

The tabulated value is 1.3138.

**Example 3: One-Dimensional, Unsteady Conduction Calculation** As an example of the use of Eq. (5-21), Table 5-1, and Table 5-2, consider the cooking time required to raise the center of a spherical, 8-cm-diameter dumpling from 20 to 80°C. The initial temperature is uniform. The dumpling is heated with saturated steam at 95°C. The heat capacity, density, and thermal conductivity are estimated to be  $c = 3500$  J/(kg·K),  $\rho = 1000$  kg/m<sup>3</sup>, and  $k = 0.5$  W/(m·K), respectively.

Because the heat-transfer coefficient for condensing steam is of order  $10^4$ , the  $Bi \rightarrow \infty$  limit in Table 5-2 is a good choice and  $\delta_1 = \pi$ . Because we know the desired temperature at the center, we can calculate  $\theta/\theta_i$  and then solve (5-21) for the time.

$$\frac{\theta}{\theta_i} = \frac{T(0,t) - T_\infty}{T_i - T_\infty} = \frac{80 - 95}{20 - 95} = 0.200$$

For  $Bi \rightarrow \infty$ ,  $A_1$  in Table 5-1 is 2 and for  $\zeta = 0$ ,  $S_1$  in Table 5-1 is 1. Equation (5-21) becomes

$$\frac{\theta}{\theta_i} = 2 \exp(-\pi^2 Fo) = 2 \exp\left(-\frac{\pi^2 \alpha t}{R^2}\right)$$

**TABLE 5-2 First Eigenvalues for  $Bi \rightarrow 0$  and  $Bi \rightarrow \infty$  and Correlation Parameter  $n$**

| Geometry | $Bi \rightarrow 0$                | $Bi \rightarrow \infty$          | $n$   | $Fo_c$ |
|----------|-----------------------------------|----------------------------------|-------|--------|
| Plate    | $\delta_1 \rightarrow \sqrt{Bi}$  | $\delta_1 \rightarrow \pi/2$     | 2.139 | 0.24   |
| Cylinder | $\delta_1 \rightarrow \sqrt{2Bi}$ | $\delta_1 \rightarrow 2.4048255$ | 2.238 | 0.21   |
| Sphere   | $\delta_1 \rightarrow \sqrt{3Bi}$ | $\delta_1 \rightarrow \pi$       | 2.314 | 0.18   |

Solving for  $t$  gives the desired cooking time.

$$t = -\frac{R^2}{\alpha\pi^2} \ln \frac{\theta}{2\theta_1} = -\frac{(0.04 \text{ m})^2}{1.43 \times 10^{-7} (\text{m}^2/\text{s})\pi^2} \ln \frac{0.2}{2} = 43.5 \text{ min}$$

**Example 4: Rule of Thumb for Time Required to Diffuse a Distance  $R$**  A general rule of thumb for estimating the time required to diffuse a distance  $R$  is obtained from the one-term approximations. Consider the equation for the temperature of a flat plate of thickness  $2R$  in the limit as  $\text{Bi} \rightarrow \infty$ . From Table 5-2, the first eigenvalue is  $\delta_1 = \pi/2$ , and from Table 5-1,

$$\frac{\theta}{\theta_1} = A_1 \exp\left[-\left(\frac{\pi}{2}\right)^2 \frac{\alpha t}{R^2}\right] \cos \delta_1 \zeta$$

When  $t = R^2/\alpha$ , the temperature ratio at the center of the plate ( $\zeta = 0$ ) has decayed to  $\exp(-\pi^2/4)$ , or 8 percent of its initial value. We conclude that *diffusion through a distance  $R$  takes roughly  $R^2/\alpha$  units of time, or alternatively, the distance diffused in time  $t$  is about  $(\alpha t)^{1/2}$ .*

**One-Dimensional Conduction: Semi-infinite Plate** Consider a semi-infinite plate with an initial uniform temperature  $T_i$ . Suppose that the temperature of the surface is suddenly raised to  $T_\infty$ ; that is, the heat-transfer coefficient is infinite. The unsteady temperature of the plate is

$$\frac{T(x,t) - T_\infty}{T_i - T_\infty} = \text{erfc}\left(\frac{x}{2\sqrt{\alpha t}}\right) \quad (5-23)$$

where  $\text{erfc}(z)$  is the error function. The depth to which the heat penetrates in time  $t$  is approximately  $(12\alpha t)^{1/2}$ .

If the heat-transfer coefficient is finite,

$$\frac{T(x,t) - T_\infty}{T_i - T_\infty} = \text{erfc}\left(\frac{x}{2\sqrt{\alpha t}}\right) - \exp\left(\frac{hx}{k} + \frac{h^2\alpha t}{k^2}\right) \text{erfc}\left(\frac{x}{2\sqrt{\alpha t}} + \frac{h\sqrt{\alpha t}}{k}\right) \quad (5-24)$$

where  $\text{erfc}(z)$  is the complementary error function. Equations (5-23) and (5-24) are both applicable to finite plates provided that their half-thickness is greater than  $(12\alpha t)^{1/2}$ .

**Two- and Three-Dimensional Conduction** The one-dimensional solutions discussed above can be used to construct solutions to multidimensional problems. The unsteady temperature of a rectangular, solid box of height, length, and width  $2H$ ,  $2L$ , and  $2W$ , respectively, with governing equations in each direction as in (5-18), is

$$\left(\frac{\theta}{\theta_1}\right)_{2H \times 2L \times 2W} = \left(\frac{\theta}{\theta_1}\right)_{2H} \left(\frac{\theta}{\theta_1}\right)_{2L} \left(\frac{\theta}{\theta_1}\right)_{2W} \quad (5-25)$$

Similar products apply for solids with other geometries, e.g., semi-infinite, cylindrical rods.

## HEAT TRANSFER BY CONVECTION

### CONVECTIVE HEAT-TRANSFER COEFFICIENT

Convection is the transfer of energy by conduction and radiation in moving, fluid media. The motion of the fluid is an essential part of convective heat transfer. A key step in calculating the rate of heat transfer by convection is the calculation of the heat-transfer coefficient. This section focuses on the estimation of heat-transfer coefficients for natural and forced convection. The conservation equations for mass, momentum, and energy, as presented in Sec. 6, can be used to calculate the rate of convective heat transfer. Our approach in this section is to rely on correlations.

In many cases of industrial importance, heat is transferred from one fluid, through a solid wall, to another fluid. The transfer occurs in a heat exchanger. Section 11 introduces several types of heat exchangers, design procedures, overall heat-transfer coefficients, and mean temperature differences. Section 3 introduces dimensional analysis and the dimensionless groups associated with the heat-transfer coefficient.

**Individual Heat-Transfer Coefficient** The local rate of convective heat transfer between a surface and a fluid is given by Newton's law of cooling

$$q = h(T_{\text{surface}} - T_{\text{fluid}}) \quad (5-26)$$

where  $h$  [ $\text{W}/(\text{m}^2 \cdot \text{K})$ ] is the local heat-transfer coefficient and  $q$  is the energy flux ( $\text{W}/\text{m}^2$ ). The definition of  $h$  is arbitrary, depending on whether the bulk fluid, centerline, free stream, or some other temperature is used for  $T_{\text{fluid}}$ . The heat-transfer coefficient may be defined on an average basis as noted below.

Consider a fluid with bulk temperature  $T_f$  flowing in a cylindrical tube of diameter  $D$ , with constant wall temperature  $T_s$ . An energy balance on a short section of the tube yields

$$c_p \dot{m} \frac{dT}{dx} = \pi D h (T_s - T) \quad (5-27)$$

where  $c_p$  is the specific heat at constant pressure [ $\text{J}/(\text{kg} \cdot \text{K})$ ],  $\dot{m}$  is the mass flow rate ( $\text{kg}/\text{s}$ ), and  $x$  is the distance from the inlet. If the temperature of the fluid at the inlet is  $T_{\text{in}}$ , the temperature of the fluid at a downstream distance  $L$  is

$$\frac{T(L) - T_s}{T_{\text{in}} - T_s} = \exp\left(-\frac{\bar{h}\pi DL}{\dot{m}c_p}\right) \quad (5-28)$$

The average heat-transfer coefficient  $\bar{h}$  is defined by

$$\bar{h} = \frac{1}{L} \int_0^L h \, dx \quad (5-29)$$

**Overall Heat-Transfer Coefficient and Heat Exchangers** A local, overall heat-transfer coefficient  $U$  for the cylindrical geometry shown in Fig. 5-2 is defined by using Eq. (5-11) as

$$\frac{\dot{Q}}{\Delta x} = \frac{T_i - T_o}{\frac{1}{2\pi r_1 h_i} + \frac{\ln(r_2/r_1)}{2\pi k} + \frac{1}{2\pi r_2 h_o}} = 2\pi r_1 U (T_i - T_o) \quad (5-30)$$

where  $\Delta x$  is a short length of tube in the axial direction. Equation (5-30) defines  $U$  by using the inside perimeter  $2\pi r_1$ . The outer perimeter can also be used. Equation (5-30) applies to clean tubes. Additional resistances are present in the denominator for dirty tubes (see Sec. 11).

For counterflow and parallel flow heat exchanges, with high- and low-temperature fluids ( $T_H$  and  $T_C$ ) and flow directions as defined in Fig. 5-5, the total heat transfer for the exchanger is given by

$$\dot{Q} = UA \Delta T_{\text{lm}} \quad (5-31)$$

where  $A$  is the area for heat exchange and the log mean temperature difference  $\Delta T_{\text{lm}}$  is defined as

$$\Delta T_{\text{lm}} = \frac{(T_H - T_C)_L - (T_H - T_C)_0}{\ln[(T_H - T_C)_L / (T_H - T_C)_0]} \quad (5-32)$$

Equation (5-32) applies to both counterflow and parallel flow exchangers with the nomenclature defined in Fig. 5-5. Correction factors to  $\Delta T_{\text{lm}}$  for various heat exchanger configurations are given in Sec. 11.

In certain applications, the log mean temperature difference is replaced with an arithmetic mean difference:

$$\Delta T_{\text{am}} = \frac{(T_H - T_C)_L + (T_H - T_C)_0}{2} \quad (5-33)$$

Average heat-transfer coefficients are occasionally reported based on Eqs. (5-32) and (5-33) and are written as  $h_{\text{lm}}$  and  $h_{\text{am}}$ .

**Representation of Heat-Transfer Coefficients** Heat-transfer coefficients are usually expressed in two ways: (1) dimensionless relations and (2) dimensional equations. Both approaches are used below. The dimensionless form of the heat-transfer coefficient is the Nusselt

## 5-8 HEAT AND MASS TRANSFER

**FIG. 5-5** Nomenclature for (a) counterflow and (b) parallel flow heat exchangers for use with Eq. (5-32).

number. For example, with a cylinder of diameter  $D$  in cross flow, the local Nusselt number is defined as  $Nu_D = hD/k$ , where  $k$  is the thermal conductivity of the fluid. The subscript  $D$  is important because different characteristic lengths can be used to define  $Nu$ . The average Nusselt number is written  $\overline{Nu}_D = \overline{h}D/k$ .

### NATURAL CONVECTION

Natural convection occurs when a fluid is in contact with a solid surface of different temperature. Temperature differences create the density gradients that drive natural or free convection. In addition to the Nusselt number mentioned above, the key dimensionless parameters for natural convection include the Rayleigh number  $Ra_s = \beta \Delta T g x^3 / \nu \alpha$  and the Prandtl number  $Pr = \nu / \alpha$ . The properties appearing in  $Ra$  and  $Pr$  include the volumetric coefficient of expansion  $\beta$  ( $K^{-1}$ ); the difference  $\Delta T$  between the surface ( $T_s$ ) and free stream ( $T_\infty$ ) temperatures ( $K$  or  $^\circ C$ ); the acceleration of gravity  $g$  ( $m/s^2$ ); a characteristic dimension  $x$  of the surface (m); the kinematic viscosity  $\nu$  ( $m^2/s$ ); and the thermal diffusivity  $\alpha$  ( $m^2/s$ ). The volumetric coefficient of expansion for an ideal gas is  $\beta = 1/T$ , where  $T$  is absolute temperature. For a given geometry,

$$\overline{Nu}_x = f(Ra_x, Pr) \quad (5-34)$$

**External Natural Flow for Various Geometries** For vertical walls, Churchill and Chu [*Int. J. Heat Mass Transfer*, **18**, 1323 (1975)] recommend, for laminar and turbulent flow on isothermal, vertical walls with height  $L$ ,

$$\overline{Nu}_L = \left\{ 0.825 + \frac{0.387 Ra_L^{1/6}}{[1 + (0.492/Pr)^{9/16}]^{8/27}} \right\}^2 \quad (5-35)$$

where the fluid properties for Eq. (5-35) and  $\overline{Nu}_L = \overline{h}L/k$  are evaluated at the film temperature  $T_f = (T_s + T_\infty)/2$ . This correlation is valid for all  $Pr$  and  $Ra_L$ . For vertical cylinders with boundary layer thickness much less than their diameter, Eq. (5-35) is applicable. An expression for uniform heating is available from the same reference.

For laminar and turbulent flow on isothermal, horizontal cylinders of diameter  $D$ , Churchill and Chu [*Int. J. Heat Mass Transfer*, **18**, 1049 (1975)] recommend

$$\overline{Nu}_D = \left\{ 0.60 + \frac{0.387 Ra_D^{1/6}}{[1 + (0.559/Pr)^{9/16}]^{8/27}} \right\}^2 \quad (5-36)$$

Fluid properties for (5-36) should be evaluated at the film temperature  $T_f = (T_s + T_\infty)/2$ . This correlation is valid for all  $Pr$  and  $Ra_D$ .

For horizontal flat surfaces, the characteristic dimension for the correlations is [Goldstein, Sparrow, and Jones, *Int. J. Heat Mass Transfer*, **16**, 1025–1035 (1973)]

$$L = \frac{A}{p} \quad (5-37)$$

where  $A$  is the area of the surface and  $p$  is the perimeter. With hot surfaces facing upward, or cold surfaces facing downward [Lloyd and Moran, ASME Paper 74-WA/HT-66 (1974)],

$$\overline{Nu}_L = \begin{cases} 0.54 Ra_L^{1/4} & 10^4 < Ra_L < 10^7 \\ 0.15 Ra_L^{1/3} & 10^7 < Ra_L < 10^{10} \end{cases} \quad (5-38)$$

and for hot surfaces facing downward, or cold surfaces facing upward,

$$\overline{Nu}_L = 0.27 Ra_L^{1/4} \quad 10^5 < Ra_L < 10^{10} \quad (5-40)$$

Fluid properties for Eqs. (5-38) to (5-40) should be evaluated at the film temperature  $T_f = (T_s + T_\infty)/2$ .

**Simultaneous Heat Transfer by Radiation and Convection** Simultaneous heat transfer by radiation and convection is treated per the procedure outlined in Examples 1 and 5. A radiative heat-transfer coefficient  $h_R$  is defined by (5-12).

**Mixed Forced and Natural Convection** Natural convection is commonly assisted or opposed by forced flow. These situations are discussed, e.g., by Mills (*Heat Transfer*, 2d ed., Prentice-Hall, 1999, p. 340) and Raithby and Hollands (Chap. 4 of Rohsenow, Hartnett, and Cho, *Handbook of Heat Transfer*, 3d ed., McGraw-Hill, 1998, p. 4.73).

**Enclosed Spaces** The rate of heat transfer across an enclosed space is described in terms of a heat-transfer coefficient based on the temperature difference between two surfaces:

$$\overline{h} = \frac{\dot{Q}/A}{T_H - T_C} \quad (5-41)$$

For rectangular cavities, the plate spacing between the two surfaces  $L$  is the characteristic dimension that defines the Nusselt and Rayleigh numbers. The temperature difference in the Rayleigh number,  $Ra_L = \beta \Delta T g L^3 / \nu \alpha$  is  $\Delta T = T_H - T_C$ .

For a horizontal rectangular cavity heated from below, the onset of advection requires  $Ra_L > 1708$ . Globe and Dropkin [*J. Heat Transfer*, **81**, 24–28 (1959)] propose the correlation

$$\overline{Nu}_L = 0.069 Ra_L^{1/3} Pr^{0.074} \quad 3 \times 10^5 < Ra_L < 7 \times 10^9 \quad (5-42)$$

All properties in (5-42) are calculated at the average temperature  $(T_H + T_C)/2$ .

For vertical rectangular cavities of height  $H$  and spacing  $L$ , with  $Pr \approx 0.7$  (gases) and  $40 < H/L < 110$ , the equation of Shewen et al. [*J. Heat Transfer*, **118**, 993–995 (1996)] is recommended:

$$\overline{Nu}_L = \left\{ 1 + \left[ \frac{0.0665 Ra_L^{1/3}}{1 + (9000/Ra_L)^{1.4}} \right]^2 \right\}^{1/2} \quad Ra_L < 10^6 \quad (5-43)$$

All properties in (5-43) are calculated at the average temperature  $(T_H + T_C)/2$ .

#### Example 5: Comparison of the Relative Importance of Natural Convection and Radiation at Room Temperature

Estimate the heat losses by natural convection and radiation for an undraped person standing in still air. The temperatures of the air, surrounding surfaces, and skin are 19, 15, and 35 $^\circ C$ , respectively. The height and surface area of the person are 1.8 m and 1.8 m $^2$ . The emissivity of the skin is 0.95.

We can estimate the Nusselt number by using (5-35) for a vertical, flat plate of height  $L = 1.8$  m. The film temperature is  $(19 + 35)/2 = 27^\circ C$ . The Rayleigh number, evaluated at the film temperature, is

$$Ra_L = \frac{\beta \Delta T g L^3}{\nu \alpha} = \frac{(1/300)(35 - 19)9.81(1.8)^3}{1.589 \times 10^{-5}(2.25 \times 10^{-5})} = 8.53 \times 10^9$$

From (5-35) with  $Pr = 0.707$ , the Nusselt number is 240 and the average heat-transfer coefficient due to natural convection is

$$\overline{h} = \frac{k}{L} \overline{Nu}_L = \frac{0.0263}{1.8} (240) = 3.50 \frac{W}{m^2 \cdot K}$$

The radiative heat-transfer coefficient is given by (5-12):

$$h_R = \epsilon_{\text{skin}} \sigma (T_{\text{skin}}^2 + T_{\text{sur}}^2)(T_{\text{skin}} + T_{\text{sur}}) \\ = 0.95(5.67 \times 10^{-8})(308^2 + 288^2)(308 + 288) = 5.71 \frac{\text{W}}{\text{m}^2 \cdot \text{K}}$$

The total rate of heat loss is

$$\dot{Q} = \bar{h}A(T_{\text{skin}} - T_{\text{sur}}) + \bar{h}_R A(T_{\text{skin}} - T_{\text{sur}}) \\ = 3.50(1.8)(35 - 19) + 5.71(1.8)(35 - 15) = 306 \text{ W}$$

At these conditions, radiation is nearly twice as important as natural convection.

## FORCED CONVECTION

Forced convection heat transfer is probably the most common mode in the process industries. Forced flows may be internal or external. This subsection briefly introduces correlations for estimating heat-transfer coefficients for flows in tubes and ducts; flows across plates, cylinders, and spheres; flows through tube banks and packed beds; heat transfer to nonevaporating falling films; and rotating surfaces. Section 11 introduces several types of heat exchangers, design procedures, overall heat-transfer coefficients, and mean temperature differences.

**Flow in Round Tubes** In addition to the Nusselt ( $\text{Nu}_D = hD/k$ ) and Prandtl ( $\text{Pr} = \nu/\alpha$ ) numbers introduced above, the key dimensionless parameter for forced convection in round tubes of diameter  $D$  is the Reynolds number  $\text{Re} = GD/\mu$ , where  $G$  is the mass velocity  $G = \dot{m}/A_c$  and  $A_c$  is the cross-sectional area  $A_c = \pi D^2/4$ . For internal flow in a tube or duct, the heat-transfer coefficient is defined as

$$q = h(T_b - T_s) \quad (5-44)$$

where  $T_b$  is the bulk or mean temperature at a given cross section and  $T_s$  is the corresponding surface temperature.

For laminar flow ( $\text{Re}_D < 2100$ ) that is fully developed, both hydrodynamically and thermally, the Nusselt number has a constant value. For a uniform wall temperature,  $\text{Nu}_D = 3.66$ . For a uniform heat flux through the tube wall,  $\text{Nu}_D = 4.36$ . In both cases, the thermal conductivity of the fluid in  $\text{Nu}_D$  is evaluated at  $T_b$ . The distance  $x$  required for a fully developed laminar velocity profile is given by  $[(x/D)/\text{Re}_D] \approx 0.05$ . The distance  $x$  required for fully developed velocity and thermal profiles is obtained from  $[(x/D)/(\text{Re}_D \text{Pr})] \approx 0.05$ .

For a constant wall temperature, a fully developed laminar velocity profile, and a developing thermal profile, the average Nusselt number is estimated by [Hausen, *Allg. Waermetech.*, **9**, 75 (1959)]

$$\bar{\text{Nu}}_D = 3.66 + \frac{0.0668(D/L) \text{Re}_D \text{Pr}}{1 + 0.04[(D/L) \text{Re}_D \text{Pr}]^{2/3}} \quad (5-45)$$

For large values of  $L$ , Eq. (5-45) approaches  $\text{Nu}_D = 3.66$ . Equation (5-45) also applies to developing velocity and thermal profiles conditions if  $\text{Pr} \gg 1$ . The properties in (5-45) are evaluated at the bulk mean temperature

$$\bar{T}_b = (T_{b,\text{in}} + T_{b,\text{out}})/2 \quad (5-46)$$

For a constant wall temperature with developing laminar velocity and thermal profiles, the average Nusselt number is approximated by [Sieder and Tate, *Ind. Eng. Chem.*, **28**, 1429 (1936)]

$$\bar{\text{Nu}}_D = 1.86 \left( \frac{D}{L} \text{Re}_D \text{Pr} \right)^{1/3} \left( \frac{\mu_b}{\mu_s} \right)^{0.14} \quad (5-47)$$

The properties, except for  $\mu_s$ , are evaluated at the bulk mean temperature per (5-46) and  $0.48 < \text{Pr} < 16,700$  and  $0.0044 < \mu_b/\mu_s < 9.75$ .

For fully developed flow in the transition region between laminar and turbulent flow, and for fully developed turbulent flow, Gnielinski's [Int. Chem. Eng., **16**, 359 (1976)] equation is recommended:

$$\text{Nu}_D = \frac{(f/2)(\text{Re}_D - 1000)(\text{Pr})}{1 + 12.7(f/2)^{1/2}(\text{Pr}^{2/3} - 1)} K \quad (5-48)$$

where  $0.5 < \text{Pr} < 10^5$ ,  $2300 < \text{Re}_D < 10^6$ ,  $K = (\text{Pr}_b/\text{Pr}_s)^{0.11}$  for liquids ( $0.05 < \text{Pr}_b/\text{Pr}_s < 20$ ), and  $K = (T_b/T_s)^{0.45}$  for gases ( $0.5 < T_b/T_s < 1.5$ ). The factor  $K$  corrects for variable property effects. For smooth tubes, the Fanning friction factor  $f$  is given by

$$f = 0.25(0.790 \ln \text{Re}_D - 1.64)^{-2} \quad 2300 < \text{Re}_D < 10^6 \quad (5-49)$$

**TABLE 5-3 Effect of Entrance Configuration on Values of  $C$  and  $n$  in Eq. (5-53) for  $\text{Pr} \approx 1$  (Gases and Other Fluids with  $\text{Pr}$  about 1)**

| Entrance configuration | $C$    | $n$   |
|------------------------|--------|-------|
| Long calming section   | 0.9756 | 0.760 |
| Open end, 90° edge     | 2.4254 | 0.676 |
| 180° return bend       | 0.9759 | 0.700 |
| 90° round bend         | 1.0517 | 0.629 |
| 90° elbow              | 2.0152 | 0.614 |

For rough pipes, approximate values of  $\text{Nu}_D$  are obtained if  $f$  is estimated by the Moody diagram of Sec. 6. Equation (5-48) is corrected for entrance effects per (5-53) and Table 5-3. Sieder and Tate [Ind. Eng. Chem., **28**, 1429 (1936)] recommend a simpler but less accurate equation for fully developed turbulent flow

$$\text{Nu}_D = 0.027 \text{Re}_D^{4/5} \text{Pr}^{1/3} \left( \frac{\mu_b}{\mu_s} \right)^{0.14} \quad (5-50)$$

where  $0.7 < \text{Pr} < 16,700$ ,  $\text{Re}_D < 10,000$ , and  $L/D > 10$ . Equations (5-48) and (5-50) apply to both constant temperature and uniform heat flux along the tube. The properties are evaluated at the bulk temperature  $T_b$ , except for  $\mu_s$ , which is at the temperature of the tube. For  $L/D$  greater than about 10, Eqs. (5-48) and (5-50) provide an estimate of  $\text{Nu}_D$ . In this case, the properties are evaluated at the bulk mean temperature per (5-46). More complicated and comprehensive predictions of fully developed turbulent convection are available in Churchill and Žajic [AIChE J., **48**, 927 (2002)] and Yu, Ozoe, and Churchill [Chem. Eng. Science, **56**, 1781 (2001)].

For fully developed turbulent flow of liquid metals, the Nusselt number depends on the wall boundary condition. For a constant wall temperature [Notter and Sleicher, Chem. Eng. Science, **27**, 2073 (1972)],

$$\text{Nu}_D = 4.8 + 0.0156 \text{Re}_D^{0.85} \text{Pr}^{0.93} \quad (5-51)$$

while for a uniform wall heat flux,

$$\text{Nu}_D = 6.3 + 0.0167 \text{Re}_D^{0.85} \text{Pr}^{0.93} \quad (5-52)$$

In both cases the properties are evaluated at  $T_b$  and  $0.004 < \text{Pr} < 0.01$  and  $10^4 < \text{Re}_D < 10^6$ .

Entrance effects for turbulent flow with simultaneously developing velocity and thermal profiles can be significant when  $L/D < 10$ . Shah and Bhatti correlated entrance effects for gases ( $\text{Pr} \approx 1$ ) to give an equation for the average Nusselt number in the entrance region (in Kaka, Shah, and Aung, eds., *Handbook of Single-Phase Convective Heat Transfer*, Chap. 3, Wiley-Interscience, 1987).

$$\frac{\bar{\text{Nu}}_D}{\text{Nu}_D} = 1 + \frac{C}{(x/D)^n} \quad (5-53)$$

where  $\text{Nu}_D$  is the fully developed Nusselt number and the constants  $C$  and  $n$  are given in Table 5-3 (Ebadian and Dong, Chap. 5 of Rohsenow, Hartnett, and Cho, *Handbook of Heat Transfer*, 3d ed., McGraw-Hill, 1998, p. 5.31). The tube entrance configuration determines the values of  $C$  and  $n$  as shown in Table 5-3.

**Flow in Noncircular Ducts** The length scale in the Nusselt and Reynolds numbers for noncircular ducts is the hydraulic diameter,  $D_h = 4A_c/p$ , where  $A_c$  is the cross-sectional area for flow and  $p$  is the wetted perimeter. Nusselt numbers for fully developed laminar flow in a variety of noncircular ducts are given by Mills (*Heat Transfer*, 2d ed., Prentice-Hall, 1999, p. 307). For turbulent flows, correlations for round tubes can be used with  $D$  replaced by  $D_h$ .

For annular ducts, the accuracy of the Nusselt number given by (5-48) is improved by the following multiplicative factors [Petukhov and Roizen, *High Temp.*, **2**, 65 (1964)].

$$\text{Inner tube heated} \quad 0.86 \left( \frac{D_i}{D_o} \right)^{-0.16}$$

$$\text{Outer tube heated} \quad 1 - 0.14 \left( \frac{D_i}{D_o} \right)^{0.6}$$

where  $D_i$  and  $D_o$  are the inner and outer diameters, respectively.

**Example 6: Turbulent Internal Flow** Air at 300 K, 1 bar, and 0.05 kg/s enters a channel of a plate-type heat exchanger (Mills, *Heat Transfer*, 2d ed., Prentice-Hall, 1999) that measures 1 cm wide, 0.5 m high, and 0.8 m long. The walls are at 600 K, and the mass flow rate is 0.05 kg/s. The entrance has a 90° edge. We want to estimate the exit temperature of the air.

Our approach will use (5-48) to estimate the average heat-transfer coefficient, followed by application of (5-28) to calculate the exit temperature. We assume ideal gas behavior and an exit temperature of 500 K. The estimated bulk mean temperature of the air is, by (5-46), 400 K. At this temperature, the properties of the air are  $Pr = 0.690$ ,  $\mu = 2.301 \times 10^{-5}$  kg/(m·s),  $k = 0.0338$  W/(m·K), and  $c_p = 1014$  J/(kg·K).

We start by calculating the hydraulic diameter  $D_h = 4A_c/p$ . The cross-sectional area for flow  $A_c$  is  $0.005$  m<sup>2</sup>, and the wetted perimeter  $p$  is  $1.02$  m. The hydraulic diameter  $D_h = 0.01961$  m. The Reynolds number is

$$Re_D = \frac{\dot{m} D_h}{A_c \mu} = \frac{0.05(0.01961)}{0.005(2.301 \times 10^{-5})} = 8521$$

The flow is in the transition region, and Eqs. (5-49) and (5-48) apply:

$$f = 0.25(0.790 \ln Re_D - 1.64)^{-2} = 0.25(0.790 \ln 8521 - 1.64)^{-2} = 0.008235$$

$$Nu_D = \frac{(f/2)(Re_D - 1000)(Pr)}{1 + 12.7(f/2)^{1/2}(Pr^{2/3} - 1)} K$$

$$= \frac{(0.008235/2)(8521 - 1000)(0.690)}{1 + 12.7(0.008235/2)^{1/2}(0.690^{2/3} - 1)} \left(\frac{400}{600}\right)^{0.45} = 21.68$$

Entrance effects are included by using (5-53) for an open end, 90° edge:

$$\overline{Nu}_D = \left[1 + \frac{C}{(x/D)^n}\right] Nu_D = \left[1 + \frac{2.4254}{(0.8/0.01961)^{0.676}}\right] (21.68) = 25.96$$

The average heat-transfer coefficient becomes

$$\bar{h} = \frac{k}{D_h} \overline{Nu}_D = \frac{0.0338}{0.01961} (25.96) = 44.75 \frac{W}{m^2 \cdot K}$$

The exit temperature is calculated from (5-28):

$$T(L) = T_s - (T_s - T_m) \exp\left(-\frac{\bar{h} p L}{\dot{m} c_p}\right)$$

$$= 600 - (600 - 300) \exp\left[-\frac{44.75(1.02)0.8}{0.05(1014)}\right] = 450 \text{ K}$$

We conclude that our estimated exit temperature of 500 K is too high. We could repeat the calculations, using fluid properties evaluated at a revised bulk mean temperature of 375 K.

**Coiled Tubes** For turbulent flow inside helical coils, with tube inside radius  $a$  and coil radius  $R$ , the Nusselt number for a straight tube  $Nu_s$  is related to that for a coiled tube  $Nu_c$ , by (Rohsenow, Hartnett, and Cho, *Handbook of Heat Transfer*, 3d ed., McGraw-Hill, 1998, p. 5.90)

$$\frac{Nu_c}{Nu_s} = 1.0 + 3.6 \left(1 - \frac{a}{R}\right) \left(\frac{a}{R}\right)^{0.5} \quad (5-54)$$

where  $2 \times 10^4 < Re_D < 1.5 \times 10^5$  and  $5 < R/a < 84$ . For lower Reynolds numbers ( $1.5 \times 10^3 < Re_D < 2 \times 10^4$ ), the same source recommends

$$\frac{Nu_c}{Nu_s} = 1.0 + 3.4 \frac{a}{R} \quad (5-55)$$

**External Flows** For a single cylinder in cross flow, Churchill and Bernstein recommend [*J. Heat Transfer*, **99**, 300 (1977)]

$$\overline{Nu}_D = 0.3 + \frac{0.62 Re_D^{1/2} Pr^{1/3}}{[1 + (0.4/Pr)^{2/3}]^{1/4}} \left[1 + \left(\frac{Re_D}{282,000}\right)^{5/8}\right]^{4/5} \quad (5-56)$$

where  $\overline{Nu}_D = \bar{h}D/k$ . Equation (5-56) is for all values of  $Re_D$  and  $Pr$ , provided that  $Re_D Pr > 0.4$ . The fluid properties are evaluated at the film temperature  $(T_e + T_s)/2$ , where  $T_e$  is the free-stream temperature and  $T_s$  is the surface temperature. Equation (5-56) also applies to the uniform heat flux boundary condition provided  $\bar{h}$  is based on the perimeter-averaged temperature difference between  $T_s$  and  $T_e$ .

For an isothermal spherical surface, Whitaker recommends [*AIChE*, **18**, 361 (1972)]

$$\overline{Nu}_D = 2 + (0.4 Re_D^{1/2} + 0.06 Re_D^{2/3}) Pr^{0.4} \left(\frac{\mu_e}{\mu_s}\right)^{1/4} \quad (5-57)$$

This equation is based on data for  $0.7 < Pr < 380$ ,  $3.5 < Re_D < 8 \times 10^4$ , and  $1 < (\mu_e/\mu_s) < 3.2$ . The properties are evaluated at the free-stream temperature  $T_e$ , with the exception of  $\mu_s$ , which is evaluated at the surface temperature  $T_s$ .

The average Nusselt number for laminar flow over an isothermal flat plate of length  $x$  is estimated from [Churchill and Ozoe, *J. Heat Transfer*, **95**, 416 (1973)]

$$\overline{Nu}_x = \frac{1.128 Pr^{1/2} Re_x^{1/2}}{[1 + (0.0468/Pr)^{2/3}]^{1/4}} \quad (5-58)$$

This equation is valid for all values of  $Pr$  as long as  $Re_x Pr > 100$  and  $Re_x < 5 \times 10^5$ . The fluid properties are evaluated at the film temperature  $(T_e + T_s)/2$ , where  $T_e$  is the free-stream temperature and  $T_s$  is the surface temperature. For a uniformly heated flat plate, the local Nusselt number is given by [Churchill and Ozoe, *J. Heat Transfer*, **95**, 78 (1973)]

$$Nu_x = \frac{0.886 Pr^{1/2} Re_x^{1/2}}{[1 + (0.0207/Pr)^{2/3}]^{1/4}} \quad (5-59)$$

where again the properties are evaluated at the film temperature.

The average Nusselt number for turbulent flow over a smooth, isothermal flat plate of length  $x$  is given by (Mills, *Heat Transfer*, 2d ed., Prentice-Hall, 1999, p. 315)

$$\overline{Nu}_x = 0.664 Re_{cr}^{1/2} Pr^{1/3} + 0.036 Re_x^{0.8} Pr^{0.43} \left[1 - \left(\frac{Re_{cr}}{Re_x}\right)^{0.5}\right] \quad (5-60)$$

The critical Reynolds number  $Re_{cr}$  is typically taken as  $5 \times 10^5$ ,  $Re_{cr} < Re_x < 3 \times 10^7$ , and  $0.7 < Pr < 400$ . The fluid properties are evaluated at the film temperature  $(T_e + T_s)/2$ , where  $T_e$  is the free-stream temperature and  $T_s$  is the surface temperature. Equation (5-60) also applies to the uniform heat flux boundary condition provided  $\bar{h}$  is based on the average temperature difference between  $T_s$  and  $T_e$ .

**Flow-through Tube Banks** Aligned and staggered tube banks are sketched in Fig. 5-6. The tube diameter is  $D$ , and the transverse and longitudinal pitches are  $S_T$  and  $S_L$ , respectively. The fluid velocity upstream of the tubes is  $V_\infty$ .

FIG. 5-6 (a) Aligned and (b) staggered tube bank configurations. The fluid velocity upstream of the tubes is  $V_\infty$ .

of the tubes is  $V_\infty$ . To estimate the overall heat-transfer coefficient for the tube bank, Mills proceeds as follows (*Heat Transfer*, 2d ed., Prentice-Hall, 1999, p. 348). The Reynolds number for use in (5-56) is recalculated with an effective average velocity in the space between adjacent tubes:

$$\frac{\bar{V}}{V_\infty} = \frac{S_T}{S_T - (\pi/4)D} \quad (5-61)$$

The heat-transfer coefficient increases from row 1 to about row 5 of the tube bank. The average Nusselt number for a tube bank with 10 or more rows is

$$\overline{Nu}_D^{10+} = \Phi \overline{Nu}_D \quad (5-62)$$

where  $\Phi$  is an arrangement factor and  $\overline{Nu}_D$  is the Nusselt number for the first row, calculated by using the velocity in (5-61). The arrangement factor is calculated as follows. Define dimensionless pitches as  $P_T = S_T/D$  and  $P_L/D$  and calculate a factor  $\psi$  as follows.

$$\psi = \begin{cases} 1 - \frac{\pi}{4P_T} & \text{if } P_L \geq 1 \\ 1 - \frac{\pi}{4P_T P_L} & \text{if } P_L < 1 \end{cases} \quad (5-63)$$

The arrangement factors are

$$\Phi_{\text{aligned}} = 1 + \frac{0.7}{\psi^{1.5}} \frac{S_T/S_T - 0.3}{(S_T/S_T + 0.7)^2} \quad (5-64)$$

$$\Phi_{\text{staggered}} = 1 + \frac{2}{3P_L} \quad (5-65)$$

If there are fewer than 10 rows,

$$\overline{Nu}_D = \frac{1 + (N-1)\Phi}{N} \overline{Nu}_D \quad (5-66)$$

where  $N$  is the number of rows.

The fluid properties for gases are evaluated at the average mean film temperature  $[(T_{in} + T_{out})/2 + T_s]/2$ . For liquids, properties are evaluated at the bulk mean temperature  $(T_{in} + T_{out})/2$ , with a Prandtl number correction  $(Pr_f/Pr_s)^{0.11}$  for cooling and  $(Pr_f/Pr_s)^{0.25}$  for heating.

**Falling Films** When a liquid is distributed uniformly around the periphery at the top of a vertical tube (either inside or outside) and allowed to fall down the tube wall by the influence of gravity, the fluid does not fill the tube but rather flows as a thin layer. Similarly, when a liquid is applied uniformly to the outside and top of a horizontal tube, it flows in layer form around the periphery and falls off the bottom. In both these cases the mechanism is called gravity flow of liquid layers or falling films.

For the turbulent flow of **water** in layer form down the walls of **vertical tubes** the dimensional equation of McAdams, Drew, and Bays [*Trans. Am. Soc. Mech. Eng.*, **62**, 627 (1940)] is recommended:

$$h_{lm} = b\Gamma^{1/3} \quad (5-67)$$

where  $b = 9150$  (SI) or 120 (U.S. Customary) and is based on values of  $\Gamma = W_F = \dot{M}/\pi D$  ranging from 0.25 to 6.2 kg/(m·s) [600 to 15,000 lb/(h·ft)] of wetted perimeter. This type of water flow is used in vertical vapor-in-shell ammonia condensers, acid coolers, cycle water coolers, and other process-fluid coolers.

The following dimensional equations may be used for **any liquid** flowing in layer form down **vertical surfaces**:

$$\text{For } \frac{4\Gamma}{\mu} > 2100 \quad h_{lm} = 0.01 \left( \frac{k^3 \rho^2 g}{\mu^2} \right)^{1/3} \left( \frac{c\mu}{k} \right)^{1/3} \left( \frac{4\Gamma}{\mu} \right)^{1/3} \quad (5-68a)$$

$$\text{For } \frac{4\Gamma}{\mu} < 2100 \quad h_{am} = 0.50 \left( \frac{k^3 \rho^{4/3} c g^{2/3}}{L\mu^{1/3}} \right)^{1/3} \left( \frac{\mu}{\mu_w} \right)^{1/4} \left( \frac{4\Gamma}{\mu} \right)^{1/9} \quad (5-68b)$$

Equation (5-68b) is based on the work of Bays and McAdams [*Ind. Eng. Chem.*, **29**, 1240 (1937)]. The significance of the term  $L$  is not clear. When  $L = 0$ , the coefficient is definitely not infinite. When  $L$  is large and the fluid temperature has not yet closely approached the wall temperature, it does not appear that the coefficient should

necessarily decrease. Within the finite limits of 0.12 to 1.8 m (0.4 to 6 ft), this equation should give results of the proper order of magnitude.

For falling films applied to the **outside of horizontal tubes**, the Reynolds number rarely exceeds 2100. Equations may be used for falling films on the outside of the tubes by substituting  $\pi D/2$  for  $L$ .

For **water** flowing over a **horizontal tube**, data for several sizes of pipe are roughly correlated by the dimensional equation of McAdams, Drew, and Bays [*Trans. Am. Soc. Mech. Eng.*, **62**, 627 (1940)].

$$h_{am} = b(\Gamma/D_0)^{1/3} \quad (5-69)$$

where  $b = 3360$  (SI) or 65.6 (U.S. Customary) and  $\Gamma$  ranges from 0.94 to 4 kg/(m·s) [100 to 1000 lb/(h·ft)].

Falling films are also used for evaporation in which the film is both entirely or partially evaporated (juice concentration). This principle is also used in crystallization (freezing).

The advantage of high coefficient in falling-film exchangers is partially offset by the difficulties involved in distribution of the film, maintaining complete wettability of the tube, and pumping costs required to lift the liquid to the top of the exchanger.

**Finned Tubes (Extended Surface)** When the heat-transfer coefficient on the outside of a metal tube is much lower than that on the inside, as when steam condensing in a pipe is being used to heat air, externally finned (or extended) heating surfaces are of value in increasing substantially the rate of heat transfer per unit length of tube. The data on extended heating surfaces, for the case of air flowing outside and at right angles to the axes of a bank of finned pipes, can be represented approximately by the dimensional equation derived from

$$h_f = b \frac{V_F^{0.6}}{D_0^{0.4}} \left( \frac{p'}{p' - D_0} \right)^{0.6} \quad (5-70)$$

where  $b = 5.29$  (SI) or (5.39)(10<sup>-3</sup>) (U.S. Customary);  $h_f$  is the coefficient of heat transfer on the air side;  $V_F$  is the face velocity of the air;  $p'$  is the center-to-center spacing, m, of the tubes in a row; and  $D_0$  is the outside diameter, m, of the bare tube (diameter at the root of the fins).

In atmospheric air-cooled finned tube exchangers, the air-film coefficient from Eq. (5-70) is sometimes converted to a value based on outside bare surface as follows:

$$h_{fo} = h_f \frac{A_f + A_{uf}}{A_{of}} = h_f \frac{A_T}{A_o} \quad (5-71)$$

in which  $h_{fo}$  is the air-film coefficient based on external bare surface;  $h_f$  is the air-film coefficient based on total external surface;  $A_T$  is total external surface, and  $A_o$  is external bare surface of the unfinned tube;  $A_f$  is the area of the fins;  $A_{uf}$  is the external area of the unfinned portion of the tube; and  $A_{of}$  is area of tube before fins are attached.

**Fin efficiency** is defined as the ratio of the mean temperature difference from surface to fluid divided by the temperature difference from fin to fluid at the base or root of the fin. Graphs of fin efficiency for extended surfaces of various types are given by Gardner [*Trans. Am. Soc. Mech. Eng.*, **67**, 621 (1945)].

Heat-transfer coefficients for finned tubes of various types are given in a series of papers [*Trans. Am. Soc. Mech. Eng.*, **67**, 601 (1945)].

For flow of air normal to fins in the form of **short strips or pins**, Norris and Spofford [*Trans. Am. Soc. Mech. Eng.*, **64**, 489 (1942)] correlate their results for air by the dimensionless equation of Pohlhausen:

$$\frac{h_m}{c_p G_{\max}} \left( \frac{c_p \mu}{k} \right)^{2/3} = 1.0 \left( \frac{z_p G_{\max}}{\mu} \right)^{-0.5} \quad (5-72)$$

for values of  $z_p G_{\max}/\mu$  ranging from 2700 to 10,000.

For the general case, the treatment suggested by Kern (*Process Heat Transfer*, McGraw-Hill, New York, 1950, p. 512) is recommended. Because of the wide variations in fin-tube construction, it is convenient to convert all coefficients to values based on the inside bare surface of the tube. Thus to convert the coefficient based on outside area (finned side) to a value based on inside area Kern gives the following relationship:

$$h_{fi} = (\Omega A_f + A_o)(h_f/A_o) \quad (5-73)$$

## 5-12 HEAT AND MASS TRANSFER

in which  $h_f$  is the effective outside coefficient based on the inside area,  $h_f$  is the outside coefficient calculated from the applicable equation for bare tubes,  $A_f$  is the surface area of the fins,  $A_o$  is the surface area on the outside of the tube which is not finned,  $A_i$  is the inside area of the tube, and  $\Omega$  is the fin efficiency defined as

$$\Omega = (\tanh mb_f)/mb_f \quad (5-74)$$

in which

$$m = (h_f p_f / ka_f)^{1/2} \quad \text{m}^{-1} \text{ (ft}^{-1}\text{)} \quad (5-75)$$

and  $b_f$  = height of fin. The other symbols are defined as follows:  $p_f$  is the perimeter of the fin,  $a_f$  is the cross-sectional area of the fin, and  $k$  is the thermal conductivity of the material from which the fin is made.

Fin efficiencies and fin dimensions are available from manufacturers. Ratios of finned to inside surface are usually available so that the terms  $A_f$ ,  $A_o$ , and  $A_i$  may be obtained from these ratios rather than from the total surface areas of the heat exchangers.

### JACKETS AND COILS OF AGITATED VESSELS

See Secs. 11 and 18.

### NONNEWTONIAN FLUIDS

A wide variety of nonnewtonian fluids are encountered industrially. They may exhibit Bingham-plastic, pseudoplastic, or dilatant behavior

and may or may not be thixotropic. For design of equipment to handle or process nonnewtonian fluids, the properties must usually be measured experimentally, since no generalized relationships exist to predict the properties or behavior of the fluids. Details of handling nonnewtonian fluids are described completely by Skelland (*Non-Newtonian Flow and Heat Transfer*, Wiley, New York, 1967). The generalized shear-stress rate-of-strain relationship for nonnewtonian fluids is given as

$$n' = \frac{d \ln (D \Delta P / 4L)}{d \ln (8V/D)} \quad (5-76)$$

as determined from a plot of shear stress versus velocity gradient.

For **circular tubes**,  $Gz > 100$ ,  $n' > 0.1$ , and laminar flow

$$Nu_m = 1.75 \delta_s^{1/3} Gz^{1/3} \quad (5-77)$$

where  $\delta_s = (3n' + 1)/4n'$ . When natural convection effects are considered, Metzner and Gluck [*Chem. Eng. Sci.*, **12**, 185 (1960)] obtained the following for **horizontal tubes**:

$$Nu_m = 1.75 \delta_s^{1/3} \left[ Gz + 12.6 \left( \frac{\text{Pr Gr} D}{L} \right)^{0.4} \right]^{1/3} \left( \frac{\gamma_b}{\gamma_w} \right)^{0.14} \quad (5-78)$$

where properties are evaluated at the wall temperature, i.e.,  $\gamma = g_r K' 8^{n'-3}$  and  $\tau_w = K' (8V/D)^{n'}$ .

Metzner and Friend [*Ind. Eng. Chem.*, **51**, 879 (1959)] present relationships for turbulent heat transfer with nonnewtonian fluids. Relationships for heat transfer by natural convection and through laminar boundary layers are available in Skelland's book (op. cit.).

## HEAT TRANSFER WITH CHANGE OF PHASE

In any operation in which a material undergoes a change of phase, provision must be made for the addition or removal of heat to provide for the latent heat of the change of phase plus any other sensible heating or cooling that occurs in the process. Heat may be transferred by any one or a combination of the three modes—conduction, convection, and radiation. The process involving change of phase involves mass transfer simultaneous with heat transfer.

### CONDENSATION

**Condensation Mechanisms** Condensation occurs when a saturated vapor comes in contact with a surface whose temperature is below the saturation temperature. Normally a film of condensate is formed on the surface, and the thickness of this film, per unit of breadth, increases with increase in extent of the surface. This is called **film-type condensation**.

Another type of condensation, called **dropwise**, occurs when the wall is not uniformly wetted by the condensate, with the result that the condensate appears in many small droplets at various points on the surface. There is a growth of individual droplets, a coalescence of adjacent droplets, and finally a formation of a rivulet. Adhesive force is overcome by gravitational force, and the rivulet flows quickly to the bottom of the surface, capturing and absorbing all droplets in its path and leaving dry surface in its wake.

Film-type condensation is more common and more dependable. Dropwise condensation normally needs to be promoted by introducing an impurity into the vapor stream. Substantially higher (6 to 18 times) coefficients are obtained for dropwise condensation of steam, but design methods are not available. Therefore, the development of equations for condensation will be for the film type only.

The physical properties of the liquid, rather than those of the vapor, are used for determining the coefficient for condensation. Nusselt [*Z. Ver. Dtsch. Ing.*, **60**, 541, 569 (1916)] derived theoretical relationships for predicting the coefficient of heat transfer for condensation of a pure saturated vapor. A number of simplifying assumptions were used in the derivation.

The **Reynolds number** of the condensate film (falling film) is  $4\Gamma/\mu$ , where  $\Gamma$  is the weight rate of flow (loading rate) of condensate per unit perimeter  $\text{kg}/(\text{s}\cdot\text{m})$  [ $\text{lb}/(\text{h}\cdot\text{ft})$ ]. The thickness of the condensate film for Reynolds number less than 2100 is  $(3\mu\Gamma/\rho^2g)^{1/3}$ .

### Condensation Coefficients

**Vertical Tubes** For the following cases Reynolds number  $< 2100$  and is calculated by using  $\Gamma = W_F/\pi D$ . The **Nusselt equation** for the heat-transfer coefficient for condensate films may be written in the following ways (using liquid physical properties and where  $L$  is the cooled length and  $\Delta t$  is  $t_{sv} - t_s$ ):

Nusselt type:

$$\frac{hL}{k} = 0.943 \left( \frac{L^3 \rho^2 g \lambda}{k \mu \Delta t} \right)^{1/4} = 0.925 \left( \frac{L^3 \rho^2 g}{\mu \Gamma} \right)^{1/3} \quad (5-79)^{\circ}$$

Dimensional:

$$h = b(k^3 \rho^2 D / \mu_b W_F)^{1/3} \quad (5-80)^{\circ}$$

where  $b = 127$  (SI) or 756 (U.S. Customary). For steam at atmospheric pressure,  $k = 0.682 \text{ J}/(\text{m}\cdot\text{s}\cdot\text{K})$  [ $0.394 \text{ Btu}/(\text{h}\cdot\text{ft}\cdot^{\circ}\text{F})$ ],  $\rho = 960 \text{ kg}/\text{m}^3$  ( $60 \text{ lb}/\text{ft}^3$ ),  $\mu_b = (0.28)(10^{-3}) \text{ Pa}\cdot\text{s}$  ( $0.28 \text{ cP}$ ),

$$h = b(D/W_F)^{1/3} \quad (5-81)$$

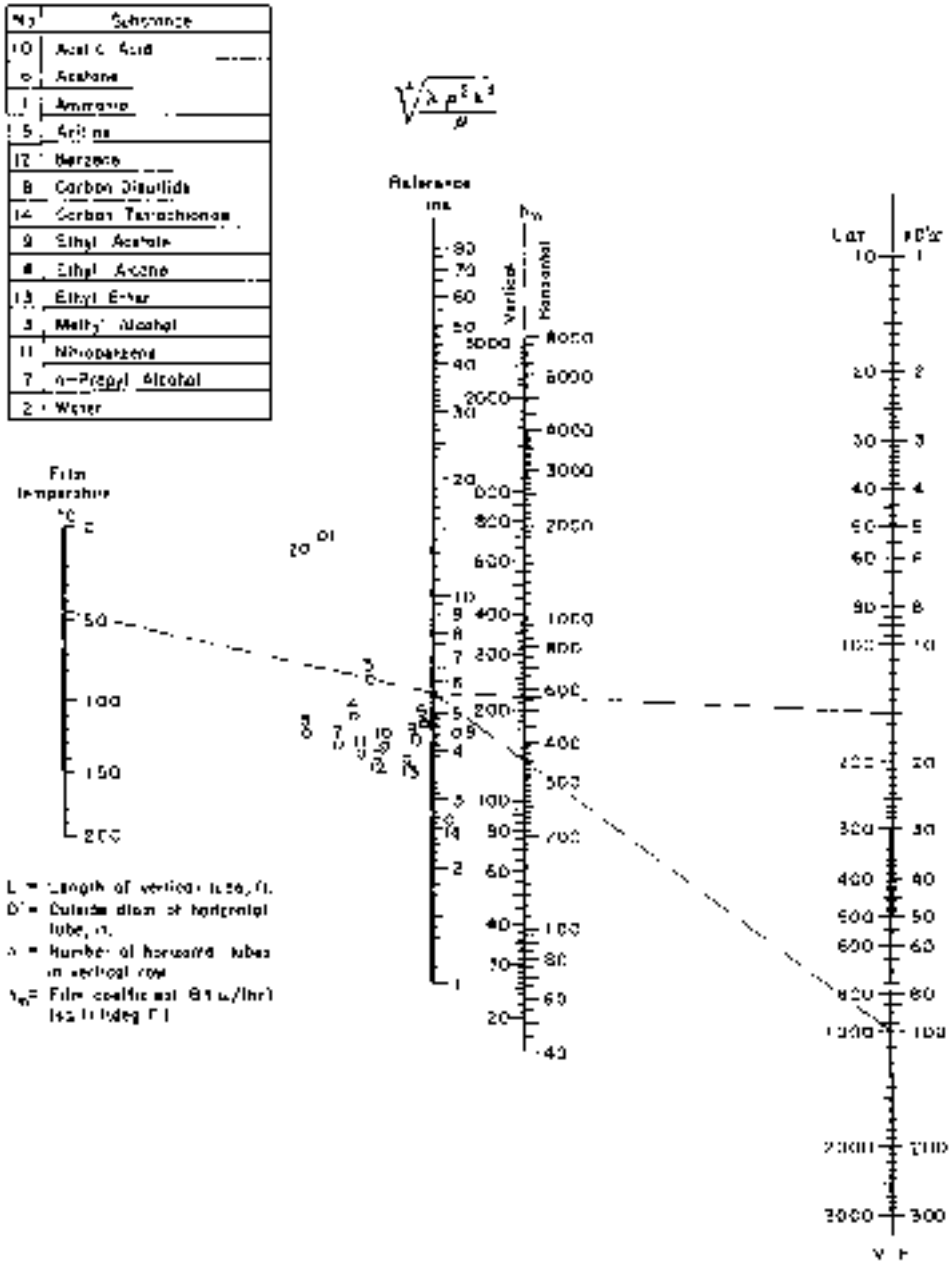

where  $b = 2954$  (SI) or 6978 (U.S. Customary). For organic vapors at normal boiling point,  $k = 0.138 \text{ J}/(\text{m}\cdot\text{s}\cdot\text{K})$  [ $0.08 \text{ Btu}/(\text{h}\cdot\text{ft}\cdot^{\circ}\text{F})$ ],  $\rho = 720 \text{ kg}/\text{m}^3$  ( $45 \text{ lb}/\text{ft}^3$ ),  $\mu_b = (0.35)(10^{-3}) \text{ Pa}\cdot\text{s}$  ( $0.35 \text{ cP}$ ),

$$h = b(D/W_F)^{1/3} \quad (5-82)$$

where  $b = 457$  (SI) or 1080 (U.S. Customary).

**Horizontal Tubes** For the following cases Reynolds number  $< 2100$  and is calculated by using  $\Gamma = W_F/2L$ .

<sup>o</sup> If the vapor density is significant, replace  $\rho^2$  with  $\rho(\rho_l - \rho_v)$ .

**FIG. 5-7** Chart for determining heat-transfer coefficient  $h_m$  for film-type condensation of pure vapor, based on Eqs. (5-79) and (5-83). For vertical tubes multiply  $h_m$  by 1.2. If  $4\Gamma/\mu$  exceeds 2100, use Fig. 5-8.  $\sqrt{\lambda\rho^2g/\mu}$  is in U.S. Customary units; to convert feet to meters, multiply by 0.3048; to convert inches to centimeters, multiply by 2.54; and to convert British thermal units per hour-square foot-degrees Fahrenheit to watts per square meter-kelvins, multiply by 5.6780.

Nusselt type:

$$\frac{hD}{k} = 0.73 \left( \frac{D^3 \rho^2 g \lambda}{k \mu \Delta t} \right)^{1/4} = 0.76 \left( \frac{D^3 \rho^2 g}{\mu \Gamma} \right)^{1/3} \quad (5-83)^\circ$$

Dimensional:

$$h = b(k^3 \rho^2 L / \mu_b W_F)^{1/3} \quad (5-84)^\circ$$

where  $b = 205.4$  (SI) or  $534$  (U.S. Customary). For steam at atmospheric pressure

<sup>o</sup> If the vapor density is significant, replace  $\rho^2$  with  $\rho_1(\rho_1 - \rho_c)$ .

$$h = b(L/W_F)^{1/3} \quad (5-85)$$

where  $b = 2080$  (SI) or  $4920$  (U.S. Customary). For organic vapors at normal boiling point

$$h = b(L/W_F)^{1/3} \quad (5-86)$$

where  $b = 324$  (SI) or  $766$  (U.S. Customary).

Figure 5-7 is a nomograph for determining coefficients of heat transfer for condensation of pure vapors.

**Banks of Horizontal Tubes** ( $Re < 2100$ ) In the idealized case of  $N$  tubes in a vertical row where the total condensate flows smoothly from one tube to the one beneath it, without splashing, and still in laminar flow on the tube, the mean condensing coefficient  $h_N$  for the entire row of  $N$  tubes is related to the condensing coefficient for the top tube  $h_1$  by

$$h_N = h_1 N^{-1/4} \quad (5-87)$$

**Dukler Theory** The preceding expressions for condensation are based on the classical Nusselt theory. It is generally known and conceded that the film coefficients for steam and organic vapors calculated by the Nusselt theory are conservatively low. Dukler [*Chem. Eng. Prog.*, **55**, 62 (1959)] developed equations for velocity and temperature distribution in thin films on vertical walls based on expressions of Deissler (NACA Tech. Notes 2129, 1950; 2138, 1952; 3145, 1959) for the eddy viscosity and thermal conductivity near the solid boundary. According to the Dukler theory, three fixed factors must be known to establish the value of the average film coefficient: the terminal Reynolds number, the Prandtl number of the condensed phase, and a dimensionless group  $N_d$  defined as follows:

$$N_d = (0.250\mu_L^{1.173}\mu_G^{0.16})/(g^{2/3}D^2\rho_L^{0.553}\rho_G^{0.78}) \quad (5-88)$$

Graphical relationships of these variables are available in Document 6058, ADI Auxiliary Publications Project, Library of Congress, Washington. If rigorous values for condensing-film coefficients are desired, especially if the value of  $N_d$  in Eq. (5-88) exceeds  $(1)(10^{-5})$ , it is suggested that these graphs be used. For the case in which interfacial shear is zero, Fig. 5-8 may be used. It is interesting to note that, according to the Dukler development, there is no definite transition Reynolds number; deviation from Nusselt theory is less at low Reynolds numbers; and when the Prandtl number of a fluid is less than 0.4 (at Reynolds number above 1000), the predicted values for film coefficient are lower than those predicted by the Nusselt theory.

The Dukler theory is applicable for condensate films on horizontal tubes and also for falling films, in general, i.e., those not associated with condensation or vaporization processes.

**Vapor Shear Controlling** For vertical in-tube condensation with vapor and liquid flowing concurrently downward, if gravity controls, Figs. 5-7 and 5-8 may be used. If vapor shear controls, the Carpenter-Colburn correlation (*General Discussion on Heat Transfer*, London, 1951, ASME, New York, p. 20) is applicable:

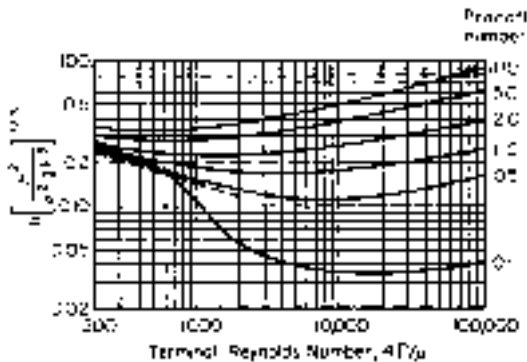

$$h\mu_i/k_i\rho_i^{1/2} = 0.065(\text{Pr})^{1/2}F_{vc}^{1/2} \quad (5-89a)$$

$$\text{where } F_{vc} = fG_{vm}^2/2\rho_v \quad (5-89b)$$

$$G_{vm} = \left( \frac{G_{vi}^2 + G_{vi}G_{vo} + G_{vo}^2}{3} \right)^{1/2} \quad (5-89c)$$

and  $f$  is the Fanning friction factor evaluated at

$$(\text{Re})_{vm} = D_i G_{vm} / \mu_v \quad (5-89d)$$

**FIG. 5-8** Dukler plot showing average condensing-film coefficient as a function of physical properties of the condensate film and the terminal Reynolds number. (Dotted line indicates Nusselt theory for Reynolds number  $< 2100$ .) [Reproduced by permission from *Chem. Eng. Prog.*, **55**, 64 (1959).]

and the subscripts  $vi$  and  $vo$  refer to the vapor inlet and outlet, respectively. An alternative formulation, directly in terms of the friction factor, is

$$h = 0.065 (c\rho k_f/2\mu_v)^{1/2} G_{vm} \quad (5-89e)$$

expressed in consistent units.

Another correlation for vapor-shear-controlled condensation is the Boyko-Kruzhilin correlation [*Int. J. Heat Mass Transfer*, **10**, 361 (1967)], which gives the mean condensing coefficient for a stream between inlet quality  $x_i$  and outlet quality  $x_o$ :

$$\frac{hD_i}{k_l} = 0.024 \left( \frac{D_i G_T}{\mu_l} \right)^{0.8} (\text{Pr})_l^{0.43} \frac{\sqrt{(\rho/\rho_m)_i} + \sqrt{(\rho/\rho_m)_o}}{2} \quad (5-90a)$$

where  $G_T$  = total mass velocity in consistent units

$$\left( \frac{\rho}{\rho_m} \right)_i = 1 + \frac{\rho_l - \rho_v}{\rho_v} x_i \quad (5-90b)$$

$$\left( \frac{\rho}{\rho_m} \right)_o = 1 + \frac{\rho_l - \rho_v}{\rho_v} x_o \quad (5-90c)$$

For horizontal in-tube condensation at low flow rates Kern's modification (*Process Heat Transfer*, McGraw-Hill, New York, 1950) of the Nusselt equation is valid:

$$h_m = 0.761 \left[ \frac{Lk_l^3 \rho_l (\rho_l - \rho_v) g}{W_F \mu_l} \right]^{1/3} = 0.815 \left[ \frac{k_l^3 \rho_l (\rho_l - \rho_v) g \lambda}{\pi \mu_l D_i \Delta t} \right]^{1/4} \quad (5-91)$$

where  $W_F$  is the total vapor condensed in one tube and  $\Delta t$  is  $t_{sc} - t_s$ . A more rigorous correlation has been proposed by Chaddock [*Refrig. Eng.*, **65**(4), 36 (1957)]. Use consistent units.

At high condensing loads, with vapor shear dominating, tube orientation has no effect, and Eq. (5-90a) may also be used for horizontal tubes.

Condensation of pure vapors under laminar conditions in the presence of noncondensable gases, interfacial resistance, superheating, variable properties, and diffusion has been analyzed by Minkowycz and Sparrow [*Int. J. Heat Mass Transfer*, **9**, 1125 (1966)].

**BOILING (VAPORIZATION) OF LIQUIDS**

**Boiling Mechanisms** Vaporization of liquids may result from various mechanisms of heat transfer, singly or combinations thereof. For example, vaporization may occur as a result of heat absorbed, by radiation and convection, at the surface of a pool of liquid; or as a result of heat absorbed by natural convection from a hot wall beneath the disengaging surface, in which case the vaporization takes place when the superheated liquid reaches the pool surface. Vaporization also occurs from falling films (the reverse of condensation) or from the flashing of liquids superheated by forced convection under pressure.

**Pool boiling** refers to the type of boiling experienced when the heating surface is surrounded by a relatively large body of fluid which is not flowing at any appreciable velocity and is agitated only by the motion of the bubbles and by natural-convection currents. Two types of pool boiling are possible: subcooled pool boiling, in which the bulk fluid temperature is below the saturation temperature, resulting in collapse of the bubbles before they reach the surface, and saturated pool boiling, with bulk temperature equal to saturation temperature, resulting in net vapor generation.

The general shape of the curve relating the heat-transfer coefficient to  $\Delta t_b$ , the temperature driving force (difference between the wall temperature and the bulk fluid temperature) is one of the few parametric relations that are reasonably well understood. The familiar boiling curve was originally demonstrated experimentally by Nukiyama [*J. Soc. Mech. Eng. (Japan)*, **37**, 367 (1934)]. This curve points out one of the great dilemmas for boiling-equipment designers. They are faced with at least six heat-transfer regimes in pool boiling: natural convection (+), incipient nucleate boiling (+), nucleate boiling (+), transition to film boiling (-), stable film boiling (+), and film boiling with increasing radiation (+). The signs indicate the sign of the derivative  $d(q/A)/d \Delta t_b$ . In the transition to film boiling, heat-transfer rate decreases with driving force. The regimes of greatest commercial interest are the nucleate-boiling and stable-film-boiling regimes.

Heat transfer by nucleate boiling is an important mechanism in the vaporization of liquids. It occurs in the vaporization of liquids in

kettle-type and natural-circulation reboilers commonly used in the process industries. High rates of heat transfer per unit of area (heat flux) are obtained as a result of bubble formation at the liquid-solid interface rather than from mechanical devices external to the heat exchanger. There are available several expressions from which reasonable values of the film coefficients may be obtained.

The boiling curve, particularly in the nucleate-boiling region, is significantly affected by the temperature driving force, the total system pressure, the nature of the boiling surface, the geometry of the system, and the properties of the boiling material. In the nucleate-boiling regime, heat flux is approximately proportional to the cube of the temperature driving force. Designers in addition must know the minimum  $\Delta t$  (the point at which nucleate boiling begins), the critical  $\Delta t$  (the  $\Delta t$  above which transition boiling begins), and the maximum heat flux (the heat flux corresponding to the critical  $\Delta t$ ). For designers who do not have experimental data available, the following equations may be used.

**Boiling Coefficients** For the nucleate-boiling coefficient the Mostinski equation [*Teplenergetika*, **4**, 66 (1963)] may be used:

$$h = b P_c^{0.69} \left(\frac{q}{A}\right)^{0.7} \left[ 1.8 \left(\frac{P}{P_c}\right)^{0.17} + 4 \left(\frac{P}{P_c}\right)^{1.2} + 10 \left(\frac{P}{P_c}\right)^{10} \right] \quad (5-92)$$

where  $b = (3.75)(10^{-5})$  (SI) or  $(2.13)(10^{-4})$  (U.S. Customary),  $P_c$  is the critical pressure and  $P$  the system pressure,  $q/A$  is the heat flux, and  $h$  is the nucleate-boiling coefficient. The McNelly equation [*J. Imp. Coll. Chem. Eng. Soc.*, 7(18), (1953)] may also be used:

$$h = 0.225 \left(\frac{q c_l}{A \lambda}\right)^{0.69} \left(\frac{P k_l}{\sigma}\right)^{0.31} \left(\frac{p_l}{p_c} - 1\right)^{0.33} \quad (5-93)$$

where  $c_l$  is the liquid heat capacity,  $\lambda$  is the latent heat,  $P$  is the system pressure,  $k_l$  is the thermal conductivity of the liquid, and  $\sigma$  is the surface tension.

An equation of the Nusselt type has been suggested by Rohsenow [*Trans. Am. Soc. Mech. Eng.*, **74**, 969 (1952)].

$$h D/k = C_r (D G/\mu)^{2/3} (c\mu/k)^{-0.7} \quad (5-94a)$$

in which the variables assume the following form:

$$\frac{h \beta'}{k} \left[ \frac{g_c \sigma}{g(\rho_L - \rho_v)} \right]^{1/2} = C_r \left[ \frac{\beta'}{\mu} \left( \frac{g_c \sigma}{g(\rho_L - \rho_v)} \right)^{1/2} \frac{W}{A} \right]^{2/3} \left( \frac{c\mu}{k} \right)^{-0.7} \quad (5-94b)$$

The coefficient  $C_r$  is not truly constant but varies from 0.006 to 0.015.\* It is possible that the nature of the surface is partly responsible for the variation in the constant. The only factor in Eq. (5-94b) not readily available is the value of the contact angle  $\beta'$ .

Another Nusselt-type equation has been proposed by Forster and Zuber:†

$$Nu = 0.0015 Re^{0.62} Pr^{1/3} \quad (5-95)$$

which takes the following form:

$$\frac{c \rho_L \sqrt{\pi \alpha}}{k \rho_v} \frac{W}{A} \left( \frac{2\sigma}{\Delta p} \right)^{1/2} \left( \frac{\rho_L}{\Delta p g_c} \right)^{1/4} = 0.0015 \left[ \frac{\rho_L}{\mu} \left( \frac{c \rho_L \Delta T \sqrt{\pi \alpha}}{\lambda \rho_v} \right)^2 \right]^{0.62} \left( \frac{c\mu}{k} \right)^{1/2} \quad (5-96)$$

where  $\alpha = k/\rho c$  (all liquid properties)

$\Delta p$  = pressure of the vapor in a bubble minus saturation pressure of a flat liquid surface

Equations (5-94b) and (5-96) have been arranged in dimensional form by Westwater.

The numerical constant may be adjusted to suit any particular set of data if one desires to use a certain criterion. However, surface conditions vary so greatly that deviations may be as large as  $\pm 25$  percent from results obtained.

The **maximum heat flux** may be predicted by the Kutateladse-Zuber [*Trans. Am. Soc. Mech. Eng.*, **80**, 711 (1958)] relationship, using consistent units:

$$\left(\frac{q}{A}\right)_{\max} = 0.18 g_c^{1/4} \rho_v \lambda \left[ \frac{(\rho_l - \rho_v) \sigma g_c}{\rho_v^2} \right]^{1/4} \quad (5-97)$$

Alternatively, Mostinski presented an equation which approximately represents the Cichelli-Bonilla [*Trans. Am. Inst. Chem. Eng.*, **41**, 755 (1945)] correlation:

$$\frac{(q/A)_{\max}}{P_c} = b \left(\frac{P}{P_c}\right)^{0.35} \left(1 - \frac{P}{P_c}\right)^{0.9} \quad (5-98)$$

where  $b = 0.368$  (SI) or  $5.58$  (U.S. Customary);  $P_c$  is the critical pressure,  $P$  absolute;  $P$  is the system pressure; and  $(q/A)_{\max}$  is the maximum heat flux.

The lower limit of applicability of the nucleate-boiling equations is from 0.1 to 0.2 of the maximum limit and depends upon the magnitude of natural-convection heat transfer for the liquid. The best method of determining the lower limit is to plot two curves: one of  $h$  versus  $\Delta t$  for natural convection, the other of  $h$  versus  $\Delta t$  for nucleate boiling. The intersection of these two curves may be considered the lower limit of applicability of the equations.

These equations apply to single tubes or to flat surfaces in a large pool. In tube bundles the equations are only approximate, and designers must rely upon experiment. Palen and Small [*Hydrocarbon Process.*, **43**(11), 199 (1964)] have shown the effect of tube-bundle size on maximum heat flux.

$$\left(\frac{q}{A}\right)_{\max} = b \frac{P}{D_o \sqrt{N_T}} \rho_v \lambda \left[ \frac{g \sigma (\rho_l - \rho_v)}{\rho_v^2} \right]^{1/4} \quad (5-99)$$

where  $b = 0.43$  (SI) or  $61.6$  (U.S. Customary),  $p$  is the tube pitch,  $D_o$  is the tube outside diameter, and  $N_T$  is the number of tubes (twice the number of complete tubes for U-tube bundles).

For **film boiling**, Bromley's [*Chem. Eng. Prog.*, **46**, 221 (1950)] correlation may be used:

$$h = b \left[ \frac{k_v^3 (\rho_l - \rho_v) \rho_v g}{\mu_v D_o \Delta t_b} \right]^{1/4} \quad (5-100)$$

where  $b = 4.306$  (SI) or  $0.620$  (U.S. Customary). Katz, Myers, and Balekjian [*Pet. Refiner*, **34**(2), 113 (1955)] report boiling heat-transfer coefficients on finned tubes.

## INTRODUCTION

Heat transfer by thermal radiation involves the transport of electromagnetic (EM) energy from a source to a sink. In contrast to other modes of heat transfer, radiation does not require the presence of an intervening medium, e.g., as in the irradiation of the earth by the sun. Most industrially important applications of radiative heat transfer occur in the *near infrared* portion of the EM spectrum (0.7 through 25  $\mu\text{m}$ ) and may extend into the *far infrared* region (25 to 1000  $\mu\text{m}$ ). For very high temperature sources, such as solar radiation, relevant wavelengths encompass the entire *visible region* (0.4 to 0.7  $\mu\text{m}$ ) and may extend down to 0.2  $\mu\text{m}$  in the *ultraviolet* (0.01- to 0.4- $\mu\text{m}$ ) portion of the EM spectrum. Radiative transfer can also exhibit unique *action-at-a-distance* phenomena which do not occur in other modes of heat transfer. Radiation differs from conduction and convection not only with regard to mathematical characterization but also with regard to its fourth power dependence on temperature. Thus it is usually dominant in high-temperature combustion applications. The temperature at which radiative transfer accounts for roughly one-half of the total heat loss from a surface in air depends on such factors as surface **emissivity** and the convection coefficient. For pipes in free convection, radiation is important at ambient temperatures. For fine wires of low emissivity it becomes important at temperatures associated with bright red heat (1300 K). Combustion gases at furnace temperatures typically lose more than 90 percent of their energy by radiative emission from constituent carbon dioxide, water vapor, and particulate matter. Radiative transfer methodologies are important in myriad engineering applications. These include semiconductor processing, illumination theory, and gas turbines and rocket nozzles, as well as furnace design.

## THERMAL RADIATION FUNDAMENTALS

In a vacuum, the wavelength  $\lambda$ , frequency,  $\nu$  and wavenumber  $\eta$  for electromagnetic radiation are interrelated by  $\lambda = c/\nu = 1/\eta$ , where  $c$  is the speed of light. Frequency is independent of the index of refraction of a medium  $n$ , but both the speed of light and the wavelength in the medium vary according to  $c_m = c/n$  and  $\lambda_m = \lambda/n$ . When a radiation beam passes into a medium of different refractive index, not only does its wavelength change but so does its direction (Snell's law) as well as the magnitude of its intensity. In most engineering heat-transfer calculations, wavelength is usually employed to characterize radiation while wave number is often used in gas spectroscopy. For a vacuum, air at ambient conditions, and most gases,  $n \approx 1.0$ . For this reason this presentation sometimes does not distinguish between  $\lambda$  and  $\lambda_m$ . *Dielectric materials* exhibit  $1.4 < n < 4$ , and the speed of light decreases considerably in such media.

In radiation heat transfer, the **monochromatic intensity**  $I_\lambda \equiv I_\lambda(\vec{r}, \vec{\Omega}, \lambda)$ , is a *fundamental* (scalar) *field variable* which characterizes EM energy transport. Intensity defines the radiant energy flux passing through an infinitesimal area  $dA$ , oriented *normal* to a radiation beam of arbitrary direction  $\vec{\Omega}$ . At steady state, the monochromatic intensity is a function of position  $\vec{r}$ , direction  $\vec{\Omega}$ , and wavelength and has units of  $\text{W}/(\text{m}^2 \cdot \text{sr} \cdot \mu\text{m})$ . In the general case of an *absorbing-emitting* and *scattering* medium, characterized by some absorption coefficient  $K(\text{m}^{-1})$ , intensity in the direction  $\vec{\Omega}$  will be modified by attenuation and by *scattering* of radiation into and out of the beam. For the special case of a nonabsorbing (transparent), nonscattering, medium of constant refractive index, the radiation intensity is *constant and independent of position in a given direction*  $\vec{\Omega}$ . This circumstance arises in *illumination theory* where the light intensity in a room is constant in a *given direction* but may vary with respect to *all other directions*. The basic conservation law for radiation intensity is termed the *equation of transfer* or *radiative transfer equation*. The equation of transfer is a *directional* energy balance and mathematically is an *integrodifferential equation*. The relevance of the transport equation to radiation heat transfer is discussed in many sources; see, e.g., Modest, M. F., *Radiative Heat Transfer*, 2d ed., Academic Press, 2003, or Siegel, R., and J. R. Howell, *Thermal Radiative Heat Transfer*, 4th ed., Taylor & Francis, New York, 2001.

**Introduction to Radiation Geometry** Consider a homogeneous medium of constant refractive index  $n$ . A pencil of radiation

originates at differential area element  $dA_i$  and is incident on differential area element  $dA_j$ . Designate  $\vec{n}_i$  and  $\vec{n}_j$  as the unit vectors normal to  $dA_i$  and  $dA_j$ , and let  $r_j$  with unit direction vector  $\vec{\Omega}$ , define the distance of separation between the area elements. Moreover,  $\phi_i$  and  $\phi_j$  denote the *confined angles* between  $\vec{\Omega}$  and  $\vec{n}_i$  and  $\vec{n}_j$ , respectively [i.e.,  $\cos\phi_i \equiv \cos(\vec{\Omega}, \vec{r}_i)$  and  $\cos\phi_j \equiv \cos(\vec{\Omega}, \vec{r}_j)$ ]. As the beam travels toward  $dA_j$ , it will *diverge* and subtend a solid angle

$$d\Omega_j = \frac{\cos\phi_j}{r_j^2} dA_j \text{ sr}$$

at  $dA_j$ . Moreover, the projected area of  $dA_i$  in the direction of  $\vec{\Omega}$  is given by  $\cos(\vec{\Omega}, \vec{r}_i) dA_i = \cos\phi_i dA_i$ . Multiplication of the intensity  $I_\lambda \equiv I_\lambda(\vec{r}, \vec{\Omega}, \lambda)$  by  $d\Omega_j$  and the apparent area of  $dA_i$ , then yields an expression for the (*differential*) *net monochromatic radiant energy flux*  $dQ_{i,j}$  originating at  $dA_i$  and intercepted by  $dA_j$ .

$$dQ_{i,j} \equiv I_\lambda(\vec{r}, \vec{\Omega}, \lambda) \cos\phi_i \cos\phi_j dA_i dA_j / r_j^2 \quad (5-101)$$

The **hemispherical emissive power**<sup>\*</sup>  $E$  is defined as the radiant flux density ( $\text{W}/\text{m}^2$ ) associated with emission from an element of surface area  $dA$  into a surrounding unit hemisphere whose base is coplanar with  $dA$ . If the monochromatic intensity  $I_\lambda(\vec{\Omega}, \lambda)$  of emission from the surface is *isotropic* (independent of the angle of emission,  $\vec{\Omega}$ ), Eq. (5-101) may be integrated over the  $2\pi$  sr of the surrounding unit hemisphere to yield the simple relation  $E_\lambda = \pi I_\lambda$ , where  $E_\lambda \equiv E_\lambda(\lambda)$  is defined as the monochromatic or *spectral* hemispherical emissive power.

**Blackbody Radiation** Engineering calculations involving thermal radiation normally employ the **hemispherical blackbody emissive power** as the thermal driving force analogous to temperature in the cases of conduction and convection. A **blackbody** is a theoretical idealization for a *perfect theoretical radiator*; i.e., it absorbs all incident radiation without reflection and emits isotropically. In practice, soot-covered surfaces sometimes approximate blackbody behavior. Let  $E_{b,\lambda} = E_{b,\lambda}(T, \lambda)$  denote the monochromatic blackbody hemispherical emissive power *frequency function* defined such that  $E_{b,\lambda}(T, \lambda) d\lambda$  represents the fraction of blackbody energy lying in the wavelength region from  $\lambda$  to  $\lambda + d\lambda$ . The function  $E_{b,\lambda} = E_{b,\lambda}(T, \lambda)$  is given by **Planck's law**

$$\frac{E_{b,\lambda}(T, \lambda)}{n^2 T^5} = \frac{c_1 (\lambda T)^{-5}}{e^{c_2/\lambda T} - 1} \quad (5-102)$$

where  $c_1 = 2\pi^5 h c^2$  and  $c_2 = hc/k$  are defined as Planck's first and second constants, respectively.

Integration of Eq. (5-102) over all wavelengths yields the **Stefan-Boltzman law** for the hemispherical blackbody emissive power

$$E_b(T) = \int_{\lambda=0}^{\infty} E_{b,\lambda}(T, \lambda) d\lambda = n^2 \sigma T^4 \quad (5-103)$$

where  $\sigma = c_1(\pi/c_2)^4/15$  is the Stephan-Boltzman constant. Since a blackbody is an *isotropic emitter*, it follows that the intensity of blackbody emission is given by the simple formula  $I_b = E_b/\pi = n^2 \sigma T^4/\pi$ . The intensity of radiation emitted over all wavelengths by a blackbody is thus uniquely determined by its temperature. In this presentation, all references to hemispherical emissive power shall be to the *blackbody* emissive power, and the subscript  $b$  may be suppressed for expediency.

For short wavelengths  $\lambda T \rightarrow 0$ , the asymptotic form of Eq. (5-102) is known as the **Wien equation**

$$\frac{E_{b,\lambda}(T, \lambda)}{n^2 T^5} \equiv c_1 (\lambda T)^{-5} e^{-c_2/\lambda T} \quad (5-104)$$

The error introduced by use of the Wien equation is less than 1 percent when  $\lambda T < 3000 \mu\text{m} \cdot \text{K}$ . The Wien equation has significant practical value in optical pyrometry for  $T < 4600 \text{ K}$  when a red filter ( $\lambda = 0.65 \mu\text{m}$ ) is employed. The long-wavelength asymptotic approximation for Eq. (5-102) is known as the **Rayleigh-Jeans formula**, which is accurate to within 1 percent for  $\lambda T > 778,000 \mu\text{m} \cdot \text{K}$ . The Rayleigh-Jeans formula is of limited engineering utility since a blackbody emits over 99.9 percent of its total energy below the value of  $\lambda T = 53,000 \mu\text{m} \cdot \text{K}$ .

<sup>\*</sup> In the literature the emissive power is variously called the emittance, total hemispherical intensity, or radiant flux density.

**Nomenclature and Units—Radiative Transfer**

|  |  |
|--|--|
| $a, a_g, a_{g,1}$  | WSGG spectral model clear plus gray weighting constants            |
| $\bar{C}_p, \bar{C}_{p,prod}$                                      | Heat capacity per unit mass, $J \cdot kg^{-1} \cdot K^{-1}$        |
| $ij = s_i s_j$   | Shorthand notation for direct exchange area                        |
| $A, A_i$   | Area of enclosure or zone $i$ , $m^2$                              |
| $c$  | Speed of light in vacuum, $m/s$                                    |
| $c_1, c_2$   | Planck's first and second constants, $W \cdot m^2$ and $m \cdot K$ |
| $d_p, r_p$   | Particle diameter and radius, $\mu m$                              |
| $E_{b,\lambda} = E_{b,\lambda}(T, \lambda)$                        | Monochromatic, blackbody emissive power, $W/(m^2 \cdot \mu m)$     |
| $E_n(x)$   | Exponential integral of order $n$ , where $n = 1, 2, 3, \dots$     |
| $E$  | Hemispherical emissive power, $W/m^2$                              |
| $E_b = n^2 \sigma T^4$   | Hemispherical blackbody emissive power, $W/m^2$                    |
| $f_c$  | Volumetric fraction of soot  |
| $F_b(\lambda T)$   | Blackbody fractional energy distribution                           |
| $F_{ij}$   | Direct view factor from surface zone $i$ to surface zone $j$       |
| $\bar{F}_{ij}$   | Refractory augmented black view factor; $F$ -bar                   |
| $F_{i,j}$  | Total view factor from surface zone $i$ to surface zone $j$        |
| $h$  | Planck's constant, $J \cdot s$                                     |
| $h_i$  | Heat-transfer coefficient, $W/(m^2 \cdot K)$                       |
| $H_i$  | Incident flux density for surface zone $i$ , $W/m^2$               |
| $H$  | Enthalpy rate, $W$   |
| $\dot{H}_f$  | Enthalpy feed rate, $W$  |
| $\dot{I}_\lambda \equiv I_\lambda(\vec{r}, \vec{\Omega}, \lambda)$ | Monochromatic radiation intensity, $W/(m^2 \cdot \mu m \cdot sr)$  |
| $k$  | Boltzmann's constant, $J/K$  |
| $k_{\lambda,p}$  | Monochromatic line absorption coefficient, $(atm \cdot m)^{-1}$    |
| $K$  | Gas absorption coefficient, $m^{-1}$                               |
| $L_M, L_{M0}$  | Average and optically thin mean beam lengths, $m$                  |
| $\dot{m}$  | Mass flow rate, $kg/h^{-1}$  |
| $n$  | Index of refraction  |
| $M, N$   | Number of surface and volume zones in enclosure                    |
| $p_k$  | Partial pressure of species $k$ , $atm$                            |
| $P$  | Number of WSGG gray gas spectral windows                           |
| $Q_i$  | Total radiative flux originating at surface zone $i$ , $W$         |
| $Q_{ij}$   | Net radiative flux between zone $i$ and zone $j$ , $W$             |
| $T$  | Temperature, $K$   |
| $U$  | Overall heat-transfer coefficient in WSCC model                    |
| $V$  | Enclosure volume, $m^3$  |
| $W$  | Leaving flux density (radiosity), $W/m^2$                          |

**Greek Characters**

|  |   |
|--|---|
| $\alpha, \alpha_{1,2}$                 | Surface absorptivity or absorptance; subscript 1 refers to the surface temperature while subscript 2 refers to the radiation source |
| $\alpha_{g,1}, \epsilon_g, \tau_{g,1}$ | Gas absorptivity, emissivity, and transmissivity  |
| $\beta$                                | Dimensionless constant in mean beam length equation, $L_M = \beta L_{M0}$   |
| $\Delta T_{fit} \equiv T_g - T_e$      | Adjustable temperature fitting parameter for WSCC model, $K$  |
| $\epsilon$                             | Gray diffuse surface emissivity   |
| $\epsilon_g(T, r)$                     | Gas emissivity with path length $r$   |
| $\epsilon'_g(T, \Omega, \lambda)$      | Monochromatic, unidirectional, surface emissivity   |
| $\eta = 1/\lambda$                     | Wave number in vacuum, $cm^{-1}$  |
| $\lambda = c/\nu$                      | Wavelength in vacuum, $\mu m$   |
| $\nu$                                  | Frequency, $Hz$   |
| $\rho = 1 - \epsilon$                  | Diffuse reflectivity  |
| $\sigma$                               | Stefan-Boltzmann constant, $W/(m^2 \cdot K^4)$  |
| $\Sigma$                               | Number of unique direct surface-to-surface direct exchange areas  |
| $\tau_g = 1 - \epsilon_g$              | Gas transmissivity  |
| $\Omega$                               | Solid angle, $sr$ (steradians)  |
| $\Phi$                                 | Equivalence ratio of fuel and oxidant   |
| $\Psi^{(3)}(x)$                        | Pentagramma function of $x$   |
| $\omega$                               | Albedo for single scatter   |

**Dimensionless Quantities**

|   |                              |
|---|------------------------------|
| $D_{eff} = \frac{N_{FD}}{(S_i G_R/A_1) + N_{CR}}$ | Effective firing density     |
| $N_{CR} = \frac{h}{4\sigma T_{g,1}^3}$            | Convection-radiation number  |
| $N_{FD} = \dot{H}_f / \sigma T_{ref}^4 A_1$       | Dimensionless firing density |
| $\eta_g$  | Gas-side furnace efficiency  |
| $\eta'_g = \eta_g(1 - \Theta_0)$                  | Reduced furnace efficiency   |
| $\Theta_i = T_i / T_{ref}$                        | Dimensionless temperature    |

**Vector Notation**

|                             |   |
|-----------------------------|---|
| $\vec{n}_i$ and $\vec{n}_j$ | Unit vectors normal to differential area elements $dA_i$ and $dA_j$ |
| $\vec{r}$                   | Position vector   |
| $\vec{\Omega}$              | Arbitrary unit direction vector                                     |

**Matrix Notation**

|  |   |
|--|---|
| $\mathbf{I}_M$   | Column vector; all of whose elements are unity, $[M \times 1]$  |
| $\mathbf{I} = [\delta_{ij}]$   | Identity matrix, where $\delta_{ij}$ is the Kronecker delta; i.e., $\delta_{ij} = 1$ for $i = j$ and $\delta_{ij} = 0$ for $i \neq j$ . |
| $\mathbf{aI}$  | Diagonal matrix of WSGG gray gas surface zone $a$ -weighting factors $[M \times M]$   |
| $\mathbf{a}_g \mathbf{I}$  | Diagonal matrix of gray gas WSGG volume zone $a$ -weighting factors $[N \times N]$  |
| $\mathbf{A} = [A_{ij}]$  | Arbitrary nonsingular square matrix   |
| $\mathbf{A}^T = [A_{ji}]$  | Transpose of $\mathbf{A}$   |
| $\mathbf{A}^{-1} = [A_{ij}]^{-1}$  | Inverse of $\mathbf{A}$   |
| $\mathbf{DI} = [D_i \delta_{ij}]$  | Arbitrary diagonal matrix   |
| $\mathbf{DI}^{-1} = [\delta_{ij}/D_i]$   | Inverse of diagonal matrix  |
| $\mathbf{CDI}$   | $\mathbf{CI} \cdot \mathbf{DI} = [C_i D_i \delta_{ij}]$ , product of two diagonal matrices  |
| $\mathbf{AI} = [A_i \delta_{ij}]$  | Diagonal matrix of surface zone areas, $m^2 [M \times M]$   |
| $\epsilon \mathbf{I} = [\epsilon_i \delta_{ij}]$                                   | Diagonal matrix of diffuse zone emissivities $[M \times M]$   |
| $\rho \mathbf{I} = [\rho_i \delta_{ij}]$   | Diagonal matrix of diffuse zone reflectivities $[M \times M]$   |
| $\mathbf{E} = [E_i] = [\sigma T_i^4]$  | Column vector of surface blackbody hemispherical emissive powers, $W/m^2 [M \times 1]$  |
| $\mathbf{EI} = [E_i \delta_{ij}] = [\sigma T_i^4 \delta_{ij}]$                     | Diagonal matrix of surface blackbody emissive powers, $W/m^2 [M \times M]$  |
| $\mathbf{E}_g = [E_{g,i}] = [\sigma T_{g,i}^4]$                                    | Column vector of gas blackbody hemispherical emissive powers, $W/m^2 [N \times 1]$  |
| $\mathbf{E}_g \mathbf{I} = [E_{g,i} \delta_{ij}] = [\sigma T_{g,i}^4 \delta_{ij}]$ | Diagonal matrix of gas blackbody emissive powers, $W/m^2 [N \times N]$  |
| $\mathbf{H} = [H_i]$   | Column vector of surface zone incident flux densities, $W/m^2 [M \times 1]$   |
| $\mathbf{W} = [W_i]$   | Column vector of surface zone leaving flux densities, $W/m^2 [M \times 1]$  |
| $\mathbf{Q} = [Q_i]$   | Column vector of surface zone fluxes, $W [M \times 1]$  |
| $\mathbf{R} = [\mathbf{AI} - \mathbf{ss} \cdot \rho \mathbf{I}]^{-1}$              | Inverse multiple-reflection matrix, $m^{-2} [M \times M]$   |
| $\mathbf{KI}_p = [\delta_{ij} K_{p,i}]$  | Diagonal matrix of WSGG $K_{p,i}$ values for the $i$ th zone and $p$ th gray gas component, $m^{-1} [N \times N]$                       |
| $\overline{\mathbf{KI}}$   | Diagonal matrix of WSGG-weighted gray gas absorption coefficients, $m^{-1} [N \times N]$  |
| $\mathbf{S}'$  | Column vector for net volume absorption, $W [N \times 1]$   |
| $\overline{\mathbf{ss}} = [\overline{s_i s_j}]$                                    | Array of direct surface-to-surface exchange areas, $m^2 [M \times M]$   |
| $\overline{\mathbf{sg}} = [\overline{s_i g_j}] = \overline{\mathbf{gs}}^T$         | Array of direct gas-to-surface exchange areas, $m^2 [M \times N]$   |
| $\overline{\mathbf{gg}} = [\overline{g_i g_j}]$                                    | Array of direct gas-to-gas exchange areas, $m^2 [N \times N]$   |
| $\overline{\mathbf{SS}} = [\overline{S_i S_j}]$                                    | Array of total surface-to-surface exchange areas, $m^2 [M \times M]$  |
| $\overline{\mathbf{SG}} = [\overline{S_i G_j}]$                                    | Array of total gas-to-surface exchange areas, $m^2 [M \times N]$  |
| $\overline{\mathbf{GS}} = \overline{\mathbf{GS}}^T$                                | Array of total surface-to-gas exchange areas, $m^2 [N \times M]$  |
| $\overline{\mathbf{GG}} = [\overline{G_i G_j}]$                                    | Array of total gas-to-gas exchange areas, $m^2 [N \times N]$  |
| $\overline{\mathbf{SS}} = [\overline{S_i S_i}]$                                    | Array of directed surface-to-surface exchange areas, $m^2 [M \times M]$   |
| $\overline{\mathbf{SG}} = [\overline{S_i G_j}]$                                    | Array of directed gas-to-surface exchange areas, $m^2 [M \times N]$   |
| $\overline{\mathbf{GS}} \neq \overline{\mathbf{SG}}^T$                             | Array of directed surface-to-gas exchange areas, $m^2 [N \times M]$   |
| $\overline{\mathbf{GG}} = [\overline{G_i G_i}]$                                    | Array of directed gas-to-gas exchange areas, $m^2 [N \times N]$   |
| $\mathbf{VI} = [V_i \delta_{ij}]$  | Diagonal matrix of zone volumes, $m^3 [N \times N]$   |

**Subscripts**

|           |  |
|-----------|--|
| $b$       | Blackbody or denotes a black surface zone      |
| $f$       | Denotes flux surface zone                      |
| $h$       | Denotes hemispherical surface emissivity       |
| $i, j$    | Zone number indices                            |
| $n$       | Denotes normal component of surface emissivity |
| $p$       | Index for $p$ th gray gas window               |
| $r$       | Denotes refractory surface zone                |
| $s$       | Denotes source-sink surface zone               |
| $\lambda$ | Denotes monochromatic variable                 |
| Ref       | Denotes reference quantity                     |

The blackbody fractional energy *distribution function* is defined by

$$F_b(\lambda T) = \frac{\int_0^\lambda E_{b,\lambda}(T, \lambda) d\lambda}{\int_0^\infty E_{b,\lambda}(T, \lambda) d\lambda} \quad (5-105)$$

The function  $F_b(\lambda T)$  defines the fraction of total energy in the blackbody spectrum which lies below  $\lambda T$  and is a unique function of  $\lambda T$ . For purposes of digital computation, the following series expansion for  $F_b(\lambda T)$  proves especially useful.

$$F_b(\lambda T) = \frac{15}{\pi^4} \sum_{k=1}^{\infty} \frac{e^{-k\xi}}{k} \left( \xi^3 + \frac{3\xi^2}{k} + \frac{6\xi}{k^2} + \frac{6}{k^3} \right) \text{ where } \xi = \frac{c_2}{\lambda T} \quad (5-106)$$

Equation (5-106) converges rapidly and is due to Lowan [1941] as referenced in Chang and Rhee [*Int. Comm. Heat Mass Transfer*, **11**, 451-455 (1984)].

Numerically, in the preceding,  $h = 6.6260693 \times 10^{-34}$  J·s is the Planck constant;  $c = 2.99792458 \times 10^8$  m/s is the velocity of light in vacuum; and  $k = 1.3806505 \times 10^{-23}$  J/K is the Boltzmann constant. These data lead to the following values of Planck's first and second constants:  $c_1 = 3.741771 \times 10^{-16}$  W·m<sup>2</sup> and  $c_2 = 1.438775 \times 10^{-2}$  m·K, respectively. Numerical values of the Stephan-Boltzmann constant  $\sigma$  in several systems of units are as follows:  $5.67040 \times 10^{-8}$  W/(m<sup>2</sup>·K<sup>4</sup>);  $1.3544 \times 10^{-12}$  cal/(cm<sup>2</sup>·s·K<sup>4</sup>);  $4.8757 \times 10^{-8}$  kcal/(m<sup>2</sup>·h·K<sup>4</sup>);  $9.9862 \times 10^{-9}$  CHU/(ft<sup>2</sup>·h·K<sup>4</sup>); and  $0.17123 \times 10^{-8}$  Btu/(ft<sup>2</sup>·h·°R<sup>4</sup>) (CHU = centigrade heat unit; 1.0 CHU = 1.8 Btu.)

**Blackbody Displacement Laws** The blackbody energy spectrum

$$\text{is plotted logarithmically in Fig. 5-9 as } \frac{E_{b,\lambda}(\lambda T)}{n^2 T^5} \times 10^{13} \frac{\text{W}}{\text{m}^2 \cdot \mu\text{m} \cdot \text{K}^5}$$

versus  $\lambda T$   $\mu\text{m}\cdot\text{K}$ . For comparison a companion inset is provided in Cartesian coordinates. The upper abscissa of Fig. 5-9 also shows the blackbody energy distribution function  $F_b(\lambda T)$ . Figure 5-9 indicates that the wavelength-temperature product for which the maximum intensity occurs is  $\lambda_{\text{max}} T = 2898 \mu\text{m}\cdot\text{K}$ . This relationship is known as **Wien's displacement law**, which indicates that the wavelength for maximum intensity is *inversely* proportional to the absolute temperature. Blackbody displacement laws are useful in engineering practice to estimate wavelength intervals appropriate to relevant system temperatures. The Wien displacement law can be misleading, however, because the wavelength for maximum intensity depends on whether the intensity is defined in terms of frequency or wavelength interval. Two additional useful displacement laws are defined in terms of either the value of  $\lambda T$  corresponding to the maximum energy per unit *fractional change* in wavelength or frequency, that is,  $\lambda T = 3670 \mu\text{m}\cdot\text{K}$ , or to the value of  $\lambda T$  corresponding to one-half the blackbody energy, that is,  $\lambda T = 4107 \mu\text{m}\cdot\text{K}$ . Approximately one-half of the blackbody energy lies within the twofold  $\lambda T$  range *geometrically centered* on  $\lambda T = 3670 \mu\text{m}\cdot\text{K}$ , that is,  $3670/\sqrt{2} < \lambda T < 3670\sqrt{2}$   $\mu\text{m}\cdot\text{K}$ . Some 95 percent of the blackbody energy lies in the interval  $1662.6 < \lambda T < 16,295 \mu\text{m}\cdot\text{K}$ . It thus follows that for the temperature range between ambient (300 K) and flame temperatures (2000 K or

FIG. 5-9 Spectral dependence of monochromatic blackbody hemispherical emissive power.

3140°F), wavelengths of engineering heat-transfer importance are bounded between 0.83 and 54.3 μm.

**RADIATIVE PROPERTIES OF OPAQUE SURFACES**

**Emittance and Absorptance** The ratio of the total radiating power of any surface to that of a black surface at the same temperature is called the **emittance** or **emissivity**,  $\epsilon$  of the surface.<sup>o</sup> In general, the monochromatic emissivity is a function of temperature, direction, and wavelength, that is,  $\epsilon_\lambda = \epsilon_\lambda(T, \Omega, \lambda)$ . The subscripts  $n$  and  $h$  are sometimes used to denote the normal and hemispherical values, respectively, of the emittance or emissivity. If radiation is incident on a surface, the fraction absorbed is called the **absorptance** (**absorptivity**). Two subscripts are usually appended to the absorptance  $\alpha_{1,2}$  to distinguish between the temperature of the absorbing surface  $T_1$  and the spectral energy distribution of the emitting surface  $T_2$ . According to **Kirchhoff's law**, the emissivity and absorptivity of a surface exposed to surroundings at its own temperature are the same for both monochromatic and total radiation. When the temperatures of the surface and its surroundings differ, the total emissivity and absorptivity of the surface are often found to be unequal; but because the absorptivity is substantially independent of irradiation density, the monochromatic emissivity and absorptivity of surfaces are equal for all practical purposes. The difference between *total* emissivity and absorptivity depends on the variation of  $\epsilon_\lambda$  with wavelength and on the difference between the temperature of the surface and the effective temperature of the surroundings.

Consider radiative exchange between a real surface of area  $A_1$  at temperature  $T_1$  with black surroundings at temperature  $T_2$ . The *net* radiant interchange is given by

$$Q_{1,2} = A_1 \int_{\lambda=0}^{\infty} [\epsilon_\lambda(T_1, \lambda) \cdot E_{b,\lambda}(T_1, \lambda) - \alpha_\lambda(T_1, \lambda) \cdot E_{b,\lambda}(T_2, \lambda)] d\lambda \quad (5-107a)$$

or 
$$Q_{1,2} = A_1 (\epsilon_1 \sigma T_1^4 - \alpha_{1,2} \sigma T_2^4) \quad (5-107b)$$

where 
$$\epsilon_1(T_1) = \int_{\lambda=0}^{\infty} \epsilon_\lambda(T_1, \lambda) \cdot \frac{E_{b,\lambda}(T_1, \lambda)}{E_b(T_1)} d\lambda \quad (5-108)$$

and since 
$$\alpha_\lambda(T, \lambda) = \epsilon_\lambda(T, \lambda),$$

$$\alpha_{1,2}(T_1, T_2) = \int_{\lambda=0}^{\infty} \epsilon_\lambda(T_1, \lambda) \cdot \frac{E_{b,\lambda}(T_2, \lambda)}{E_b(T_2)} d\lambda \quad (5-109)$$

For a *gray surface*  $\epsilon_1 = \alpha_{1,2} = \epsilon_\lambda$ . A *selective surface* is one for which  $\epsilon_\lambda(T, \lambda)$  exhibits a strong dependence on wavelength. If the wavelength dependence is *monotonic*, it follows from Eqs. (5-107) to (5-109) that  $\epsilon_1$  and  $\alpha_{1,2}$  can differ markedly when  $T_1$  and  $T_2$  are widely separated. For example, in solar energy applications, the nominal temperature of the earth is  $T_1 = 294$  K, and the sun may be represented as a blackbody with radiation temperature  $T_2 = 5800$  K. For these temperature conditions, a *white paint* can exhibit  $\epsilon_1 = 0.9$  and  $\alpha_{1,2} = 0.1$  to 0.2. In contrast, a *thin layer of copper oxide on bright aluminum* can exhibit  $\epsilon_1$  as low as 0.12 and  $\alpha_{1,2}$  greater than 0.9.

The effect of radiation source temperature on low-temperature absorptivity for a number of representative materials is shown in Fig. 5-10. Polished aluminum (curve 15) and anodized (surface-oxidized) aluminum (curve 13) are representative of metals and nonmetals, respectively. Figure 5-10 thus demonstrates the generalization that metals and nonmetals respond *in opposite directions* with regard to changes in the radiation source temperature. Since the effective solar temperature is 5800 K (10,440°R), the extreme right-hand side of Fig. 5-10 provides surface absorptivity data relevant to solar energy applications. The dependence of emittance and absorptance on the real and imaginary components of the refractive index and on the geometric

structure of the surface layer is quite complex. However, a number of generalizations concerning the radiative properties of opaque surfaces are possible. These are summarized in the following discussion.

**Polished Metals**

1. In the infrared region, the magnitude of the monochromatic emissivity  $\epsilon_\lambda$  is small and is dependent on free-electron contributions. Emissivity is also a function of the ratio of resistivity to wavelength  $r/\lambda$ , as depicted in Fig. 5-11. At shorter wavelengths, bound-electron contributions become significant,  $\epsilon_\lambda$  is larger in magnitude, and it sometimes exhibits a maximum value. In the visible spectrum, common values for  $\epsilon_\lambda$  are 0.4 to 0.8 and  $\epsilon_\lambda$  decreases slightly as temperature increases. For  $0.7 < \lambda < 1.5$  μm,  $\epsilon_\lambda$  is approximately independent of temperature. For  $\lambda > 8$  μm,  $\epsilon_\lambda$  is approximately proportional to the square root of temperature since  $\epsilon_\lambda \propto \sqrt{r}$  and  $r \propto T$ . Here the Drude or Hagen-Rubens relation applies, that is,  $\epsilon_{\lambda,n} \approx 0.0365 \sqrt{r/\lambda}$ , where  $r$  has units of ohm-meters and  $\lambda$  is measured in micrometers.

2. Total emittance is substantially proportional to absolute temperature, and at moderate temperatures  $\epsilon_n = 0.058T \sqrt{rT}$ , where  $T$  is measured in kelvins.

3. The total absorptance of a metal at temperature  $T_1$  with respect to radiation from a black or gray source at temperature  $T_2$  is equal to the emissivity evaluated at the geometric mean of  $T_1$  and  $T_2$ . Figure 5-11 gives values of  $\epsilon_\lambda$  and  $\epsilon_{\lambda,n}$ , and their ratio, as a function of the product  $rT$  (solid lines). Although Fig. 5-11 is based on free-electron

To convert degrees Rankine to kelvins, multiply by (5.556)(10<sup>-3</sup>).

<sup>o</sup>In the literature, *emittance* and *emissivity* are often used interchangeably. NIST (the National Institute of Standards and Technology) recommends use of the suffix *-ivity* for pure materials with optically smooth surfaces, and *-ance* for rough and contaminated surfaces. Most real engineering materials fall into the latter category.

FIG. 5-11 Hemispherical and normal emissivities of metals and their ratio. Dashed lines: monochromatic (spectral) values versus  $r/\lambda$ . Solid lines: total values versus  $rT$ . To convert ohm-centimeter-kelvins to ohm-meter-kelvins, multiply by  $10^{-2}$ .

contributions to emissivity in the far infrared, the relations for total emissivity are remarkably good even at high temperatures. Unless extraordinary efforts are taken to prevent oxidation, a metallic surface may exhibit an emittance or absorptance which may be several times that of a polished specimen. For example, the emittance of iron and steel depends strongly on the degree of oxidation and roughness. Clean iron and steel surfaces have an emittance from 0.05 to 0.45 at ambient temperatures and 0.4 to 0.7 at high temperatures. Oxidized and/or roughened iron and steel surfaces have values of emittance ranging from 0.6 to 0.95 at low temperatures to 0.9 to 0.95 at high temperatures.

**Refractory Materials** For refractory materials, the dependence of emittance and absorptance on grain size and impurity concentrations is quite important.

1. Most refractory materials are characterized by  $0.8 < \epsilon_\lambda < 1.0$  for the wavelength region  $2 < \lambda < 4 \mu\text{m}$ . The monochromatic emissivity  $\epsilon_\lambda$  decreases rapidly toward shorter wavelengths for materials that are white in the visible range but demonstrates high values for black materials such as  $\text{FeO}$  and  $\text{Cr}_2\text{O}_3$ . Small concentrations of  $\text{FeO}$  and  $\text{Cr}_2\text{O}_3$  or other colored oxides, can cause marked increases in the emittance of materials that are normally white. The sensitivity of the emittance of refractory oxides to small additions of absorbing materials is demonstrated by the results of calculations presented in Fig. 5-12. Figure 5-12 shows the emittance of a semi-infinite absorbing-scattering medium as a function of its albedo  $\omega \equiv K_s/(K_a + K_s)$ , where  $K_a$  and  $K_s$  are the scatter and absorption coefficients, respectively. These results are relevant to the radiative properties of fibrous materials, paints, oxide coatings, refractory materials, and other particulate media. They demonstrate that over the relatively small range  $1 - \omega = 0.005$  to  $0.1$ , the hemispherical emittance  $\epsilon_h$  increases from approximately 0.15 to 1.0. For refractory materials,  $\epsilon_\lambda$  varies little with temperature, with the exception of some white oxides which at high temperatures become good emitters in the visible spectrum as a consequence of the induced electronic transitions.

2. For refractory materials at ambient temperatures, the total emittance  $\epsilon$  is generally high (0.7 to 1.0). Total refractory emittance decreases with increasing temperature, such that a temperature increase from 1000 to 1570°C may result in a 20 to 30 percent reduction in  $\epsilon$ .

3. Emittance and absorptance increase with increase in grain size over a grain size range of 1 to 200  $\mu\text{m}$ .

4. The ratio  $\epsilon_h/\epsilon_n$  of hemispherical to normal emissivity of polished surfaces varies with refractive index  $n$ ; e.g., the ratio decreases from a value of 1.0 when  $n = 1.0$  to a value of 0.93 when  $n = 1.5$  (common glass) and increases back to 0.96 at  $n = 3.0$ .

5. As shown in Fig. 5-12, for a surface composed of particulate

FIG. 5-12 Hemispherical emittance  $\epsilon_h$  and the ratio of hemispherical to normal emittance  $\epsilon_h/\epsilon_n$  for a semi-infinite absorbing-scattering medium.

matter which scatters isotropically, the ratio  $\epsilon_h/\epsilon_n$  varies from 1.0 when  $\omega < 0.1$  to about 0.8 when  $\omega = 0.999$ .

6. The total absorptance exhibits a decrease with an increase in temperature of the radiation source similar to the decrease in emittance with an increase in the emitter temperature.

Figure 5-10 shows a regular variation of  $\alpha_{1,2}$  with  $T_2$ . When  $T_2$  is not very different from  $T_1$ ,  $\alpha_{1,2} = \epsilon_1(T_2/T_1)^m$ . It may be shown that Eq. (5-107b) is then approximated by

$$Q_{1,2} = (1 + m/4)\epsilon_{av} A_1 \sigma(T_1^4 - T_2^4) \quad (5-110)$$

where  $\epsilon_{av}$  is evaluated at the arithmetic mean of  $T_1$  and  $T_2$ . For metals  $m \approx 0.5$  while for nonmetals  $m$  is small and negative.

Table 5-4 illustrates values of emittance for materials encountered in engineering practice. It is based on a critical evaluation of early emissivity data. Table 5-4 demonstrates the wide variation possible in the emissivity of a particular material due to variations in surface roughness and thermal pretreatment. With few exceptions the data in Table 5-4 refer to emittances  $\epsilon_n$  normal to the surface. The hemispherical emittance  $\epsilon_h$  is usually slightly smaller, as demonstrated by the ratio  $\epsilon_h/\epsilon_n$  depicted in Fig. 5-12. More recent data support the range of emittance values given in Table 5-4 and their dependence on surface conditions. An extensive compilation is provided by Goldsmith, Waterman, and Hirschorn (*Thermophysical Properties of Matter*, Purdue University, Touloukian, ed., Plenum, 1970-1979).

For opaque materials the reflectance  $\rho$  is the complement of the absorptance. The directional distribution of the reflected radiation depends on the material, its degree of roughness or grain size, and, if a metal, its state of oxidation. Polished surfaces of homogeneous materials are specular reflectors. In contrast, the intensity of the radiation reflected from a perfectly diffuse or Lambert surface is independent of direction. The directional distribution of reflectance of many oxidized metals, refractory materials, and natural products approximates that of a perfectly diffuse reflector. A better model, adequate for many calculation purposes, is achieved by assuming that the total reflectance is the sum of diffuse and specular components  $\rho_D$  and  $\rho_S$ , as discussed in a subsequent section.

**VIEW FACTORS AND DIRECT EXCHANGE AREAS**

Consider radiative interchange between two finite black surface area elements  $A_1$  and  $A_2$  separated by a transparent medium. Since they are black, the surfaces emit isotropically and totally absorb all incident radiant energy. It is desired to compute the fraction of radiant energy, per unit emissive power  $E_1$ , leaving  $A_1$  in all directions which is intercepted and absorbed by  $A_2$ . The required quantity is defined as the **direct view factor** and is assigned the notation  $F_{1,2}$ . Since the net radiant energy interchange  $Q_{1,2} \equiv A_1 F_{1,2} E_1 - A_2 F_{2,1} E_2$  between surfaces  $A_1$  and  $A_2$  must be zero when their temperatures are equal, it follows

TABLE 5-4 Normal Total Emissivity of Various Surfaces

\*When two temperatures and two emissivities are given, they correspond, first to first and second to second, and linear interpolation is permissible. °C = (°F – 32)/1.8.

†Although this value is probably high, it is given for comparison with the data by the same investigator to show the effect of oil layers. See Aluminum, Part A of this table.

thermodynamically that  $A_1F_{1,2} = A_2F_{2,1}$ . The product of area and view factor  $\overline{s_i s_j} \equiv A_i F_{i,j}$ , which has the dimensions of area, is termed the **direct surface-to-surface exchange area** for finite black surfaces. Clearly, direct exchange areas are symmetric with respect to their subscripts, that is,  $\overline{s_i s_j} = \overline{s_j s_i}$ , but view factors are not symmetric unless the associated surface areas are equal. This property is referred to as the **symmetry or reciprocity relation** for direct exchange areas. The shorthand notation  $\overline{s_i s_j} \equiv 12 = 21$  for direct exchange areas is often found useful in mathematical developments.

Equation (5-101) may also be restated as

$$\frac{\partial^2 \overline{s_i s_j}}{\partial A_i \partial A_j} = \frac{\cos \phi_i \cos \phi_j}{\pi r^2} \quad (5-111)$$

which leads directly to the required definition of the direct exchange area as a double surface integral

$$\overline{s_i s_j} = \iint_{A_i} \iint_{A_j} \frac{\cos \phi_i \cos \phi_j}{\pi r^2} dA_j dA_i \quad (5-112)$$

All terms in Eq. (5-112) have been previously defined.

Suppose now that Eq. (5-112) is integrated over the entire confining surface of an **enclosure** which has been subdivided into *M* finite area elements. Each of the *M* surface **zones** must then satisfy certain **conservation relations** involving *all* the direct exchange areas in the enclosure

$$\sum_{j=1}^M \overline{s_i s_j} = A_i \quad \text{for } 1 \leq i \leq M \quad (5-113a)$$

or in terms of view factors

$$\sum_{j=1}^M F_{ij} = 1 \quad \text{for } 1 \leq i \leq M \quad (5-113b)$$

**Contour integration** is commonly used to simplify the evaluation of Eq. (5-112) for specific geometries; see Modest (op. cit., Chap. 4)

or Siegel and Howell (op. cit., Chap. 5). The formulas for two particularly useful view factors involving perpendicular rectangles of area *xz* and *yz* with common edge *z* and equal parallel rectangles of area *xy* and distance of separation *z* are given for **perpendicular rectangles** with common dimension *z*

$$\begin{aligned} (\pi \cdot X) \cdot F_{XY} &= X \tan^{-1} \frac{1}{X} + Y \tan^{-1} \frac{1}{Y} - \sqrt{X^2 + Y^2} \tan^{-1} \sqrt{\frac{1}{X^2 + Y^2}} \\ &+ \frac{1}{4} \ln \left\{ \frac{(1 + X^2)(1 + Y^2)}{1 + X^2 + Y^2} \left[ \frac{X^2(1 + X^2 + Y^2)}{(1 + X^2)(X^2 + Y^2)} \right]^{X^2} \left[ \frac{Y^2(1 + X^2 + Y^2)}{(1 + Y^2)(X^2 + Y^2)} \right]^{Y^2} \right\} \end{aligned} \quad (5-114a)$$

and for **parallel rectangles**, separated by distance *z*,

$$\begin{aligned} \left( \frac{\pi \cdot X \cdot Y}{2} \right) \cdot F_{XY} &= \ln \left[ \frac{(1 + X^2)(1 + Y^2)}{1 + X^2 + Y^2} \right]^{1/2} + X \sqrt{1 + Y^2} \tan^{-1} \frac{X}{\sqrt{1 + Y^2}} \\ &+ Y \sqrt{1 + X^2} \tan^{-1} \frac{Y}{\sqrt{1 + X^2}} - X \tan^{-1} X - Y \tan^{-1} Y \end{aligned} \quad (5-114b)$$

In Eqs. (5-114) *X* and *Y* are normalized whereby  $X = x/z$  and  $Y = y/z$  and the corresponding **dimensional** direct surface areas are given by  $\overline{s_i s_j} = xz F_{XY}$  and  $\overline{s_i s_j} = xy F_{XY}$ , respectively.

The exchange area between any two area elements of a sphere is independent of their relative shape and position and is simply the product of the areas, divided by the area of the entire sphere; i.e., any spot on a sphere has equal views of all other spots.

Figure 5-13, curves 1 through 4, shows view factors for selected parallel opposed disks, squares, and 2:1 rectangles and parallel rectangles with one infinite dimension as a function of the ratio of the

FIG. 5-13 Radiation between parallel planes, directly opposed.

smaller diameter or side to the distance of separation. Curves 2 through 4 of Fig. 5-13, for opposed rectangles, can be computed with Eq. (5-114b). The view factors for two finite coaxial coextensive cylinders of radii  $r \leq R$  and height  $L$  are shown in Fig. 5-14. The direct view factors for an infinite plane parallel to a system of rows of parallel tubes (see Fig. 5-16) are given as curves 1 and 3 of Fig. 5-15. The view factors for this two-dimensional geometry can be readily calculated by using the **crossed-strings method**.

The crossed-strings method, due to Hottel (*Radiative Transfer*, McGraw-Hill, New York, 1967), is stated as follows: "The exchange area for two-dimensional surfaces,  $A_1$  and  $A_2$ , per unit length (in the infinite dimension) is given by the sum of the lengths of crossed strings from the ends of  $A_1$  to the ends of  $A_2$  less the sum of the uncrossed strings from and to the same points all divided by 2." The strings must be drawn so that all the flux from one surface to the other must cross each of a pair of crossed strings and neither of the pair of uncrossed strings. If one surface can see the other around both sides of an obstruction, two more pairs of strings are involved. The calculation procedure is demonstrated by evaluation of the tube-to-tube view factor for one row of a tube bank, as illustrated in Example 7.

**Example 7: The Crossed-Strings Method** Figure 5-16 depicts the transverse cross section of two infinitely long, parallel circular tubes of diameter  $D$  and center-to-center distance of separation  $C$ . Use the crossed-strings method to formulate the tube-to-tube direct exchange area and view factor  $s_i s_j$  and  $F_{i,j}$ , respectively.

**Solution:** The circumferential area of each tube is  $A_i = \pi D$  per unit length in the infinite dimension for this two-dimensional geometry. Application of the crossed-strings procedure then yields simply

FIG. 5-15 Distribution of radiation to rows of tubes irradiated from one side. Dashed lines: direct view factor  $F$  from plane to tubes. Solid lines: total view factor  $F$  for black tubes backed by a refractory surface.

$$\overline{s_i s_j} = \frac{2(EFGH - HJ)}{2} = D[\sin^{-1}(1/R) + \sqrt{R^2 - 1} - R]$$

and

$$F_{i,j} = \overline{s_i s_j} / A_i = [\sin^{-1}(1/R) + \sqrt{R^2 - 1} - R] \pi$$

where  $EFGH$  and  $HJ = C$  are the indicated line segments and  $R \equiv C/D \geq 1$ . Curve 1 of Fig. 5-15, denoted by  $F_{p,t}$ , is a function of  $F_{i,j}$ , that is,  $F_{p,t} = (\pi/R)(\frac{1}{2} - F_{i,j})$ .

The **Yamauti principle** [Yamauti, *Res. Electrotech Lab. (Tokyo)*, 148 (1924); 194 (1927); 250 (1929)] is stated as follows: *The exchange areas between two pairs of surfaces are equal when there is a one-to-one correspondence for all sets of symmetrically positioned pairs of differential elements in the two surface combinations.* Figure 5-17 illustrates the Yamauti principle applied to surfaces in perpendicular planes having a common edge. With reference to Fig. 5-17, the Yamauti principle states that the diagonally opposed exchange areas are equal, that is,  $(1)(4) = (2)(3)$ . Figure 5-17 also shows a more complex geometric construction for displaced cylinders for which the Yamauti principle also applies. Collectively the three terms *reciprocity* or *symmetry principle*, *conservation*

FIG. 5-14 View factors for a system of two concentric coaxial cylinders of equal length. (a) Inner surface of outer cylinder to inner cylinder. (b) Inner surface of outer cylinder to itself.

FIG. 5-16 Direct exchange between parallel circular tubes.

principle, and Yamauti principle are referred to as **view factor or exchange area algebra**.

**Example 8: Illustration of Exchange Area Algebra** Figure 5-17 shows a graphical construction depicting four perpendicular opposed rectangles with a common edge. Numerically evaluate the direct exchange areas and view factors for the diagonally opposed (shaded) rectangles  $A_1$  and  $A_4$ , that is,  $\overline{(1)(4)}$ , as well as  $\overline{(1)(3+4)}$ . The dimensions of the rectangular construction are shown in Fig. 5-17 as  $x=3$ ,  $y=2$ , and  $z=1$ .

**Solution:** Using shorthand notation for direct exchange areas, the conservation principle yields

$$\overline{(1+2)(3+4)} = \overline{(1+2)(3)} + \overline{(1+2)(4)} = \overline{(1)(3)} + \overline{(2)(3)} + \overline{(1)(4)} + \overline{(2)(4)}$$

Now by the Yamauti principle we have  $\overline{(1)(4)} \equiv \overline{(2)(3)}$ . Combination of these two relations yields the first result  $\overline{(1)(4)} = [\overline{(1+2)(3+4)} - \overline{(1)(3)} - \overline{(2)(4)}] / 2$ . For  $\overline{(1)(3+4)}$ , again conservation yields  $\overline{(1)(3+4)} = \overline{(1)(3)} + \overline{(1)(4)}$ , and substitution of the expression for  $\overline{(1)(4)}$  just obtained yields the second result, that is,  $\overline{(1)(3+4)} = [\overline{(1+2)(3+4)} + \overline{(1)(3)} - \overline{(2)(4)}] / 2.0$ . All three required direct exchange areas in these two relations are readily evaluated from Eq. (5-114a). Moreover, these equations apply to opposed parallel rectangles as well as rectangles with a common edge oriented at any angle. Numerically it follows from Eq. (5-114a) that for  $X = \frac{1}{3}$ ,  $Y = \frac{2}{3}$ , and  $z = 3$  that  $\overline{(1+2)(3+4)} = 0.95990$ ; for  $X = 1$ ,  $Y = 2$ , and  $z = 1$  that  $\overline{(1)(3)} = 0.23285$ ; and for  $X = \frac{1}{2}$ ,  $Y = 1$ , and  $z = 2$  that  $\overline{(2)(4)} = 0.585747$ . Since  $A_1 = 1.0$ , this leads to  $s_{134} = F_{1,3+4} = (0.95990 - 0.23285 - 0.584747) / 2.0 = 0.07115$  and  $s_{13+4} = F_{1,3+4} = (0.95990 + 0.23285 - 0.584747) / 2.0 = 0.30400$ .

Many literature sources document closed-form algebraic expressions for view factors. Particularly comprehensive references include the compendia by Modest (op. cit., App. D) and Siegel and Howell (op. cit., App. C). The appendices for both of these textbooks also provide a wealth of resource information for radiative transfer. Appendix F of Modest, e.g., references an extensive listing of Fortran computer codes for a variety of radiation calculations which include view factors. These codes are archived in the dedicated Internet web site maintained by the publisher. The textbook by Siegel and Howell also includes an extensive database of view factors archived on a CD-ROM and includes a reference to an author-maintained Internet web site. Other historical sources for view factors include Hottel and Sarofim (op. cit., Chap. 2) and Hamilton and Morgan (NACA-TN 2836, December 1952).

**RADIATIVE EXCHANGE IN ENCLOSURES—THE ZONE METHOD**

**Total Exchange Areas** When an enclosure contains reflective surface zones, allowance must be made for not only the radiant energy transferred directly between any two zones but also the additional transfer attendant to however many multiple reflections which occur among the intervening reflective surfaces. Under such circumstances,

FIG. 5-17 Illustration of the Yamauti principle.

it can be shown that the net radiative flux  $Q_{ij}$  between all such surface zone pairs  $A_i$  and  $A_j$ , making full allowance for all multiple reflections, may be computed from

$$Q_{ij} = \sigma(A_i \mathcal{F}_{ij} T_j^4 - A_j \mathcal{F}_{ji} T_i^4) \tag{5-115}$$

Here,  $\mathcal{F}_{ij}$  is defined as the **total surface-to-surface view factor** from  $A_i$  to  $A_j$ , and the quantity  $S_i S_j \equiv A_i \mathcal{F}_{ij}$  is defined as the corresponding **total surface-to-surface exchange area**. In analogy with the direct exchange areas, the total surface-to-surface exchange areas are also symmetric and thus obey reciprocity, that is,  $A_i \mathcal{F}_{ij} = A_j \mathcal{F}_{ji}$  or  $S_i S_j = S_j S_i$ . When applied to an enclosure, total exchange areas and view factors also must satisfy appropriate conservation relations. Total exchange areas are functions of the geometry and radiative properties of the entire enclosure. They are also independent of temperature if all surfaces and any radiatively participating media are gray. The following subsection presents a general matrix method for the explicit evaluation of total exchange areas from direct exchange areas and other enclosure parameters.

In what follows, conventional matrix notation is strictly employed as in  $\mathbf{A} = [a_{ij}]$  wherein the scalar subscripts always denote the row and column indices, respectively, and all matrix entities defined here are denoted by boldface notation. Section 3 of this handbook, "Mathematics," provides an especially convenient reference for introductory matrix algebra and matrix computations.

**General Matrix Formulation** The zone method is perhaps the simplest numerical quadrature of the governing integral equations for radiative transfer. It may be derived from first principles by starting with the equation of transfer for radiation intensity. The zone method always conserves radiant energy since the spatial discretization utilizes macroscopic energy balances involving spatially averaged radiative flux quantities. Because large sets of linear algebraic equations can arise in this process, matrix algebra provides the most compact notation and the most expeditious methods of solution. The mathematical approach presented here is a matrix generalization of the original (scalar) development of the zone method due to Hottel and Sarofim (op. cit.). The present matrix development is abstracted from that introduced by Noble [Noble, J. J., Int. J. Heat Mass Transfer, 18, 261–269 (1975)].

Consider an arbitrary three-dimensional enclosure of total volume  $V$  and surface area  $A$  which confines an absorbing-emitting medium (gas). Let the enclosure be subdivided (zoned) into  $M$  finite surface area and  $N$  finite volume elements, each small enough that all such zones are substantially isothermal. The mathematical development in this section is restricted by the following conditions and/or assumptions:

1. The gas temperatures are given a priori.
2. Allowance is made for gas-to-surface radiative transfer.
3. Radiative transfer with respect to the confined gas is either monochromatic or gray. The gray gas absorption coefficient is denoted here by  $K(m^{-1})$ . In subsequent sections the monochromatic absorption coefficient is denoted by  $K_r(\lambda)$ .
4. All surface emissivities are assumed to be gray and thus independent of temperature.
5. Surface emission and reflection are isotropic or diffuse.
6. The gas does not scatter.

Noble (op. cit.) has extended the present matrix methodology to the case where the gaseous absorbing-emitting medium also scatters isotropically.

In matrix notation the blackbody emissive powers for all surface and volume zones comprising the zoned enclosure are designated as  $\mathbf{E} = [E_i]$ , an  $M \times 1$  vector, and  $\mathbf{E}_g = [E_{g,i}] = [\sigma T_{g,i}^4]$ , an  $N \times 1$  vector, respectively. Moreover, all surface zones are characterized by three  $M \times M$  diagonal matrices for zone area  $\mathbf{A} \mathbf{I} = [A_i \delta_{ij}]$ , diffuse emissivity  $\mathbf{e} \mathbf{I} = [e_i \delta_{ij}]$ , and diffuse reflectivity,  $\rho \mathbf{I} = [(1 - e_i) \delta_{ij}]$ , respectively. Here  $\delta_{ij}$  is the **Kronecker delta** (that is,  $\delta_{ij} = 1$  for  $i = j$  and  $\delta_{ij} = 0$  for  $i \neq j$ ).

Two arrays of direct exchange areas are now defined; i.e., the matrix  $\overline{\mathbf{ss}} = [\overline{s_i s_j}]$  is the  $M \times M$  array of **direct surface-to-surface exchange areas**, and the matrix  $\overline{\mathbf{sg}} = [\overline{s_i g_j}]$  is the  $M \times N$  array of **direct gas-to-surface exchange areas**. Here the scalar elements of  $\overline{\mathbf{ss}}$  and  $\overline{\mathbf{sg}}$  are computed from the integrals

$$\overline{s_i s_j} = \iiint_{A_i} \iiint_{A_j} \frac{e^{-Kr}}{\pi r^2} \cos \phi_i \cos \phi_j dA_i dA_j \tag{5-116a}$$

$$\overline{s_i g_j} = \iint_{A_i} \iint_{V_j} K \frac{e^{-Kr}}{\pi r^2} \cos \phi_i dV_j dA_i \quad (5-116b)$$

Equation (5-116a) is a generalization of Eq. (5-112) for the case  $K \neq 0$  while  $\overline{s_i g_j}$  is a new quantity, which arises *only* for the case  $K \neq 0$ .

Matrix characterization of the radiative energy balance at each surface zone is facilitated via definition of three  $M \times 1$  vectors; the radiative surface fluxes  $\mathbf{Q} = [Q_i]$ , with units of watts; and the vectors  $\mathbf{H} = [H_i]$  and  $\mathbf{W} = [W_i]$  both having units of  $\text{W}/\text{m}^2$ . The arrays  $\mathbf{H}$  and  $\mathbf{W}$  define the *incident* and *leaving* flux densities, respectively, at each surface zone. The variable  $\mathbf{W}$  is also referred to in the literature as the **radiosity** or **exitance**. Since  $\mathbf{W} \equiv \epsilon \mathbf{I} \cdot \mathbf{E} + \rho \mathbf{I} \cdot \mathbf{H}$ , the radiative flux at each surface zone is also defined in terms of  $\mathbf{E}$ ,  $\mathbf{H}$ , and  $\mathbf{W}$  by three equivalent matrix relations, namely,

$$\mathbf{Q} = \mathbf{AI} \cdot [\mathbf{W} - \mathbf{H}] = \epsilon \mathbf{AI} \cdot [\mathbf{E} - \mathbf{H}] = \rho \mathbf{I}^{-1} \cdot \epsilon \mathbf{AI} \cdot [\mathbf{E} - \mathbf{W}] \quad (5-117)$$

where the third form is valid *if and only if the matrix inverse*  $\rho \mathbf{I}^{-1}$  *exists*. Two other ancillary matrix expressions are

$$\epsilon \mathbf{AI} \cdot \mathbf{E} = \rho \mathbf{I} \cdot \mathbf{Q} + \epsilon \mathbf{AI} \cdot \mathbf{W} \quad \text{and} \quad \mathbf{AI} \cdot \mathbf{H} = \overline{\mathbf{SS}} \cdot \mathbf{W} + \overline{\mathbf{SG}} \cdot \mathbf{E}_g \quad (5-117a,b)$$

which lead to

$$\epsilon \mathbf{I} \cdot \mathbf{E} = [\mathbf{I} - \rho \mathbf{I} \cdot \mathbf{AI}^{-1} \cdot \overline{\mathbf{SS}}] \cdot \mathbf{W} - \rho \mathbf{I} \cdot \mathbf{AI}^{-1} \cdot \overline{\mathbf{SG}} \cdot \mathbf{E}_g \quad (5-117c)$$

The latter relation is especially useful in radiation pyrometry where true wall temperatures must be computed from wall radiosities.

**Explicit Matrix Solution for Total Exchange Areas** For gray or monochromatic transfer, the **primary working relation** for zoning calculations via the matrix method is

$$\mathbf{Q} = \epsilon \mathbf{I} \cdot \mathbf{AI} \cdot \mathbf{E} - \overline{\mathbf{SS}} \cdot \mathbf{E} - \overline{\mathbf{SG}} \cdot \mathbf{E}_g \quad [M \times 1] \quad (5-118)$$

Equation (5-118) makes full allowance for multiple reflections in an enclosure of any degree of complexity. To apply Eq. (5-118) for design or simulation purposes, the gas temperatures must be known and surface boundary conditions must be specified for each and every surface zone in the form of *either*  $E_i$  or  $Q_i$ . In application of Eq. (5-118), *physically impossible values* of  $E_i$  may well result if *physically unrealistic values* of  $Q_i$  are specified.

In Eq. (5-118),  $\overline{\mathbf{SS}}$  and  $\overline{\mathbf{SG}}$  are defined as the *required* arrays of **total surface-to-surface exchange areas** and **total gas-to-surface exchange areas**, respectively. The matrices for total exchange areas are calculated *explicitly* from the corresponding arrays of direct exchange areas and the other enclosure parameters by the following matrix formulas:

$$\text{Surface-to-surface exchange} \quad \overline{\mathbf{SS}} = \epsilon \mathbf{I} \cdot \mathbf{AI} \cdot \mathbf{R} \cdot \overline{\mathbf{SS}} \cdot \epsilon \mathbf{I} \quad [M \times M] \quad (5-118a)$$

$$\text{Gas-to-surface exchange} \quad \overline{\mathbf{SG}} = \epsilon \mathbf{I} \cdot \mathbf{AI} \cdot \mathbf{R} \cdot \overline{\mathbf{SG}} \quad [M \times N] \quad (5-118b)$$

where in Eqs. (5-118),  $\mathbf{R}$  is the explicit **inverse reflectivity matrix**, defined as

$$\mathbf{R} = [\mathbf{AI} - \overline{\mathbf{SS}} \cdot \rho \mathbf{I}]^{-1} \quad [M \times M] \quad (5-118c)$$

While the  $\mathbf{R}$  matrix is generally not symmetric, the matrix product  $\rho \mathbf{I} \cdot \mathbf{R}$  is *always* symmetric. This fact proves useful for error checking.

The most computationally significant aspect of the matrix method is that the inverse reflectivity matrix  $\mathbf{R}$  *always exists* for any physically meaningful enclosure problem. More precisely,  $\mathbf{R}$  always exists provided that  $K \neq 0$ . For a transparent medium,  $\mathbf{R}$  exists provided that there *formally* exists at least one surface zone  $A_i$  such that  $\epsilon_i \neq 0$ . An important computational corollary of this statement for *transparent media* is that the matrix  $[\mathbf{AI} - \overline{\mathbf{SS}}]$  is *always singular* and demonstrates *matrix rank*  $M - 1$  (Noble, op. cit.).

Finally, the four matrix arrays  $\overline{\mathbf{SS}}$ ,  $\overline{\mathbf{GS}}$ ,  $\overline{\mathbf{SS}}$ , and  $\overline{\mathbf{SG}}$  of direct and total exchange areas must satisfy **matrix conservation relations**, i.e.,

$$\text{Direct exchange areas} \quad \mathbf{AI} \cdot \mathbf{I}_M = \overline{\mathbf{SS}} \cdot \mathbf{I}_M + \overline{\mathbf{SG}} \cdot \mathbf{I}_N \quad (5-119a)$$

$$\text{Total exchange areas} \quad \epsilon \mathbf{I} \cdot \mathbf{AI} \cdot \mathbf{I}_M = \overline{\mathbf{SS}} \cdot \mathbf{I}_M + \overline{\mathbf{SG}} \cdot \mathbf{I}_N \quad (5-119b)$$

Here  $\mathbf{I}_M$  is an  $M \times 1$  column vector all of whose elements are unity. If  $\epsilon \mathbf{I} = \mathbf{I}$  or equivalently,  $\rho \mathbf{I} = \mathbf{0}$ , Eq. (5-118c) reduces to  $\mathbf{R} = \mathbf{AI}^{-1}$  with

the result that Eqs. (5-118a) and (5-118b) degenerate to simply  $\overline{\mathbf{SS}} = \overline{\mathbf{SS}}$  and  $\overline{\mathbf{SG}} = \overline{\mathbf{SG}}$ . Further, while the array  $\overline{\mathbf{SS}}$  is always symmetric, the array  $\overline{\mathbf{SG}}$  is generally not square.

For purposes of digital computation, it is good practice to enter all data for direct exchange surface-to-surface areas  $\overline{\mathbf{SS}}$  with a precision of *at least five significant figures*. This need arises because all the scalar elements of  $\overline{\mathbf{SG}}$  can be calculated *arithmetically* from appropriate direct surface-to-surface exchange areas by using view factor algebra rather than via the definition of the defining integral, Eq. (5-116b). This process often involves small arithmetic differences between two numbers of nearly equal magnitude, and numerical significance is easily lost.

Computer implementation of the matrix method proves straightforward, given the availability of modern software applications. In particular, several especially user-friendly GUI mathematical utilities are available that perform matrix computations using *essentially algebraic notation*. Many simple zoning problems may be solved with spreadsheets. For large  $M$  and  $N$ , the matrix method can involve management of a large amount of data. Error checks based on symmetry and conservation by calculation of the row sums of the four arrays of direct and total exchange areas then prove indispensable.

**Zone Methodology and Conventions** For a transparent medium, no more than  $\Sigma = M(M - 1)/2$  of the  $M^2$  elements of the  $\overline{\mathbf{SS}}$  array are *unique*. Further, surface zones are characterized into two generic types. **Source-sink zones** are defined as those for which temperature is specified and whose radiative flux  $Q_i$  is to be determined. For **flux zones**, conversely, these conditions are reversed. When both types of zones are present in an enclosure, Eq. (5-118) may be *partitioned* to produce a more efficient computational algorithm. Let  $M = M_s + M_f$  represent the total number of surface zones where  $M_s$  is the number of source-sink zones and  $M_f$  is the number of flux zones. The flux zones are the *last to be numbered*. Equation (5-118) is then partitioned as follows:

$$\begin{bmatrix} \mathbf{Q}_1 \\ \mathbf{Q}_2 \end{bmatrix} = \begin{bmatrix} \epsilon \mathbf{AI}_{1,1} & \mathbf{0} \\ \mathbf{0} & \epsilon \mathbf{AI}_{2,2} \end{bmatrix} \cdot \begin{bmatrix} \mathbf{E}_1 \\ \mathbf{E}_2 \end{bmatrix} - \begin{bmatrix} \overline{\mathbf{SS}}_{1,1} & \overline{\mathbf{SS}}_{1,2} \\ \overline{\mathbf{SS}}_{2,1} & \overline{\mathbf{SS}}_{2,2} \end{bmatrix} \cdot \begin{bmatrix} \mathbf{E}_1 \\ \mathbf{E}_2 \end{bmatrix} - \begin{bmatrix} \overline{\mathbf{SG}}_1 \\ \overline{\mathbf{SG}}_2 \end{bmatrix} \cdot \mathbf{E}_g \quad (5-120)$$

Here the dimensions of the submatrices  $\epsilon \mathbf{AI}_{1,1}$  and  $\overline{\mathbf{SS}}_{1,1}$  are both  $M_s \times M_s$  and  $\overline{\mathbf{SG}}_1$  has dimensions  $M_s \times N$ . Partition algebra then yields the following two matrix equations for  $\mathbf{Q}_1$ , the  $M_s \times 1$  vector of unknown source-sink fluxes and  $\mathbf{E}_2$ , the  $M_f \times 1$  vector of unknown emissive powers for the flux zones, i.e.,

$$\mathbf{E}_2 = [\epsilon \mathbf{AI}_{2,2} - \overline{\mathbf{SS}}_{2,2}]^{-1} \cdot [\mathbf{Q}_2 + \overline{\mathbf{SS}}_{2,1} \cdot \mathbf{E}_1 + \overline{\mathbf{SG}}_2 \cdot \mathbf{E}_g] \quad (5-120a)$$

$$\mathbf{Q}_1 = \epsilon \mathbf{AI}_{1,1} \cdot \mathbf{E}_1 - \overline{\mathbf{SS}}_{1,1} \cdot \mathbf{E}_1 - \overline{\mathbf{SS}}_{1,2} \cdot \mathbf{E}_2 - \overline{\mathbf{SG}}_1 \cdot \mathbf{E}_g \quad (5-120b)$$

The inverse matrix in Eq. (5-120a) formally does not exist if there is at least one flux zone such that  $\epsilon_i = 0$ . However, well-behaved results are usually obtained with Eq. (5-120a) by utilizing a *notional zero*, say,  $\epsilon_i \approx 10^{-5}$ , to simulate  $\epsilon_i = 0$ . Computationally,  $\mathbf{E}_2$  is first obtained from Eq. (5-120a) and then substituted into either Eq. (5-120b) or Eq. (5-118).

Surface zones need not be *contiguous*. For example, in a symmetric enclosure, zones on opposite sides of the plane of symmetry may be "lumped" into a single zone for computational purposes. Lumping nonsymmetrical zones is also possible as long as the zone temperatures and emissivities are equal.

An **adiabatic refractory surface** of area  $A_i$  and emissivity  $\epsilon_r$ , for which  $Q_r = 0$ , proves quite important in practice. A nearly radiatively adiabatic refractory surface occurs when differences between internal conduction and convection and external heat losses through the refractory wall are small compared with the *magnitude* of the *incident* and *leaving* radiation fluxes. For *any* surface zone, the radiant flux is given by  $Q = A(W - H) = \epsilon A(E - H)$  and  $Q = \epsilon A/\rho(E - W)$  (if  $\rho \neq 0$ ). These equations then lead to the result that if  $Q_r = 0$ ,  $E_r = H_r = W_r$ , for all  $0 \leq \epsilon_r \leq 1$ . *Sufficient conditions* for modeling an adiabatic refractory zone are thus *either* to put  $\epsilon_r = 0$  or to specify *directly* that  $Q_r = 0$  with  $\epsilon_r \neq 0$ . If  $\epsilon_r = 0$ ,  $S_r S_j = 0$  for all  $1 \leq j \leq M$  which leads *directly by definition* to  $Q_r = 0$ . For  $\epsilon_r = 0$ , the refractory emissive power  $E_r$  *never enters the zoning calculations*. For the special case of  $K = 0$  and  $M_r = 1$ , a single (lumped) refractory, with  $Q_r = 0$  and  $\epsilon_r \neq 0$ ,  $S_r S_j \neq 0$  and the refractory emissive power may be calculated from Eq. (5-120a) as a weighted sum of all *other known blackbody emissive powers* which

characterize the enclosure, i.e.,

$$E_r = \frac{\sum_{j=1}^{M_s} \overline{S_r S_j} E_j}{\sum_{j=1}^{M_s} \overline{S_r S_j}} \quad \text{with } j \neq r \quad (5-121)$$

Equation (5-121) specifically includes those zones which may not have a direct view of the refractory. When  $Q_r = 0$ , the refractory surface is said to be in **radiative equilibrium** with the entire enclosure. Equation (5-121) is indeterminate if  $\epsilon_r = 0$ . If  $\epsilon_r = 0$ ,  $E_r$  does indeed exist and may be evaluated with use of the statement  $E_r = H_r = W_r$ . It transpires, however, that  $E_r$  is independent of  $\epsilon_r$  for all  $0 \leq \epsilon_r \leq 1$ . Moreover, since  $W_r = H_r$  when  $Q_r = 0$ , for all  $0 \leq \epsilon_r \leq 1$ , the value specified for  $\epsilon_r$  is irrelevant to radiative transfer in the entire enclosure. In particular it follows that if  $Q_r = 0$ , then the vectors  $\mathbf{W}$ ,  $\mathbf{H}$ , and  $\mathbf{Q}$  for the entire enclosure are also independent of all  $0 \leq \epsilon_r \leq 1.0$ . A surface zone for which  $\epsilon_i = 0$  is termed a **perfect diffuse mirror**. A perfect diffuse mirror is thus also an adiabatic surface zone. The matrix method automatically deals with all options for flux and adiabatic refractory surfaces.

**The Limiting Case of a Transparent Medium** For the special case of a transparent medium,  $K = 0$ , many practical engineering applications can be modeled with the zone method. These include combustion-fired muffle furnaces and electrical resistance furnaces. When  $K \rightarrow 0$ ,  $\overline{\mathbf{sg}} \rightarrow \mathbf{0}$  and  $\overline{\mathbf{SG}} \rightarrow \mathbf{0}$ . Equations (5-118) through (5-119) then reduce to three simple matrix relations

$$\mathbf{Q} = \epsilon \mathbf{I} \mathbf{A} \mathbf{I} \mathbf{E} - \overline{\mathbf{SS}} \mathbf{E} \quad (5-122a)$$

$$\overline{\mathbf{SS}} = \epsilon \mathbf{I} \mathbf{A} \mathbf{I} \mathbf{R} \overline{\mathbf{SS}} \epsilon \mathbf{I} \quad (5-122b)$$

with again

$$\mathbf{R} \equiv [\mathbf{A} \mathbf{I} - \overline{\mathbf{SS}} \rho \mathbf{I}]^{-1} \quad (5-122c)$$

The radiant surface flux vector  $\mathbf{Q}$ , as computed from Eq. (5-122a), always satisfies the (scalar) conservation condition  $\mathbf{1}_M^T \mathbf{Q} = \mathbf{0}$  or  $\sum_{i=1}^M Q_i = 0$ , which is a statement of the overall radiant energy balance.

The matrix conservation relations also simplify to

$$\mathbf{A} \mathbf{I} \mathbf{I}_M = \overline{\mathbf{SS}} \mathbf{I}_M \quad (5-123a)$$

$$\epsilon \mathbf{I} \mathbf{A} \mathbf{I} \mathbf{I}_M = \overline{\mathbf{SS}} \mathbf{I}_M \quad (5-123b)$$

And the  $M \times M$  arrays for all the direct and total view factors can be readily computed from

$$\mathbf{F} = \mathbf{A} \mathbf{I}^{-1} \overline{\mathbf{SS}} \quad (5-124a)$$

and

$$\mathcal{F} = \mathbf{A} \mathbf{I}^{-1} \overline{\mathbf{SS}} \quad (5-124b)$$

where the following matrix conservation relations must also be satisfied,

$$\mathbf{F} \cdot \mathbf{I}_M = \mathbf{I}_M \quad (5-125a)$$

and

$$\mathcal{F} \cdot \mathbf{I}_M = \epsilon \mathbf{I} \cdot \mathbf{I}_M \quad (5-125b)$$

**The Two-Zone Enclosure** Figure 5-18 depicts four simple enclosure geometries which are particularly useful for engineering calculations characterized by only two surface zones. For  $M = 2$ , the reflectivity matrix  $\mathbf{R}$  is readily evaluated in closed form since an explicit algebraic inversion formula is available for a  $2 \times 2$  matrix. In this case knowledge of only  $\Sigma = 1$  direct exchange area is required. Direct evaluation of Eqs. (5-122) then leads to

$$\overline{\mathbf{SS}} = \begin{bmatrix} \epsilon_1 A_1 - S_1 S_2 & S_1 S_2 \\ S_1 S_2 & \epsilon_2 A_2 - S_1 S_2 \end{bmatrix} \quad (5-126)$$

where

$$\overline{S_1 S_2} = \frac{1}{\left( \frac{1}{s_1 s_2} + \frac{\rho_1}{\epsilon_1 A_1} + \frac{\rho_2}{\epsilon_2 A_2} \right)} \quad (5-127)$$

Equation (5-127) is of general utility for any two-zone system for which  $\epsilon_i \neq 0$ .

The total exchange areas for the four geometries shown in Fig. 5-18 follow directly from Eqs. (5-126) and (5-127).

1. A planar surface  $A_1$  completely surrounded by a second surface  $A_2 > A_1$ . Here  $F_{1,1} = 0$ ,  $F_{1,2} = 1$ , and  $\overline{S_1 S_2} = A_1$ , resulting in

$$\overline{\mathbf{SS}} = \begin{bmatrix} \epsilon_1 \rho_2 A_1^2 + \epsilon_2 \rho_1 A_1 A_2 & \epsilon_1 \epsilon_2 A_1 A_2 \\ \epsilon_1 \epsilon_2 A_1 A_2 & \epsilon_2 A_2^2 + \epsilon_1 (\rho_2 - \epsilon_2) A_1 A_2 \end{bmatrix} / [\epsilon_1 \rho_2 A_1 + \epsilon_2 A_2]$$

and in particular  $\overline{S_1 S_2} = \frac{A_1}{1/\epsilon_1 + (A_1/A_2)(\rho_2/\epsilon_2)}$  (5-127a)

In the limiting case, where  $A_1$  has no negative curvature and is completely surrounded by a very much larger surface  $A_2$  such that  $A_1 \ll A_2$ , Eq. (5-127a) leads to the even simpler result that  $\overline{S_1 S_2} = \epsilon_1 A_1$ .

2. Two parallel plates of equal area which are large compared to their distance of separation (infinite parallel plates). Case 2 is a limiting form of case 1 with  $A_1 = A_2$ . Algebraic manipulation then results in

$$\overline{\mathbf{SS}} = \begin{bmatrix} (\epsilon_1 + \epsilon_2 - 2\epsilon_1 \epsilon_2) A_1 & \epsilon_1 \epsilon_2 A_1 \\ \epsilon_1 \epsilon_2 A_1 & (\epsilon_1 + \epsilon_2 - 2\epsilon_1 \epsilon_2) A_1 \end{bmatrix} / [\epsilon_1 + \epsilon_2 - \epsilon_1 \epsilon_2]$$

and in particular

$$\overline{S_1 S_2} = \frac{A_1}{1/\epsilon_1 + 1/\epsilon_2 - 1} \quad (5-127b)$$

| Case 1  | Case 2  | Case 3  | Case 4  |
|---|---|---|---|
|  |  |  |       |
| A planar surface $A_1$ completely surrounded by a second surface $A_2 > A_1$ .      | Two infinite parallel plates where $A_1 = A_2$ .                                    | Concentric spheres or infinite cylinders where $A_1 < A_2$ . Identical to Case 1.   | A speckled enclosure with two surface zones.  |
| $\mathbf{F} = \begin{bmatrix} 0 & 1 \\ A_1/A_2 & 1 - A_1/A_2 \end{bmatrix}$         | $\mathbf{F} = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$                         | $\mathbf{F} = \begin{bmatrix} 0 & 1 \\ A_1/A_2 & 1 - A_1/A_2 \end{bmatrix}$         | $\mathbf{F} = \frac{1}{(A_1 + A_2)} \begin{bmatrix} A_1 & A_2 \\ A_1 & A_2 \end{bmatrix}$ |

**FIG. 5-18** Four enclosure geometries characterized by two surface zones and one volume zone. (Marks' Standard Handbook for Mechanical Engineers, McGraw-Hill, New York, 1999, p. 4-73, Table 4.3.5.)

3. Concentric spheres or cylinders where  $A_2 > A_1$ . Case 3 is mathematically identical to case 1.

4. A **speckled enclosure** with two surface zones. Here  $\mathbf{F} = \frac{1}{A_1 + A_2} \begin{bmatrix} A_1 & A_2 \\ A_1 & A_2 \end{bmatrix}$  such that  $\overline{\mathbf{SS}} = \frac{1}{A_1 + A_2} \begin{bmatrix} A_1^2 & A_1 A_2 \\ A_1 A_2 & A_2^2 \end{bmatrix}$  and Eqs.

(5-126) and (5-127) then produce

$$\overline{\mathbf{SS}} = \begin{bmatrix} \epsilon_1^2 A_1^2 & \epsilon_1 \epsilon_2 A_1 A_2 \\ \epsilon_1 \epsilon_2 A_1 A_2 & \epsilon_2^2 A_2^2 \end{bmatrix} / (\epsilon_1 A_1 + \epsilon_2 A_2)$$

with the particular result

$$\overline{S_1 S_2} = \frac{1}{1/(\epsilon_1 A_1) + 1/(\epsilon_2 A_2)} \quad (5-127c)$$

Physically, a two-zone speckled enclosure is characterized by the fact that the view factor from any point on the enclosure surface to the sink zone is identical to that from any other point on the bounding surface. This is only possible when the two zones are "intimately mixed." The seemingly simplistic concept of a speckled enclosure provides a surprisingly useful *default option* in engineering calculations when the *actual* enclosure geometries are quite complex.

**Multizone Enclosures [ $M \geq 3$ ]** Again assume  $K = 0$ . The major numerical effort involved in implementation of the zone method is the evaluation of the inverse reflection matrix  $\mathbf{R}$ . For  $M = 3$ , explicit closed-form algebraic formulas *do indeed exist* for the nine scalar elements of the inverse of any arbitrary nonsingular matrix. These formulas are so algebraically complex, however, that it proves impractical to present universal closed-form expressions for the total exchange areas, as has been done for the case  $M = 2$ . Fortunately, many practical furnace configurations can be idealized with zoning such that only relatively simple *hand calculation procedures are required*. Here the enclosure is modeled with only  $M = 3$  surface zones, e.g., a single source, a single sink, and a lumped adiabatic refractory zone. This approach is sometimes termed the **SSR model**. The SSR model assumes that all adiabatic refractory surfaces are *perfect diffuse mirrors*. To implement the SSR procedure, it is necessary to develop *specialized algebraic formulas* and to define a *third black view factor*  $F_{ij}$  with an *overbar* as follows.

**Refractory Augmented Black View Factors  $\overline{F}_{ij}$**  Let  $M = M_r + M_b$ , where  $M_b$  is the number of black surface zones and  $M_r$  is the number of adiabatic refractory zones. Assume  $\epsilon_r = 0$  or  $\rho_r = 1$  or, equivalently, that all adiabatic refractory surfaces are *perfect diffuse mirrors*. The view factor  $\overline{F}_{ij}$  is then defined as the **refractory augmented black view factor**, i.e., the direct view factor between *any two* black source-sink zones,  $A_i$  and  $A_j$ , with *full allowance for reflections from all intervening refractory surfaces*. The quantity  $\overline{F}_{ij}$  shall be referred to as **F-bar**, for expediency.

Consider the special situation where  $M_b = 2$ , with any number of refractory zones  $M_r \geq 1$ . By use of appropriate row and column reduction of the reflectivity matrix  $\mathbf{R}$ , an especially useful relation can be derived that allows computation of the conventional total exchange area  $S_i S_j$  from the *corresponding refractory augmented black view factor*  $\overline{F}_{ij}$

$$\overline{S_1 S_2} = \frac{1}{\left( \frac{\rho_1}{\epsilon_1 A_1} + \frac{\rho_2}{\epsilon_2 A_2} + \frac{1}{A_1 \overline{F}_{1,2}} \right)} \quad (5-128a)$$

or

$$\overline{F}_{1,2} = \frac{1}{\left( \frac{\rho_1}{\epsilon_1} + \left( \frac{A_1}{A_2} \right) \cdot \frac{\rho_2}{\epsilon_2} + \frac{1}{\overline{F}_{1,2}} \right)} \quad (5-128b)$$

where  $\epsilon_i \neq 0$ . Notice that Eq. (5-128a) appears *deceptively similar* to Eq. (5-127). Collectively, Eqs. (5-128) along with various formulas to compute  $\overline{F}_{ij}$  (*F-bar*) are sometimes called the three-zone source/sink/refractory **SSR model**.

The following formulas permit the calculation of  $\overline{F}_{ij}$  from requisite *direct* exchange areas. For the special case where the enclosure is divided into *any number of* black source-sink zones,  $M_b \geq 2$ , and the remainder of the enclosure is lumped together into a single refractory

zone ( $M_r = 1$ ) with total area  $A_r$  and uniform average temperature  $T_r$ , then the direct refractory augmented exchange area for the black zone pairs is given by

$$A_i \overline{F}_{i,j} = A_j \overline{F}_{j,i} = \overline{s_i s_j} + \frac{\overline{s_i s_r} \overline{s_r s_j}}{A_r - \overline{s_r s_r}} \quad \text{for } 1 \leq i, j \leq M_b \quad (5-129)$$

For the special case  $M_b = 2$  and  $M_r = 1$ , Eq. (5-129) then simplifies to

$$A_1 \overline{F}_{1,2} = A_2 \overline{F}_{2,1} = \overline{s_1 s_2} + \frac{1}{1/\overline{s_1 s_r} + 1/\overline{s_2 s_r}} \quad (5-130)$$

and if  $\overline{s_1 s_r} = \overline{s_2 s_r} = 0$ , Eq. (5-130) further reduces to

$$A_1 \overline{F}_{1,2} = \overline{s_1 s_2} + \frac{1}{1/(A_1 - \overline{s_1 s_2}) + 1/(A_2 - \overline{s_2 s_1})} = \frac{A_1 A_2 - (\overline{s_1 s_2})^2}{A_1 + A_2 - 2\overline{s_1 s_2}} \quad (5-131)$$

which necessitates the evaluation of only one direct exchange area. Let the  $M_r$  refractory zones be numbered *last*. Then the  $M_b \times M_b$  array of refractory augmented direct exchange areas  $[A_i \overline{F}_{i,j}]$  is symmetric and satisfies and the conservation relation

$$[A_i \overline{F}_{i,j}] \cdot \mathbf{1}_{M_b} = \mathbf{A} \cdot \mathbf{1}_{M_b} \quad (5-132a)$$

with

$$\overline{\mathbf{F}} \cdot \mathbf{1}_{M_b} = \mathbf{1}_{M_b} \quad (5-132b)$$

Temporarily denote  $\overline{S_1 S_2}_R$  as the value of  $\overline{S_1 S_2}$  computed from Eq. (5-128a) which assumes  $\epsilon_r = 0$ . It remains to demonstrate the relationship between  $\overline{S_1 S_2}_R$  and the total exchange area  $S_1 S_2$  computed from the matrix method for  $M = 3$  when zone 3 is an adiabatic refractory for which  $Q_3 = 0$  and  $\epsilon_3 \neq 0$ . Let  $\Theta_i = (E_i - E_2)/(E_1 - E_2)$  denote the dimensionless emissive power where  $E_1 > E_2$  such that  $\Theta_1 = 1$  and  $\Theta_2 = 0$ . The dimensionless refractory emissive power may then be calculated from Eq. (5-121) as  $\Theta_3 = S_3 S_1 / [S_3 S_1 + S_3 S_2]$ , which when substituted into Eq. (5-122a) leads to  $S_1 S_2_R = \overline{S_1 S_2} + \overline{S_2 S_3} \Theta_3 = \overline{S_1 S_2} + \overline{S_1 S_3} \cdot S_3 S_2 / [S_3 S_1 + S_3 S_2]$ . Thus  $\overline{S_1 S_2}_R$  is clearly the *refractory-aided* total exchange area between zone 1 and zone 2 and *not*  $\overline{S_1 S_2}$  as calculated by the matrix method in general. That is,  $\overline{S_1 S_2}_R$  includes not only the radiant energy originating at zone 1 and arriving at zone 2 directly and by reflection from zones 2 and 3, but also radiation originating at zone 1 that is *absorbed* by zone 3 and then wholly reemitted to zone 2; that is,  $H_3 = W_3 = E_3$ .

Evaluation of any total view factor  $\mathcal{F}_{ij}$  using the requisite refractory augmented black view factor  $\overline{F}_{ij}$  obviously requires that the latter be readily available and/or capable of calculation. The refractory augmented view factor  $\overline{F}_{ij}$  is documented for a few geometrically simple cases and can be calculated or approximated for others. If  $A_1$  and  $A_2$  are equal parallel disks, squares, or rectangles, connected by nonconducting but reradiating refractory surfaces, then  $\overline{F}_{ij}$  is given by Fig. 5-13 in curves 5 to 8. Let  $A_1$  represent an infinite plane and  $A_2$  represent one or two rows of infinite parallel tubes. If the only other surface is an adiabatic refractory surface located behind the tubes,  $\overline{F}_{2,1}$  is then given by curve 5 or 6 of Fig. 5-15.

Experience has shown that the simple SSR model can yield quite useful results for a host of practical engineering applications without resorting to digital computation. The error due to representation of the source and sink by single zones is often small, even if the views of the enclosure from different parts of the same zone are dissimilar, provided the surface emissivities are near unity. The error is also small if the temperature variation of the refractory is small. Any degree of accuracy can, of course, be obtained via the matrix method for arbitrarily large  $M$  and  $N$  by using a digital computer. From a computational viewpoint, when  $M \geq 4$ , the matrix method *must be used*. The matrix method must also be used for finer-scale calculations such as more detailed wall temperature and flux density profiles.

**The Electrical Network Analog** At each surface zone the *total* radiant flux is proportional to the difference between  $E_i$  and  $W_i$ , as indicated by the equation  $Q_i = (\epsilon_i A_i \rho_i)(E_i - W_i)$ . The *net* flux between zones  $i$  and  $j$  is also given by  $Q_{ij} = s_i s_j (W_i - W_j)$ , where  $Q_i = \sum_{j=1}^M Q_{ij}$ , for all  $1 \leq i \leq M$ , is the *total* heat flux leaving each zone. These relations

**FIG. 5-19** Generalized electrical network analog for a three-zone enclosure. Here  $A_1$  and  $A_2$  are gray surfaces and  $A_r$  is a radiatively adiabatic surface. (Hottel, H. C., and A. F. Sarofim, Radiative Transfer, McGraw-Hill, New York, 1967, p. 91.)

suggest a visual electrical analog in which  $E_i$  and  $W_i$  are analogous to voltage potentials. The quantities  $\epsilon_i A_i / \rho_i$  and  $s_i s_j$  are analogous to conductances (reciprocal impedances), and  $Q_i$  or  $Q_{ij}$  is analogous to electric currents. Such an electrical analog has been developed by Oppenheim [Oppenheim, A. K., Trans. ASME, 78, 725-735 (1956)].

Figure 5-19 illustrates a generalized electrical network analog for a three-zone enclosure consisting of one refractory zone and two gray zones  $A_1$  and  $A_2$ . The potential points  $E_i$  and  $W_i$  are separated by conductances  $\epsilon_i A_i / \rho_i$ . The emissive powers  $E_1$ ,  $E_2$  represent potential sources or sinks, while  $W_1$ ,  $W_2$ , and  $W_r$  are internal node points. In this construction the nodal point representing each surface is connected to that of every other surface it can see directly. Figure 5-19 can be used to formulate the total exchange area  $S_1 S_2$  for the SSR model virtually by inspection. The refractory zone is first characterized by a floating potential such that  $E_r = W_r$ . Next, the resistance for the parallel "current paths" between the internal nodes  $W_1$  and  $W_2$  is defined by  $\frac{1}{A_1 F_{1,2}} \equiv \frac{1}{s_1 s_2 + 1/(1/s_1 s_r + 1/s_2 s_r)}$  which is identical to Eq. (5-130).

Finally, the overall impedance between the source  $E_1$  and the sink  $E_2$  is represented simply by three resistors in series and is thus given by

$$\frac{1}{S_1 S_2} = \frac{\rho_1}{\epsilon_1 A_1} + \frac{1}{A_1 F_{1,2}} + \frac{\rho_2}{\epsilon_2 A_2}$$

or

$$\frac{1}{S_1 S_2} = \frac{1}{\frac{\rho_1}{\epsilon_1 A_1} + \frac{\rho_2}{\epsilon_2 A_2} + \frac{1}{A_1 F_{1,2}}} \quad (5-133)$$

This result is identically that for the SSR model as obtained previously in Eq. (5-128a). This equation is also valid for  $M_r \geq 1$  as long as  $M_b = 2$ . The electrical network analog methodology can be generalized for enclosures having  $M > 3$ .

**Some Examples from Furnace Design** The theory of the past several subsections is best understood in the context of two engineering examples involving furnace modeling. The engineering idealization of the **equivalent gray plane concept** is introduced first. Figure 5-20 depicts a common furnace configuration in which the

**FIG. 5-20** Furnace chamber cross section. To convert feet to meters, multiply by 0.3048.

heating source is two refractory-backed, internally fired tube banks. Clearly the overall geometry for even this common furnace configuration is too complex to be modeled in an expeditious manner by anything other than a simple engineering idealization. Thus the furnace shown in Fig. 5-20 is modeled in Example 10, by partitioning the entire enclosure into two subordinate furnace compartments. The approach first defines an imaginary gray plane  $A_2$ , located on the inward-facing side of the tube assemblies. Second, the total exchange area between the tubes to this equivalent gray plane is calculated, making full allowance for the reflection from the refractory tube backing. The plane-to-tube view factor is then defined to be the emissivity of the required equivalent gray plane whose temperature is further assumed to be that of the tubes. This procedure guarantees continuity of the radiant flux into the interior radiant portion of the furnace arising from a moderately complicated external source.

Example 9 demonstrates classical zoning calculations for radiation pyrometry in furnace applications. Example 10 is a classical furnace design calculation via zoning an enclosure with a diathermanous atmosphere and  $M = 4$ . The latter calculation can only be addressed with the matrix method. The results of Example 10 demonstrate the relative insensitivity of zoning to  $M > 3$  and the engineering utility of the SSR model.

**Example 9: Radiation Pyrometry** A long tunnel furnace is heated by electrical resistance coils embedded in the ceiling. The stock travels on a floor-mounted conveyor belt and has an estimated emissivity of 0.7. The sidewalls are unheated refractories with emissivity 0.55, and the ceiling emissivity is 0.8. The furnace cross section is rectangular with height 1 m and width 2 m. A total radiation pyrometer is sighted on the walls and indicates the following apparent temperatures: ceiling, 1340°C; sidewall readings average about 1145°C; and the load indicates about 900°C. (a) What are the true temperatures of the furnace walls and stock? (b) What is the net heat flux at each surface? (c) How do the matrix method and SSR models compare?

*Three-zone model,  $M = 3$ :*

Zone 1: Source (top)

Zone 2: Sink (bottom)

Zone 3: Refractory (lumped sides)

*Physical constants:*

$$T_0 \equiv 273.15 \text{ K} \quad \sigma \equiv 5.670400 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4}$$

*Enclosure input parameters:*

$$H_c := 1 \text{ m} \quad W_c := 2 \text{ m} \quad L_c := 1 \text{ m} \quad A_1 := W_c L_c \quad A_2 := A_1 \quad A_3 := 2H_c L_c$$

$$\epsilon_1 := .8 \quad \epsilon_2 := .7 \quad \epsilon_3 := .55 \quad \rho_1 := 1 - \epsilon_1 \quad \rho_2 := 1 - \epsilon_2 \quad \rho_3 := 1 - \epsilon_3$$

$$\mathbf{AI} := \begin{bmatrix} A_1 & 0 & 0 \\ 0 & A_2 & 0 \\ 0 & 0 & A_3 \end{bmatrix} \quad \mathbf{eI} := \begin{bmatrix} \epsilon_1 & 0 & 0 \\ 0 & \epsilon_2 & 0 \\ 0 & 0 & \epsilon_3 \end{bmatrix} \quad \mathbf{\rho I} := \begin{bmatrix} \rho_1 & 0 & 0 \\ 0 & \rho_2 & 0 \\ 0 & 0 & \rho_3 \end{bmatrix}$$

$$\mathbf{AI} := \begin{bmatrix} 2 & 0 & 0 \\ 0 & 2 & 0 \\ 0 & 0 & 2 \end{bmatrix} \text{m}^2 \quad \mathbf{eI} := \begin{bmatrix} 0.8 & 0 & 0 \\ 0 & 0.7 & 0 \\ 0 & 0 & 0.55 \end{bmatrix} \quad \mathbf{\rho I} := \begin{bmatrix} 0.2 & 0 & 0 \\ 0 & 0.3 & 0 \\ 0 & 0 & 0.45 \end{bmatrix}$$

*Compute direct exchange areas by using crossed strings ( $\Sigma = 3$ ):*

$$ss_{11} := 0 \quad ss_{22} := 0 \quad ss_{33} := 2(\sqrt{H_c^2 + W_c^2} - W_c)L_c \quad ss_{33} := 0.4721 \text{ m}^2$$

From symmetry and conservation, there are three linear simultaneous results for the off-diagonal elements of  $\mathbf{ss}$ :

$$\begin{bmatrix} 12 \\ 13 \\ 23 \end{bmatrix} = \begin{bmatrix} 1 & 1 & 0 \\ 1 & 0 & 1 \\ 0 & 1 & 1 \end{bmatrix}^{-1} \begin{bmatrix} A_1 - 11 \\ A_2 - 22 \\ A_3 - 33 \end{bmatrix} = \frac{1}{2} \begin{bmatrix} 1 & 1 & -1 \\ 1 & -1 & 1 \\ -1 & 1 & 1 \end{bmatrix}$$

$$\times \begin{bmatrix} A_1 - 11 \\ A_2 - 22 \\ A_3 - 33 \end{bmatrix} = \frac{1}{2} \begin{bmatrix} +A_1 + A_2 - A_3 - 11 - 22 + 33 \\ +A_1 - A_2 + A_3 - 11 + 22 - 33 \\ -A_1 + A_2 + A_3 + 11 - 22 - 33 \end{bmatrix}$$

Thus

$$ss_{12} := 0.5 (A_1 + A_2 - A_3 + ss_{33}) \quad ss_{13} := 0.5 (A_1 - A_2 + A_3 - ss_{33}) \quad ss_{23} := 0.5 (-A_1 + A_2 + A_3 - ss_{33})$$

$$\mathbf{ss} := \begin{bmatrix} ss_{11} & ss_{12} & ss_{13} \\ ss_{12} & ss_{22} & ss_{23} \\ ss_{13} & ss_{23} & ss_{33} \end{bmatrix} \quad \mathbf{ss} := \begin{bmatrix} 0 & 1.2361 & 0.7639 \\ 1.2361 & 0 & 0.7639 \\ 0.7639 & 0.7639 & 0.4721 \end{bmatrix} \text{m}^2 \quad (\mathbf{AI} - \mathbf{ss}) \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \text{m}^2$$

*Compute radiosities  $W$  from pyrometer temperature readings:*

$$\mathbf{T}_{wc} := \begin{bmatrix} 1340.0 \\ 900.0 \\ 1145.0 \end{bmatrix} \text{C} \quad \mathbf{W} := \sigma \left( \mathbf{T}_{wc} \frac{\text{K}}{\text{C}} + T_0 \right)^4 \quad \mathbf{W} := \begin{bmatrix} 384.0 \\ 107.4 \\ 229.4 \end{bmatrix} \frac{\text{kW}}{\text{m}^2}$$

Matrix wall flux density relations and heat flux calculations based on W:

$$\mathbf{H} := \mathbf{AI}^{-1}\mathbf{ss}\cdot\mathbf{W} \quad \mathbf{Q} := \mathbf{AI}(\mathbf{W} - \mathbf{H}) \quad \mathbf{E} := (\mathbf{eI}\cdot\mathbf{AI})^{-1}\cdot\mathbf{Q} + \mathbf{H}$$

$$\mathbf{H} := \begin{bmatrix} 154.0 \\ 324.9 \\ 241.8 \end{bmatrix} \frac{\text{kW}}{\text{m}^2} \quad \mathbf{Q} := \begin{bmatrix} 460.0 \\ -435.0 \\ -25.0 \end{bmatrix} \text{kW} \quad \mathbf{E} := \begin{bmatrix} 441.5 \\ 14.2 \\ 219.1 \end{bmatrix} \frac{\text{kW}}{\text{m}^2}$$

The sidewalls act as near-adiabatic surfaces since the heat loss through each sidewall is only about 2.7 percent of the total heat flux originating at the source.

Actual temperatures versus pyrometer readings:

$$\mathbf{T} := \left[ \left( \frac{\text{E}}{\sigma} \right)^{0.25} - T_0 \right] \frac{\text{C}}{\text{K}} \quad \mathbf{T} = \begin{bmatrix} 1397.3 \\ 434.1 \\ 1128.9 \end{bmatrix} \text{C} \quad \text{versus} \quad \mathbf{T}_{wc} = \begin{bmatrix} 1340.0 \\ 900.0 \\ 1145.0 \end{bmatrix} \text{C}$$

Compare SSR model versus matrix method [use Eqs. (5-128a) and (5-130)]: From Eq. (5-130)

$$\text{ssbar}_{12} := \text{ss}_{1,2} + \frac{1}{\frac{1}{\text{ss}_{1,3}} + \frac{1}{\text{ss}_{2,3}}} \quad \text{ssbar}_{12} = 1.6180 \text{ m}^2$$

And from Eq. (5-128a)

$$\text{SSR}_{12} := \frac{1}{\frac{\rho_1}{\epsilon_1 A_1} + \frac{\rho_2}{\epsilon_2 A_2} + \frac{1}{\text{ssbar}_{12}}} \quad \text{SSR}_{12} = 1.0446 \text{ m}^2$$

With the numerical result  $Q_{12} := \text{SSR}_{12}(E_1 - E_2) \quad Q_{12} = 446.3 \text{ kW}$

Thus the SSR model produces  $Q_{12} = 446.3 \text{ kW}$  versus the measured value  $Q_1 = 460.0 \text{ kW}$  or a discrepancy of about 3.0 percent. Mathematically the SSR model assumes a value of  $\epsilon_3 = 0.0$ , which precludes the sidewall heat loss of  $Q_3 = -25.0 \text{ kW}$ . This assumption accounts for all of the difference between the two values. It remains to compare  $\text{SSR}_{12}$  and  $\text{SS}_{1,2}$  computed by the matrix method.

Compute total exchange areas ( $\epsilon_3 = 0.55$ ):

$$\mathbf{R} := (\mathbf{AI} - \overline{\text{ss}}\cdot\mathbf{pI})^{-1}$$

$$\overline{\text{SS}} := \mathbf{eI}\cdot\mathbf{AI}\cdot\mathbf{R}\cdot\overline{\text{ss}}\cdot\mathbf{eI} \quad \overline{\text{SS}} = \begin{bmatrix} 0.2948 & 0.8284 & 0.4769 \\ 0.8284 & 0.1761 & 0.3955 \\ 0.4769 & 0.3955 & 0.2277 \end{bmatrix} \text{m}^2 \quad (\mathbf{eI}\cdot\mathbf{AI} - \overline{\text{SS}}) \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix} \text{m}^2$$

Clearly  $\text{SSR}_{21}$  and  $\text{SS}_{1,2}$  are unequal. But if

$$\Theta_3 := \frac{\text{SS}_{3,1}}{\text{SS}_{3,1} + \text{SS}_{3,2}}$$

define

$$\text{SSA}_{12} := \text{SS}_{1,2} + \text{SS}_{2,3}\cdot\Theta_3$$

and

$$\Theta_3 := 0.5466 \quad \text{SSA}_{12} = 1.0446 \text{ m}^2 \quad E_r := E_2 + (E_1 - E_2)\cdot\Theta_3 \quad E_r = 247.8 \frac{\text{kW}}{\text{m}^2}$$

Numerically the matrix method predicts  $\text{SSA}_{12} = 1.0446 \text{ m}^2$  for  $Q_3 = 0$  and  $\epsilon_3 = 0.55$ , which is identical to  $\text{SSR}_{1,2}$  for the SSR model. Thus  $\text{SSR}_{1,2} = \text{SSA}_{12}$  is the refractory-aided total exchange area between zone 1 and zone 2. The SSR model also predicts  $E_r = 247.8 \text{ kW/m}^2$  versus the experimental value  $E_3 = 219.1 \text{ kW/m}^2$  (1172.6C vs. 1128.9C), which is also a consequence of the actual 25.0-kW refractory heat loss.

(This example was developed as a MATHCAD 14® worksheet. Mathcad is a registered trademark of Parametric Technology Corporation.)

**Example 10: Furnace Simulation via Zoning** The furnace chamber depicted in Fig. 5-20 is heated by combustion gases passing through 20 vertical radiant tubes which are backed by refractory sidewalls. The tubes have an outside diameter of  $D = 5$  in (12.7 cm) mounted on  $C = 12$  in (4.72 cm) centers and a gray body emissivity of 0.8. The interior (radiant) portion of the furnace is a  $6 \times 8 \times 10$  ft rectangular parallelepiped with a total surface area of  $376 \text{ ft}^2$  ( $34.932 \text{ m}^2$ ). A  $50\text{-ft}^2$  ( $4.645\text{-m}^2$ ) sink is positioned centrally on the floor of the furnace. The tube and sink temperatures are measured with embedded thermocouples as 1500 and 1200°F, respectively. The gray refractory emissivity may be taken as 0.5. While all other refractories are assumed to be radiatively adia-

batic, the roof of the furnace is estimated to lose heat to the surroundings with a flux density ( $\text{W/m}^2$ ) equal to 5 percent of the source and sink emissive power difference. An estimate of the radiant flux arriving at the sink is required, as well as estimates for the roof and average refractory temperatures in consideration of refractory service life.

*Part (a): Equivalent Gray Plane Emissivity* Algebraically compute the equivalent gray plane emissivity for the refractory-backed tube bank idealized by the imaginary plane  $A_2$ , depicted in Fig. 5-15.

*Solution:* Let zone 1 represent one tube and zone 2 represent the effective plane 2, that is, the unit cell for the tube bank. Thus  $A_1 = \pi D$  and  $A_2 = C$  are the corresponding zone areas, respectively (per unit vertical dimension). This notation is consistent with Example 3. Also put  $\epsilon_1 = 0.8$  with  $\epsilon_2 = 1.0$  and define  $R = C/D = 12/5 = 2.4$ . The gray plane effective emissivity is then calculated as the total view factor for the effective plane to tubes, that is,  $\mathcal{F}_{2,1} \equiv \bar{\epsilon}_2$ . For  $R = 2.4$ , Fig. 5-15, curve 5, yields the refractory augmented view factor  $\bar{F}_{2,1} \approx 0.81$ . Then  $\mathcal{F}_{2,1}$  is calculated from Eq. (5-128b) as  $\mathcal{F}_{2,1} = \frac{1}{0/1 + (2.4/\pi) \cdot 0.2/0.8 + 1/0.81} \approx 0.702$ .

A more accurate value is obtained via the matrix method as  $\mathcal{F}_{2,1} = 0.70295$ .

*Part (b): Radiant Furnace Chamber with Heat Loss*

*Four-zone model, M = 4: Use matrix method.*

Zone 1: Sink (floor)

Zone 2: Source (lumped sides)

Zone 3: Refractory (roof)

Zone 4: Refractory (ends and floor strips)

*Physical constants:*

$$T_0 \equiv 273.15 \text{ K} \quad \sigma \equiv 5.6704 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4}$$

*Enclosure input parameters:*

$A_1 := 50 \text{ ft}^2 \quad A_2 := 120 \text{ ft}^2 \quad A_3 := 80 \text{ ft}^2 \quad A_4 := 126 \text{ ft}^2 \quad D := 5 \text{ in} \quad H := 6 \text{ ft}$

$\epsilon_1 := .9 \quad \epsilon_2 := .70295 \quad \epsilon_3 := .5 \quad \epsilon_4 := .5 \quad \mathbf{I}_4 := \text{identity}(4)$

$$\mathbf{eI} = \begin{bmatrix} 0.9 & 0 & 0 & 0 \\ 0 & 0.7029 & 0 & 0 \\ 0 & 0 & 0.5 & 0 \\ 0 & 0 & 0 & 0.5 \end{bmatrix} \quad \mathbf{pI} := \mathbf{I}_4 - \mathbf{eI} \quad \mathbf{pI} = \begin{bmatrix} 0.1 & 0 & 0 & 0 \\ 0 & 0.2971 & 0 & 0 \\ 0 & 0 & 0.5 & 0 \\ 0 & 0 & 0 & 0.5 \end{bmatrix}$$

*Compute direct exchange areas:* There are  $\Sigma = 6$  unique direct exchange areas. These are obtained from Eqs. (5-114) and view factor algebra. The final array of direct exchange areas is:

$$\overline{\text{ss}} = \begin{bmatrix} 0 & 1.559 & 1.575 & 1.511 \\ 1.559 & 2.078 & 2.839 & 4.673 \\ 1.575 & 2.839 & 0 & 3.018 \\ 1.511 & 4.673 & 3.018 & 2.503 \end{bmatrix} \text{m}^2 \quad \mathbf{AI} = \begin{bmatrix} 4.645 & 0 & 0 & 0 \\ 0 & 11.148 & 0 & 0 \\ 0 & 0 & 7.432 & 0 \\ 0 & 0 & 0 & 11.706 \end{bmatrix} \text{m}^2$$

*Compute total exchange areas:*

$$\mathbf{R} := (\mathbf{AI} - \overline{\text{ss}}\cdot\mathbf{pI})^{-1}$$

$$\overline{\text{SS}} := \mathbf{eI}\cdot\mathbf{AI}\cdot\mathbf{R}\cdot\overline{\text{ss}}\cdot\mathbf{eI} \quad \overline{\text{SS}} = \begin{bmatrix} 0.405 & 1.669 & 0.955 & 1.152 \\ 1.669 & 2.272 & 1.465 & 2.431 \\ 0.955 & 1.465 & 0.234 & 1.063 \\ 1.152 & 2.431 & 1.063 & 1.207 \end{bmatrix} \text{m}^2$$

*Check matrix conservation via row-sums:*

$$(\mathbf{AI} - \overline{\text{ss}}) \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \text{m}^2 \quad (\mathbf{eI}\cdot\mathbf{AI} - \overline{\text{SS}}) \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \text{m}^2$$

*Emissive power and wall flux input data:*

$$\mathbf{T}_F := \begin{bmatrix} 1200 \\ 1500 \\ 32 \\ 32 \end{bmatrix} \text{F} \quad \mathbf{T} := \frac{5}{9} (\mathbf{T}_F - 32 \text{ F}) \frac{\text{C}}{\text{F}} \quad \mathbf{E} := \sigma \left( \mathbf{T} \frac{\text{K}}{\text{C}} + T_0 \right)^4$$

$$\mathbf{T} = \begin{bmatrix} 648.9 \\ 815.6 \\ 0.0 \\ 0.0 \end{bmatrix} \text{C} \quad \mathbf{E} = \begin{bmatrix} 40.98 \\ 79.66 \\ 0.32 \\ 0.32 \end{bmatrix} \frac{\text{kW}}{\text{m}^2}$$

$$Q_3 := -0.05 \cdot A_3 (E_2 - E_1) \quad Q_3 = -14.37 \text{ kW} \quad Q_4 := 0$$

### 5-30 HEAT AND MASS TRANSFER

Compute refractory emissive powers from known flux inputs  $Q_3$  and  $Q_4$  using partitioned matrix equations [Eq. (5-120b)]:

$$\mathbf{E}_R := \begin{bmatrix} \epsilon_3 A_3 - SS_{3,3} & -SS_{3,4} \\ -SS_{4,3} & \epsilon_4 A_4 - SS_{4,4} \end{bmatrix}^{-1} \cdot \begin{bmatrix} Q_3 + SS_{3,1} E_1 + SS_{3,2} E_2 \\ Q_4 + SS_{4,1} E_1 + SS_{4,2} E_2 \end{bmatrix}$$

$$\mathbf{E}_R = \begin{bmatrix} 60.68 \\ 65.73 \end{bmatrix} \frac{\text{kW}}{\text{m}^2} \quad \mathbf{E} := \begin{bmatrix} E_1 \\ E_2 \\ E_{R1} \\ E_{R2} \end{bmatrix} \quad \mathbf{E} = \begin{bmatrix} 40.98 \\ 79.66 \\ 60.68 \\ 65.73 \end{bmatrix} \frac{\text{kW}}{\text{m}^2}$$

Compute flux values and final zone temperatures:

$$\mathbf{Q} := \epsilon \mathbf{I} \cdot \mathbf{A} \cdot \mathbf{E} - \overline{SS} \cdot \mathbf{E} \quad \mathbf{T} := \left[ \left( \frac{\mathbf{E}}{\sigma} \right)^{0.25} - T_0 \right] \frac{\text{C}}{\text{K}}$$

$$\mathbf{Q} = \begin{bmatrix} -111.87 \\ 126.24 \\ -14.37 \\ 0.00 \end{bmatrix} \text{kW} \quad \mathbf{T} = \begin{bmatrix} 648.9 \\ 815.6 \\ 743.9 \\ 764.5 \end{bmatrix} \text{C}$$

Auxiliary calculations for tube area and effective tube emissivity:

$$A_{\text{Tubes}} := 20\pi \cdot D \cdot H \quad \epsilon_{\text{Tubes}} := \frac{Q_2}{A_{\text{Tubes}}(E_2 - E_1)} \quad A_{\text{Tubes}} = 14.59 \text{ m}^2 \quad \epsilon_{\text{Tubes}} = 0.2237$$

Notes: (1) Results for  $Q$  and  $T$  here are independent of  $\epsilon_3$  and  $\epsilon_4$  with the exception of  $T_3$ , which is indeed a function of  $\epsilon_3$ . (2) The total surface area of the tubes is  $A_{\text{Tubes}} = 14.59 \text{ m}^2$ . Suppose the tubes were totally surrounded by a black enclosure at the temperature of the sink. The hypothetical emissivity of the tubes would then be  $\epsilon_{\text{Tubes}} = 0.224$ . (3) A 5 percent roof heat loss is consistent with practical measurement errors. A sensitivity test was performed with  $M = 3, 4, \text{ and } 5$  with and without roof heat loss. The SSR model corresponds to  $M = 3$  with zero heat loss. For  $M = 5$ , zone 4 corresponded to the furnace ends and zone 5 corresponded to the floor strips. The results are summarized in the following table. With the exception of the temperature of the floor strips, the computed results are seen to be remarkably insensitive to  $M$ .

Effect of Zone Number  $M$  on Computed Results

|                 | Zero roof heat loss |          |          | 5 percent roof heat loss |          |          |
|-----------------|---------------------|----------|----------|--------------------------|----------|----------|
|                 | $M = 3$             | $M = 4$  | $M = 5$  | $M = 3$                  | $M = 4$  | $M = 5$  |
| Temperature, °C |                     |          |          |                          |          |          |
| $T_3$           | 765.8               | 762.0    | 762.4    | 756.2                    | 743.9    | 744.3    |

(This example was developed as a MATHCAD 14® worksheet. Mathcad is a registered trademark of Parametric Technology Corporation.)

**Allowance for Specular Reflection** If the assumption that all surface zones are diffuse emitters and reflectors is relaxed, the zoning equations become much more complex. Here, all surface parameters become functions of the *angles of incidence and reflection* of the radiation beams at each surface. In practice, such details of reflectance and emission are seldom known. When they are, the Monte Carlo method of tracing a large number of beams emitted from random positions and in random initial directions is probably the best method of obtaining a solution. Siegel and Howell (op. cit., Chap. 10) and Modest (op. cit., Chap. 20) review the utilization of the Monte Carlo approach to a variety of radiant transfer applications. Among these is the Monte Carlo calculation of direct exchange areas for very complex geometries. Monte Carlo techniques are generally *not used* in practice for simpler engineering applications.

A simple *engineering* approach to specular reflection is the so-called **diffuse plus specular reflection model**. Here the total reflectivity  $\rho_i = 1 - \epsilon_i = \rho_{Si} + \rho_{Di}$  is represented as the sum of a *diffuse component*

$\rho_{Si}$  and a *specular component*  $\rho_{Di}$ . The method yields analytical results for a number of two surface zone geometries. In particular, the following equation is obtained for exchange between concentric spheres or infinitely long coaxial cylinders for which  $A_1 < A_2$ :

$$\overline{S_1 S_2} = \frac{A_1}{\left( \frac{1}{\epsilon_1} + \frac{\rho_2}{\epsilon_2} \frac{A_1}{A_2} + \frac{\rho_{S2}}{(1 - \rho_{S2})} [1 - A_1/A_2] \right)} \quad (5-134)$$

For  $\rho_{D1} = \rho_{D2} = 0$  (or equivalently  $\rho_1 = \rho_{S1}$  with  $\rho_2 = \rho_{S2}$ ), Eq. (5-134) yields the limiting case for wholly specular reflection, i.e.

$$\text{Specular limit} \quad \overline{S_1 S_2} = \frac{A_1}{\left( \frac{1}{\epsilon_1} + \frac{1}{\epsilon_2} - 1 \right)} \quad (5-134a)$$

which is independent of the area ratio,  $A_1/A_2$ . It is important to notice that Eq. (5-124a) is *similar* to Eq. (5-127b) but the emissivities here are defined as  $\epsilon_1 \equiv 1 - \rho_{S1}$  and  $\epsilon_2 \equiv 1 - \rho_{S2}$ . When surface reflection is wholly diffuse [ $\rho_{S1} = \rho_{S2} = 0$  or  $\rho_1 = \rho_{D1}$  with  $\rho_2 = \rho_{D2}$ ], Eq. (5-134) results in a formula *identical* to Eq. (5-127a), viz.

$$\text{Diffuse limit} \quad \overline{S_1 S_2} = \frac{A_1}{\left[ \frac{1}{\epsilon_1} + \left( \frac{A_1}{A_2} \right) \frac{\rho_2}{\epsilon_2} \right]} \quad (5-134b, 5-127a)$$

For the case of (infinite) parallel flat plates where  $A_1 = A_2$ , Eq. (5-134) leads to a general formula *similar* to Eq. (5-134a) but with the stipulation here that  $\epsilon_1 \equiv 1 - \rho_{D1} - \rho_{S1}$  and  $\epsilon_2 \equiv 1 - \rho_{D2} - \rho_{S2}$ .

Another particularly interesting limit of Eq. (5-134) occurs when  $A_2 \gg A_1$ , which might represent a small sphere irradiated by an infinite surroundings which can reflect radiation originating at  $A_1$  back to  $A_1$ . That is to say, even though  $A_2 \rightarrow \infty$ , the "self" total exchange area does not necessarily vanish, to wit

$$\overline{S_1 S_1} = \frac{\epsilon_1^2 \rho_{S2} \cdot A_1}{[1 - \rho_1 \cdot \rho_{S2}]} \quad \text{and} \quad \overline{S_1 S_2} = \frac{\epsilon_1 (1 - \rho_{S2}) \cdot A_1}{[1 - \rho_1 \cdot \rho_{S2}]} \quad (5-134c,d)$$

which again exhibit diffuse and specular limits. The diffuse plus specular reflection model becomes significantly more complex for geometries with  $M \geq 3$  where digital computation is usually required.

**An Exact Solution to the Integral Equations—The Hohlraum** Exact solutions of the fundamental *integral equations* for radiative transfer are available for only a few simple cases. One of these is the evaluation of the emittance from a small aperture, of area  $A_1$ , in the surface of an isothermal spherical cavity of radius  $R$ . In German, this geometry is termed a *hohlraum* or hollow space. For this special case the radiosity  $W$  is constant over the inner surface of the cavity. It then follows that the ratio  $W/E$  is given by

$$W/E = \frac{\epsilon}{1 - \rho [1 - A_1/(4\pi R^2)]} \quad (5-135)$$

where  $\epsilon$  and  $\rho = 1 - \epsilon$  are the diffuse emissivity and reflectivity of the interior cavity surface, respectively. The ratio  $W/E$  is the effective emittance of the aperture as sensed by an external narrow-angle receiver (radiometer) viewing the cavity interior. Assume that the cavity is constructed of a rough material whose (diffuse) emissivity is  $\epsilon = 0.5$ . As a point of reference, if the cavity is to simulate a blackbody emitter to better than 98 percent of an ideal theoretical blackbody, Eq. (5-135) then predicts that the ratio of the aperture to sphere areas  $A_1/(4\pi R^2)$  must be less than 2 percent. Equation (5-135) has practical utility in the experimental design of calibration standards for laboratory radiometers.

### RADIATION FROM GASES AND SUSPENDED PARTICULATE MATTER

**Introduction** Flame radiation originates as a result of emission from water vapor and carbon dioxide in the hot gaseous combustion

products and from the presence of particulate matter. The latter includes emission from burning of microscopic and submicroscopic soot particles, and from large suspended particles of coal, coke, or ash. Thermal radiation owing to the presence of water vapor and carbon dioxide is not visible. The characteristic blue color of clean natural gas flames is due to chemiluminescence of the excited intermediates in the flame which contribute negligibly to the radiation from combustion products.

**Gas Emissivities** Radiant transfer in a gaseous medium is characterized by three quantities; the gas emissivity, gas absorptivity, and gas transmissivity. Gas emissivity refers to radiation originating within a gas volume which is incident on some reference surface. Gas absorptivity and transmissivity, however, refer to the absorption and transmission of radiation from some *external* surface radiation source characterized by some radiation temperature  $T_1$ . The sum of the gas absorptivity and transmissivity must, by definition, be unity. Gas absorptivity may be calculated from an appropriate gas emissivity. The gas emissivity is a function only of the gas temperature  $T_g$  while the absorptivity and transmissivity are functions of both  $T_g$  and  $T_1$ .

The **standard hemispherical monochromatic gas emissivity** is defined as the direct volume-to-surface exchange area for a hemispherical gas volume to an infinitesimal area element located at the center of the planar base. Consider monochromatic transfer in a *black* hemispherical enclosure of radius  $R$  that confines an isothermal volume of gas at temperature  $T_g$ . The temperature of the bounding surfaces is  $T_1$ . Let  $A_2$  denote the area of the finite hemispherical surface and  $dA_1$  denote an infinitesimal element of area located at the center of the planar base. The (dimensionless) monochromatic direct exchange area for exchange between the finite hemispherical surface  $A_2$  and  $dA_1$  then follows from direct integration of Eq. (5-116a) as

$$\frac{\partial(\overline{s_1 s_2})_\lambda}{\partial A_1} = \int_{\phi_1=0}^{\pi/2} \frac{e^{-K_\lambda R}}{\pi R^2} \cos\phi_1 \, 2\pi R^2 \sin\phi_1 \, d\phi_1 = e^{-K_\lambda R} \quad (5-136a)$$

and from conservation there results

$$\frac{\partial(\overline{s_1 \overline{g}})_\lambda}{\partial A_1} = 1 - e^{-K_\lambda R} \quad (5-136b)$$

Note that Eq. (5-136b) is identical to the expression for the gas emissivity for a column of path length  $R$ . In Eqs. (5-136) the gas absorption coefficient is a function of gas temperature, composition, and wavelength, that is,  $K_\lambda = K_\lambda(T, \lambda)$ . The net monochromatic radiant flux density at  $dA_1$  due to irradiation from the gas volume is then given by

$$q_{1g,\lambda} = \frac{\partial(\overline{s_1 \overline{g}})_\lambda}{\partial A_1} (E_{1,\lambda} - E_{g,\lambda}) \equiv \alpha_{g,1,\lambda} E_{1,\lambda} - \epsilon_{g,\lambda} E_{g,\lambda} \quad (5-137)$$

In Eq. (5-137),  $\epsilon_{g,\lambda}(T, \lambda) = 1 - \exp(-K_\lambda R)$  is defined as the monochromatic or *spectral gas emissivity* and  $\alpha_{g,\lambda}(T, \lambda) = \epsilon_{g,\lambda}(T, \lambda)$ .

If Eq. (5-137) is integrated with respect to wavelength over the entire EM spectrum, an expression for the *total* flux density is obtained

$$q_{1g} = \alpha_{g,1} E_1 - \epsilon_g E_g \quad (5-138)$$

where 
$$\epsilon_g(T_g) = \int_{\lambda=0}^{\infty} \epsilon_\lambda(T_g, \lambda) \cdot \frac{E_{b,\lambda}(T_g, \lambda)}{E_b(T_g)} \, d\lambda \quad (5-138a)$$

and 
$$\alpha_{g,1}(T_1, T_g) = \int_{\lambda=0}^{\infty} \alpha_{g,\lambda}(T_g, \lambda) \cdot \frac{E_{b,\lambda}(T_1, \lambda)}{E_b(T_1)} \, d\lambda \quad (5-138b)$$

define the *total* gas emissivity and absorptivity, respectively. The notation used here is analogous to that used for surface emissivity and absorptivity as previously defined. For a *real* gas  $\epsilon_g = \alpha_{g,1}$  only if  $T_1 = T_g$ , while for a *gray* gas mass of arbitrarily shaped volume  $\epsilon_g = \alpha_{g,1} = \partial(\overline{s_1 \overline{g}})/\partial A_1$  is independent of temperature. Because  $K_\lambda(T, \lambda)$  is also a function of the composition of the radiating species, it is necessary in what follows to define a second absorption coefficient  $k_{p,\lambda}$ , where  $K_\lambda = k_{p,\lambda} p$ . Here  $p$  is the partial pressure of the radiating species, and  $k_{p,\lambda}$ , with units of  $(\text{atm}\cdot\text{m})^{-1}$ , is referred to as the *monochromatic line absorption coefficient*.

**Mean Beam Lengths** It is always possible to represent the emissivity of an arbitrarily shaped volume of gray gas (and thus the corre-

sponding direct gas-to-surface exchange area) with an equivalent sphere of radius  $\overline{R} = L_M$ . In this context the hemispherical radius  $R = L_M$  is referred to as the **mean beam length** of the arbitrary gas volume. Consider, e.g., an isothermal gas layer at temperature  $T_g$  confined by two infinite parallel plates separated by distance  $L$ . Direct integration of Eq. (5-116a) and use of conservation yield a closed-form expression for the requisite surface-gas direct exchange area

$$\frac{\partial(\overline{s_1 \overline{g}})}{\partial A_1} = [1 - 2E_3(KL)] \quad (5-139a)$$

where  $E_n(z) = \int_{t=1}^{\infty} \frac{e^{-zt}}{t^n} dt$  is defined as the ***n*th-order exponential**

**integral** which is readily available. Employing the definition of gas emissivity, the **mean beam length** between the plates  $L_M$  is then defined by the expression

$$\epsilon_g = [1 - 2E_3(KL)] \equiv 1 - e^{-KL_M} \quad (5-139b)$$

Solution of Eq. (5-139b) yields  $KL_M = -\ln[2E_3(KL)]$ , and it is apparent that  $KL_M$  is a function of  $KL$ . Since  $E_n(0) = 1/(n-1)$  for  $n > 1$ , the mean beam length approximation also correctly predicts the gas emissivity as zero when  $K = 0$  and  $K \rightarrow \infty$ .

In the limit  $K \rightarrow 0$ , power series expansion of both sides of the Eq. (5-139b) leads to  $KL_M \rightarrow 2KL \equiv KL_{M0}$ , where  $L_M \equiv L_{M0} = 2L$ . Here  $L_{M0}$  is defined as the **optically thin mean beam length** for radiant transfer from the entire *infinite* planar gas layer to a differential element of surface area on one of the plates. The optically thin mean beam length for two infinite parallel plates is thus simply *twice* the plate spacing  $L$ . In a similar manner it may be shown that for a sphere of diameter  $D$ ,  $L_{M0} = \frac{2}{3}D$ , and for an infinitely long cylinder  $L_{M0} = D$ . A useful default formula for an arbitrary enclosure of volume  $V$  and area  $A$  is given by  $L_{M0} = 4V/A$ . This expression predicts  $L_{M0} = \frac{2}{3}R$  for the standard hemisphere of radius  $R$  because the optically thin mean beam length is averaged over the *entire* hemispherical enclosure.

Use of the optically thin value of the mean beam length yields values of gas emissivities or exchange areas that are too high. It is thus necessary to introduce a dimensionless constant  $\beta \leq 1$  and define some new **average mean beam length** such that  $KL_M \equiv \beta KL_{M0}$ . For the case of parallel plates, we now require that the mean beam length exactly predict the gas emissivity for a *third* value of  $KL$ . In this example we find  $\beta = -\ln[2E_3(KL)]/2KL$  and for  $KL = 0.193095$  there results  $\beta = 0.880$ . The value  $\beta = 0.880$  is not wholly arbitrary. It also happens to minimize the error defined by the so-called shape correction factor  $\phi = [\partial(\overline{s_1 \overline{g}})/\partial A_1]/(1 - e^{-KL_M})$  for all  $KL > 0$ . The required *average* mean beam length for all  $KL > 0$  is then taken simply as  $L_M = 0.88L_{M0} = 1.76L$ . The error in this approximation is less than 5 percent.

For an arbitrary geometry, the average mean beam length is defined as the radius of a hemisphere of gas which predicts values of the direct exchange area  $\overline{s_1 \overline{g}}/A_1 = [1 - \exp(-KL_M)]$ , subject to the optimization condition indicated above. It has been found that the error introduced by using average mean beam lengths to approximate direct exchange areas is sufficiently small to be appropriate for many engineering calculations. When  $\beta = L_M/L_{M0}$  is evaluated for a large number of geometries, it is found that  $0.8 < \beta < 0.95$ . It is recommended here that  $\beta = 0.88$  be employed in lieu of any further geometric information. For a single-gas zone, all the requisite direct exchange areas can be approximated for engineering purposes in terms of a *single* appropriately defined average mean beam length.

**Emissivities of Combustion Products** Absorption or emission of radiation by the constituents of gaseous combustion products is determined primarily by vibrational and rotational transitions between the energy levels of the gaseous molecules. Changes in both vibrational and rotational energy states gives rise to *discrete* spectral lines. Rotational lines accompanying vibrational transitions usually overlap, forming a so-called vibration-rotation band. These bands are thus associated with the major vibrational frequencies of the molecules.

FIG. 5-21 Spectral emittances for carbon dioxide and water vapor after RADCAL.  $p_c L = p_w L = 0.36 \text{ atm}\cdot\text{m}$ ,  $T_g = 1500 \text{ K}$ .

Each spectral line is characterized by an absorption coefficient  $k_{p,\lambda}$  which exhibits a maximum at some central characteristic wavelength or wave number  $\eta_0 = 1/\lambda_0$  and is described by a Lorentz<sup>2</sup> probability distribution. Since the widths of spectral lines are dependent on collisions with other molecules, the absorption coefficient will also depend upon the composition of the combustion gases and the total system pressure. This brief discussion of gas spectroscopy is intended as an introduction to the factors controlling absorption coefficients and thus the factors which govern the empirical correlations to be presented for gas emissivities and absorptivities.

Figure 5-21 shows computed values of the spectral emissivity  $\epsilon_{g,\lambda} \equiv \epsilon_{g,\lambda}(T,pL,\lambda)$  as a function of wavelength for an equimolar mixture of carbon dioxide and water vapor for a gas temperature of 1500 K, partial pressure of 0.18 atm, and a path length  $L = 2 \text{ m}$ . Three principal absorption-emission bands for  $\text{CO}_2$  are seen to be centered on 2.7, 4.3, and 15  $\mu\text{m}$ . Two weaker bands at 2 and 9.7  $\mu\text{m}$  are also evident. Three principal absorption-emission bands for water vapor are also identified near 2.7, 6.6, and 20  $\mu\text{m}$  with lesser bands at 1.17, 1.36, and 1.87  $\mu\text{m}$ . The total emissivity  $\epsilon_g$  and absorptivity  $\alpha_{g,1}$  are calculated by integration with respect to wavelength of the spectral emissivities, using Eqs. (5-138) in a manner similar to the development of total surface properties.

**Spectral Emissivities** Highly resolved spectral emissivities can be generated at ambient temperatures from the HITRAN database (high-resolution transmission molecular absorption) that has been developed for atmospheric models [Rothman, L. S., Chance, K., and Goldman, A., eds., *J. Quant. Spectroscopy & Radiative Trans.*, **82** (1-4), 2003]. This database includes the chemical species:  $\text{H}_2\text{O}$ ,  $\text{CO}_2$ ,  $\text{O}_3$ ,  $\text{N}_2\text{O}$ ,  $\text{CO}$ ,  $\text{CH}_4$ ,  $\text{O}_2$ ,  $\text{NO}$ ,  $\text{SO}_2$ ,  $\text{NO}_2$ ,  $\text{NH}_3$ ,  $\text{HNO}_3$ ,  $\text{OH}$ ,  $\text{HF}$ ,  $\text{HCl}$ ,  $\text{HBr}$ ,  $\text{ClO}$ ,  $\text{OCS}$ ,  $\text{H}_2\text{CO}$ ,  $\text{HOCl}$ ,  $\text{N}_2$ ,  $\text{HCN}$ ,  $\text{CH}_3\text{C}$ ,  $\text{HCl}$ ,  $\text{H}_2\text{O}_2$ ,  $\text{C}_2\text{H}_2$ ,  $\text{C}_2\text{H}_6$ ,  $\text{PH}_3$ ,  $\text{COF}_2$ ,  $\text{SF}_6$ ,  $\text{H}_2\text{S}$ , and  $\text{HCO}_2\text{H}$ . These data have been extended to high temperature for  $\text{CO}_2$  and  $\text{H}_2\text{O}$ , allowing for the changes in the population of different energy levels and in the line half width [Denison, M. K., and Webb, B. W., *Heat Transfer*, **2**, 19-24 (1994)]. The resolution in the single-line models of emissivities is far greater than that needed in engineering calculations. A number of models are available that average the emissivities over narrow-wavelength regimes or over the entire band. An extensive set of measurements of narrowband parameters performed at NASA (Ludwig, C., et al., *Handbook of Infrared Radiation from Combustion Gases*, NASA SP-3080, 1973) has been used to develop the RADCAL computer code to obtain spectral emissivities for  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ ,  $\text{CH}_4$ ,  $\text{CO}$ , and soot (Grosshandler,

<sup>2</sup>Spectral lines are conventionally described in terms of wave number  $\eta = 1/\lambda$ , with each line having a peak absorption at wave number  $\eta_0$ . The Lorentz distribution is defined as  $k_{\eta}/S = \frac{b_c}{\pi[b_c^2 + (\eta - \eta_0)^2]}$  where  $S$  is the integral of  $k_{\eta}$  over all

wave numbers. The parameter  $S$  is known as the integrated line intensity, and  $b_c$  is defined as the collision line half-width, i.e., the half-width of the line is one-half of its peak centerline value. The units of  $k_{\eta}$  are  $\text{m}^{-1} \text{ atm}^{-1}$ .

W. L., "RADCAL," NIST Technical Note 1402, 1993). The exponential wideband model is available for emissions averaged over a band for  $\text{H}_2\text{O}$ ,  $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{CH}_4$ ,  $\text{NO}$ ,  $\text{SO}_2$ ,  $\text{N}_2\text{O}$ ,  $\text{NH}_3$ , and  $\text{C}_2\text{H}_2$  [Edwards, D. K., and Menard, W. A., *Appl. Optics*, **3**, 621-625 (1964)]. The line and band models have the advantages of being able to account for complexities in determining emissivities of line broadening due to changes in composition and pressure, exchange with spectrally selective walls, and greater accuracy in formulating fluxes in gases with temperature gradients. These models can be used to generate the total emissivities and absorptivities that will be used in this chapter. RADCAL is a command-line FORTRAN code which is available in the public domain on the Internet.

**Total Emissivities and Absorptivities** Total emissivities and absorptivities for water vapor and carbon dioxide at present are still based on data embodied in the classical **Hottel emissivity charts**. These data have been adjusted with the more recent measurements in RADCAL and used to develop the correlations of emissivities given in Table 5-5. Two empirical correlations which permit hand calculation of emissivities for water vapor, carbon dioxide, and four mixtures of the two gases are presented in Table 5-5. The first section of Table 5-5 provides data for the two constants  $b$  and  $n$  in the empirical relation

$$\overline{\epsilon_g T_g} = b[pL - 0.015]^n \quad (5-140a)$$

while the second section of Table 5-5 utilizes the four constants in the empirical correlation

$$\log(\overline{\epsilon_g T_g}) = a_0 + a_1 \log(pL) + a_2 \log^2(pL) + a_3 \log^3(pL) \quad (5-140b)$$

In both cases the empirical constants are given for the three temperatures of 1000, 1500, and 2000 K. Table 5-5 also includes some six values for the partial pressure ratios  $p_w/p_c$  of water vapor to carbon dioxide, namely, 0, 0.5, 1.0, 2.0, 3.0, and  $\infty$ . These ratios correspond to composition values of  $p_c/(p_c + p_w) = 1/(1 + p_w/p_c)$  of 0, 1/3, 1/2, 2/3, 3/4, and unity. For emissivity calculations at other temperatures and mixture compositions, linear interpolation of the constants is recommended.

The absorptivity can be obtained from the emissivity with aid of Table 5-5 by using the following functional equivalence.

$$\overline{\alpha_{g,1} T_1} = [\overline{\epsilon_g T_1}(pL \cdot T_1/T_g)] \left( \frac{T_g}{T_1} \right)^{0.5} \quad (5-141)$$

Verbally, the absorptivity computed from Eq. (5-141) by using the correlations in Table 5-5 is based on a value for gas emissivity  $\epsilon_g$  calculated at a temperature  $T_1$  and at a partial-pressure path-length product of  $(p_c + p_w)LT_1/T_g$ . The absorptivity is then equal to this value of gas emissivity multiplied by  $(T_g/T_1)^{0.5}$ . It is recommended that spectrally based models such as RADCAL (loc. cit.) be used particularly when extrapolating beyond the temperature, pressure, or partial-pressure-length product ranges presented in Table 5-5.

A comparison of the results of the predictions of Table 5-5 with values obtained via the integration of the spectral results calculated from the narrowband model in RADCAL is provided in Fig. 5-22. Here calculations are shown for  $p_c L = p_w L = 0.12 \text{ atm}\cdot\text{m}$  and a gas temperature of 1500 K. The RADCAL predictions are 20 percent higher than the measurements at low values of  $pL$  and are 5 percent higher at the large values of  $pL$ . An extensive comparison of different sources of emissivity data shows that disparities up to 20 percent are to be expected at the current time [Lallemant, N., Sayre, A., and Weber, R., *Prog. Energy Combust. Sci.*, **22**, 543-574, (1996)]. However, smaller errors result for the range of the total emissivity measurements presented in the Hottel emissivity tables. This is demonstrated in Example 11.

**Example 11: Calculations of Gas Emissivity and Absorptivity** Consider a slab of gas confined between two infinite parallel plates with a distance of separation of  $L = 1 \text{ m}$ . The gas pressure is 101.325 kPa (1 atm), and the gas temperature is 1500 K (2240°F). The gas is an equimolar mixture of  $\text{CO}_2$  and  $\text{H}_2\text{O}$ , each with a partial pressure of 12 kPa ( $p_c = p_w = 0.12 \text{ atm}$ ). The radiative flux to one of its bounding surfaces has been calculated by using RADCAL for two cases. For case (a) the flux to the bounding surface is 68.3  $\text{kW/m}^2$  when the emitting gas is backed by a black surface at an ambient temperature of 300 K (80°F). This (cold) back surface contributes less than 1 percent to the flux. In case (b), the flux is calculated as 106.2  $\text{kW/m}^2$  when the gas is backed by a black surface at a temperature of 1000 K (1340°F). In this example, gas emissivity and

NOTE:  $p_w/(p_w + p_c)$  of 1/3, 1/2, 2/3, and 3/4 may be used to cover the ranges 0.2–0.4, 0.4–0.6, 0.6–0.7, and 0.7–0.8, respectively, with a maximum error in  $\epsilon_g$  of 5 percent at  $pL = 6.5$  m-atm, less at lower  $pL$ 's. Linear interpolation reduces the error generally to less than 1 percent. Linear interpolation or extrapolation on  $T$  introduces an error generally below 2 percent, less than the accuracy of the original data.

**FIG. 5-22** Comparison of Hottel and RADCAL total gas emissivities. Equimolar gas mixture of CO<sub>2</sub> and H<sub>2</sub>O with  $p_c = p_w = 0.12$  atm and  $T_g = 1500$  K.

absorptivity are to be computed from these flux values and compared with values obtained by using Table 5-5.

Case (a): The flux incident on the surface is equal to  $\epsilon_g \sigma T_g^4 = 68.3 \text{ kW/m}^2$ ; therefore,  $\epsilon_g = 68,300 / (5.6704 \times 10^{-8} \cdot 1500^4) = 0.238$ . To utilize Table 5-5, the mean beam length for the gas is calculated from the relation  $L_M = 0.88 L_{M0} = 0.88 \cdot 2L = 1.76$  m. For  $T_g = 1500$  K and  $(p_c + p_w)L_M = 0.24(1.76) = 0.422$  atm-m, the two-constant correlation in Table 5-5 yields  $\epsilon_g = 0.230$  and the four-constant correlation yields  $\epsilon_g = 0.234$ . These results are clearly in excellent agreement with the predicted value of  $\epsilon_g = 0.238$  obtained from RADCAL.

Case (b): The flux incident on the surface ( $106.2 \text{ kW/m}^2$ ) is the sum of that contributed by (1) gas emission  $\epsilon_g \sigma T_g^4 = 68.3 \text{ kW/m}^2$  and (2) emission from the opposing surface corrected for absorption by the intervening gas using the gas transmissivity, that is,  $\tau_{g,1} \sigma T_1^4$  where  $\tau_{g,1} = 1 - \alpha_{g,1}$ . Therefore  $\alpha_{g,1} = [1 - (106,200 - 68,300) / (5.6704 \times 10^{-8} \cdot 1000^4)] = 0.332$ . Using Table 5-5, the two-constant and four-constant gas emissivities evaluated at  $T_1 = 1000$  K and  $pL = 0.4224(1000/1500) = 0.282$  atm-m are  $\epsilon_g = 0.2654$  and  $\epsilon_g = 0.2707$ , respectively. Multiplication by the factor  $(T_g/T_1)^{0.5} = (1500/1000)^{0.5} = 1.225$  produces the final values of the two corresponding gas absorptivities  $\alpha_{g,1} = 0.325$  and  $\alpha_{g,1} = 0.332$ , respectively. Again the agreement with RADCAL is excellent.

**Other Gases** The most extensive available data for gas emissivity are those for carbon dioxide and water vapor because of their importance in the radiation from the products of fossil fuel combustion. Selected data for other species present in combustion gases are provided in Table 5-6.

Flames and Particle Clouds

**Luminous Flames** Luminosity conventionally refers to soot radiation. At atmospheric pressure, soot is formed in locally fuel-rich portions of flames in amounts that usually correspond to less than 1 percent of the carbon in the fuel. Because soot particles are small relative to the wavelength of the radiation of interest in flames (primary particle diameters of soot are of the order of 20 nm compared to wavelengths of interest of 500 to 8000 nm), the incident radiation permeates the particles, and the absorption is proportional to the volume of the particles. In the limit of  $r_p/\lambda \ll 1$ , the Rayleigh limit, the monochromatic emissivity  $\epsilon_\lambda$  is given by

$$\epsilon_\lambda = 1 - \exp(-K \cdot f_v \cdot L/\lambda) \tag{5-142}$$

where  $f_v$  is the volumetric soot concentration,  $L$  is the path length in the same units as the wavelength  $\lambda$ , and  $K$  is dimensionless. The value  $K$  will vary with fuel type, experimental conditions, and the temperature history of the soot. The values of  $K$  for a wide range of systems are within a factor of about 2 of one another. The single most important variable governing the value of  $K$  is the hydrogen/carbon ratio of the soot, and the value of  $K$  increases as the H/C ratio decreases. A value of  $K = 9.9$  is recommended on the basis of seven studies involving 29 fuels [Mulholland, G. W., and Croarkin, C., *Fire and Materials*, **24**, 227–230 (2000)].

The total emissivity of soot  $\epsilon_s$  can be obtained by substituting  $\epsilon_\lambda$  from Eq. (5-142) for  $\epsilon_\lambda$  in Eq. (5-138a) to yield

$$\epsilon_s = \int_{\lambda=0}^{\infty} \epsilon_\lambda \frac{E_{b,\lambda}(T_g, \lambda)}{E_b(T_g)} d\lambda = 1 - \frac{15}{4} [\Psi^{(3)}(1 + K \cdot f_v \cdot L \cdot T/c_2)] \tag{5-143}$$

$$\cong (1 + K \cdot f_v \cdot L \cdot T/c_2)^{-4}$$

Here  $\Psi^{(3)}(x)$  is defined as the pentagamma function of  $x$  and  $c_2$  (m·K) is again Planck's second constant. The approximate relation in Eq. (5-143) is accurate to better than 1 percent for arguments yielding values of  $\epsilon_s < 0.7$ . At present, the largest uncertainty in estimating total soot emissivities is in the estimation of the soot volume fraction  $f_v$ . Soot forms in the fuel-rich zones of flames. Soot formation rates are a function of fuel type, mixing rate, local equivalence ratio  $\Phi$ , temperature, and pressure. The equivalence ratio is defined as the quotient of the actual to stoichiometric fuel-to-oxidant ratio  $\Phi = [F/O]_{Act}/[F/O]_{Stoich}$ . Soot formation increases with the aromaticity or C/H ratio of fuels with benzene,  $\alpha$ -methyl naphthalene, and acetylene having a high propensity to form soot and methane having a low soot formation propensity. Oxygenated fuels, such as alcohols, emit little soot. In practical turbulent diffusion flames, soot forms on the fuel side of the flame front. In premixed flames, at a given temperature, the rate of soot formation increases rapidly for  $\Phi > 2$ . For temperatures above

1500 K, soot burns out rapidly (in less than 0.1s) under fuel-lean conditions,  $\Phi < 1$ . Because of this rapid soot burnout, soot is usually localized in a relatively small fraction of a furnace or combustor volume. Long, poorly mixed diffusion flames promote soot formation while highly backmixed combustors can burn soot-free. In a typical flame at atmospheric pressure, maximum volumetric soot concentrations are found to be in the range  $10^{-7} < f_v < 10^{-6}$ . This corresponds to a soot formation of about 1.5 to 15 percent of the carbon in the fuel. When  $f_v$  is to be calculated at high pressures, allowance must be made for the significant increase in soot formation with pressure and for the inverse proportionality of  $f_v$  with respect to pressure. Great progress is being made in the ability to calculate soot in premixed flames. For example, predicted and measured soot concentration have been compared in a well-stirred reactor operated over a wide range of temperatures and equivalence ratios [Brown, N.J., Revzan, K. L., Frenklach, M., *Twenty-seventh Symposium (International) on Combustion*, pp. 1573–1580, 1998]. Moreover, CFD (computational fluid dynamics) and population dynamics modeling have been used to simulate soot formation in a turbulent non-premixed ethylene-air flame [Zucca, A., Marchisio, D. L., Barresi, A. A., Fox, R. O., *Chem. Eng. Sci.*, 2005]. The importance of soot radiation varies widely between combustors. In large boilers the soot is confined to small volumes and is of only local importance. In gas turbines, cooling the combustor liner is of primary importance so that only small incremental soot radiation is of concern. In high-temperature glass tanks, the presence of soot adds 0.1 to 0.2 to emissivities of oil-fired flames. In natural gas-fired flames, efforts to augment flame emissivities with soot generation have generally been unsuccessful. The contributions of soot to the radiation from pool fires often dominates, and thus the presence of soot in such flames directly impacts the safe separation distances from dikes around oil tanks and the location of flares with respect to oil rigs.

**Clouds of Large Black Particles** The emissivity  $\epsilon_M$  of a cloud of black particles with a large perimeter-to-wavelength ratio is

$$\epsilon_M = 1 - \exp[-(a/v)L] \tag{5-144}$$

where  $a/v$  is the projected area of the particles per unit volume of space. If the particles have no negative curvature (the particle does not "see" any of itself) and are randomly oriented,  $a = a'/4$ , where  $a'$  is the actual surface area. If the particles are uniform,  $a/v = cA = cA'/4$ , where  $A$  and  $A'$  are the projected and total areas of each particle and  $c$  is the number concentration of particles. For spherical particles this leads to

$$\epsilon_M = 1 - \exp[-(\pi/4)cd_p^2L] = 1 - \exp(-1.5f_vL/d_p) \tag{5-145}$$

As an example, consider a heavy fuel oil (CH<sub>1.5</sub>, specific gravity, 0.95) atomized to a mean surface particle diameter of  $d_p$  burned with

20 percent excess air to produce coke-residue particles having the original drop diameter and suspended in combustion products at 1204°C (2200°F). The flame emissivity due to the particles along a path of  $L$  m, with  $d_p$  measured in micrometers, is

$$\epsilon_M = 1 - \exp(-24.3L/d_p) \quad (5-146)$$

For 200- $\mu\text{m}$  particles and  $L = 3.05$  m, the particle contribution to emissivity is calculated as 0.31.

**Clouds of Nonblack Particles** For nonblack particles, emissivity calculations are complicated by multiple scatter of the radiation reflected by each particle. The emissivity  $\epsilon_M$  of a cloud of gray particles of individual emissivity  $\epsilon_1$  can be estimated by the use of a simple modification Eq. (5-144), i.e.,

$$\epsilon_M = 1 - \exp[-\epsilon_1(a/v)L] \quad (5-147)$$

Equation (5-147) predicts that  $\epsilon_M \rightarrow 1$  as  $L \rightarrow \infty$ . This is *impossible* in a scattering system, and use of Eq. (5-147) is restricted to values of the optical thickness  $(a/v)L < 2$ . Instead, the asymptotic value of  $\epsilon_M$  is obtained from Fig. 5-12 as  $\epsilon_M = \epsilon_b$  ( $\lim L \rightarrow \infty$ ), where the albedo  $\omega$  is replaced by the particle-surface reflectance  $\omega = 1 - \epsilon_1$ . Particles with perimeter-to-wavelength ratios of 0.5 to 5.0 can be analyzed, with significant mathematical complexity, by use of the *Mie equations* (Bohren, C. F., and Huffman, D. R., *Absorption and Scattering of Light by Small Particles*, Wiley, 1998).

**Combined Gas, Soot, and Particulate Emission** In a mixture of emitting species, the emission of each constituent is attenuated on its way to the system boundary by absorption by all other constituents. The transmissivity of a mixture is the product of the transmissivities of its component parts. This statement is a corollary of Beer's law. For present purposes, the transmissivity of "species  $k$ " is defined as  $\tau_k = 1 - \epsilon_k$ . For a mixture of combustion products consisting of carbon dioxide, water vapor, soot, and oil coke or char particles, the total emissivity  $\epsilon_T$  at any wavelength can therefore be obtained from

$$(1 - \epsilon_T)_\lambda = (1 - \epsilon_C)_\lambda(1 - \epsilon_W)_\lambda(1 - \epsilon_S)_\lambda(1 - \epsilon_M)_\lambda \quad (5-148)$$

where the subscripts denote the four flame species. The total emissivity is then obtained by integrating Eq. (5-148) over the entire EM energy spectrum, taking into account the variability of  $\epsilon_C$ ,  $\epsilon_W$ , and  $\epsilon_S$  with respect to wavelength. In Eq. (5-148),  $\epsilon_M$  is independent of wavelength because absorbing char or coke particles are effectively black-body absorbers. Computer programs for spectral emissivity, such as RADCAL (loc. cit.), perform the integration with respect to wavelength for obtaining total emissivity. Corrections for the overlap of vibration-rotation bands of  $\text{CO}_2$  and  $\text{H}_2\text{O}$  are automatically included in the correlations for  $\epsilon_g$  for mixtures of these gases. The monochromatic soot emissivity is higher at shorter wavelengths, resulting in higher attenuations of the bands at 2.7  $\mu\text{m}$  for  $\text{CO}_2$  and  $\text{H}_2\text{O}$  than at longer wavelengths. The following equation is recommended for calculating the emissivity  $\epsilon_{g+s}$  of a mixture of  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ , and soot

$$\epsilon_{g+s} = \epsilon_g + \epsilon_s - M \cdot \epsilon_g \epsilon_s \quad (5-149)$$

where  $M$  can be represented with acceptable error by the dimensionless function

$$M = 1.12 - 0.27 \cdot (T/1000) + 2.7 \times 10^{-5} f_p \cdot L \quad (5-150)$$

In Eq. (5-150),  $T$  has units of kelvins and  $L$  is measured in meters. Since coke or char emissivities are gray, their addition to those of the  $\text{CO}_2$ ,  $\text{H}_2\text{O}$ , and soot follows simply from Eq. (5-148) as

$$\epsilon_T = \epsilon_{g+s} + \epsilon_M - \epsilon_{g+s} \epsilon_M \quad (5-151)$$

with the definition  $1 - \epsilon_{g+s} \equiv (1 - \epsilon_C)(1 - \epsilon_W)(1 - \epsilon_S)$ .

## RADIATIVE EXCHANGE WITH PARTICIPATING MEDIA

**Energy Balances for Volume Zones—The Radiation Source Term** Reconsider a generalized enclosure with  $N$  volume zones confining a *gray* gas. When the  $N$  gas temperatures are *unknown*, an *additional* set of  $N$  equations is required in the form of radiant energy

balances for each volume zone. These  $N$  equations are given by the *definition* of the  $N$ -vector for the **net radiant volume absorption**  $\mathbf{S}' = [S'_j]$  for each volume zone

$$\mathbf{S}' = \overline{\mathbf{GS}} \cdot \mathbf{E} + \overline{\mathbf{GG}} \cdot \mathbf{E}_g - 4K\mathbf{VI} \cdot \mathbf{E}_g \quad [N \times 1] \quad (5-152)$$

The radiative source term is a discretized formulation of the *net radiant absorption* for each volume zone which may be incorporated as a *source term* into numerical approximations for the generalized *energy equation*. As such, it permits formulation of energy balances on each zone that may include conductive and convective heat transfer. For  $K \rightarrow 0$ ,  $\overline{\mathbf{GS}} \rightarrow 0$ , and  $\overline{\mathbf{GG}} \rightarrow 0$  leading to  $\mathbf{S}' \rightarrow \mathbf{0}_N$ . When  $K \neq 0$  and  $\mathbf{S}' = \mathbf{0}_N$ , the gas is said to be in a state of *radiative equilibrium*. In the notation usually associated with the discrete ordinate (DO) and finite volume (FV) methods, see Modest (op. cit., Chap. 16), one would write  $S'_j/V_j = K[G - 4E_g] = -\nabla \cdot \vec{q}_r$ . Here  $H_g = G/4$  is the average flux density incident on a given volume zone from all other surface and volume zones. The DO and FV methods are currently available options as "RTE-solvers" in complex simulations of combustion systems using *computational fluid dynamics* (CFD).<sup>o</sup>

Implementation of Eq. (5-152) necessitates the definition of two additional *symmetric*  $N \times N$  arrays of exchange areas, namely,  $\overline{\mathbf{gg}} = [\overline{g_i g_j}]$  and  $\overline{\mathbf{GG}} = [G_i G_j]$ . In Eq. (5-152)  $\mathbf{VI} = [V_j \delta_{ij}]$  is an  $N \times N$  diagonal matrix of zone volumes. The total exchange areas in Eq. (5-151) are *explicit* functions of the direct exchange areas as follows:

$$\text{Surface-to-gas exchange} \quad \overline{\mathbf{GS}} = \overline{\mathbf{SG}}^T \quad [N \times M] \quad (5-153a)$$

$$\text{Gas-to-gas exchange} \quad \overline{\mathbf{GG}} = \overline{\mathbf{gg}} + \overline{\mathbf{sg}} \cdot \rho \mathbf{I} \cdot \overline{\mathbf{Rg}} \quad [N \times M] \quad (5-153b)$$

The matrices  $\overline{\mathbf{gg}} = [\overline{g_i g_j}]$  and  $\overline{\mathbf{GG}} = [G_i G_j]$  must also satisfy the following **matrix conservation relations**:

$$\text{Direct exchange areas:} \quad 4K\mathbf{VI} \cdot \mathbf{1}_N = \overline{\mathbf{gs}} \cdot \mathbf{1}_M + \overline{\mathbf{gg}} \cdot \mathbf{1}_N \quad (5-154a)$$

$$\text{Total exchange areas:} \quad 4K\mathbf{VI} \cdot \mathbf{1}_N = \overline{\mathbf{GS}} \cdot \mathbf{1}_M + \overline{\mathbf{GG}} \cdot \mathbf{1}_N \quad (5-154b)$$

The formal integral definition of the direct gas-gas exchange area is

$$\overline{g_i g_j} = \iiint_{V_i} \iiint_{V_j} K^2 \frac{e^{-K_r}}{\pi^2} dV_j dV_i \quad (5-155)$$

Clearly, when  $K = 0$ , the two direct exchange areas involving a gas zone  $\overline{\mathbf{gs}}_i$  and  $\overline{\mathbf{gs}}_j$  vanish. Computationally it is *never* necessary to make resort to Eq. (5-155) for calculation of  $\overline{g_i g_j}$ . This is so because  $\overline{s_i g_j}$ ,  $\overline{g_i s_j}$ , and  $\overline{g_i g_j}$  may *all* be calculated *arithmetically* from appropriate values of  $\overline{s_i s_j}$  by using associated conservation relations and view factor algebra.

**Weighted Sum of Gray Gas (WSGG) Spectral Model** Even in simple engineering calculations, the assumption of a gray gas is almost never a good one. The zone method is now further generalized to make allowance for nongray radiative transfer via incorporation of the **weighted sum of gray gas** (WSGG) spectral model. Hottel has shown that the emissivity  $\epsilon_g(T, L)$  of an absorbing-emitting gas mixture containing  $\text{CO}_2$  and  $\text{H}_2\text{O}$  of known composition can be approximated by a *weighted sum of  $P$  gray gases*

$$\epsilon_g(T, L) \approx \sum_{p=1}^P a_p(T)(1 - e^{-K_p L}) \quad (5-156a)$$

where

$$\sum_{p=1}^P a_p(T) = 1.0 \quad (5-156b)$$

In Eqs. (5-156),  $K_p$  is some gray gas absorption coefficient and  $L$  is some appropriate path length. In practice, Eqs. (5-156) usually yield acceptable accuracy for  $P \leq 3$ . For  $P = 1$ , Eqs. (5-156) degenerate to the case of a single gray gas.

<sup>o</sup>To further clarify the mathematical differences between zoning and the DO and FV methods recognize that (neglecting scatter) the matrix expressions  $\mathbf{H} = \mathbf{AI}^{-1} \cdot \overline{\mathbf{ss}} \cdot \mathbf{W} + \mathbf{AI}^{-1} \cdot \overline{\mathbf{sg}} \cdot \mathbf{E}_g$  and  $4K \cdot \mathbf{H}_g = \mathbf{VI}^{-1} \cdot \overline{\mathbf{gs}} \cdot \mathbf{W} + \mathbf{VI}^{-1} \cdot \overline{\mathbf{gg}} \cdot \mathbf{E}_g$  represent spatial discretizations of the integral form(s) of the RTE applied at any point (zone) on the boundary or interior of an enclosure, respectively, for a gray gas.

**The Clear plus Gray Gas WSGG Spectral Model** In principle, the emissivity of all gases approaches unity for infinite path length  $L$ . In practice, however, the gas emissivity may fall considerably short of unity for representative values of  $pL$ . This behavior results because of the *band* nature of real gas spectral absorption and emission whereby there is usually no significant overlap between dominant absorption bands. Mathematically, this physical phenomenon is modeled by defining one of the gray gas components in the WSGG spectral model to be *transparent*.

For  $P = 2$  and path length  $L_M$ , Eqs. (5-156) yield the following expression for the gas emissivity

$$\epsilon_g = a_1(1 - e^{-K_1 L_M}) + a_2(1 - e^{-K_2 L_M}) \quad (5-157)$$

In Eq. (5-157) if  $K_1 = 0$  and  $a_2 \neq 0$ , the limiting value of gas emissivity is  $\epsilon_g(T, \infty) \rightarrow a_2$ . Put  $K_1 = 0$  in Eq. (5-157),  $a_g = a_2$ , and define  $\tau_g = e^{-K_2 L_M}$  as the gray gas transmissivity. Equation (5-157) then simplifies to

$$\epsilon_g = a_g(1 - \tau_g) \quad (5-158)$$

It is important to note in Eq. (5-158) that  $0 \leq a_g, \tau_g \leq 1.0$  while  $0 \leq \epsilon_g \leq a_g$ .

Equation (5-158) constitutes a two-parameter model which may be fitted with only *two* empirical emissivity data points. To obtain the constants  $a_g$  and  $\tau_g$  in Eq. (5-158) at fixed composition and temperature, denote the two emissivity data points as  $\epsilon_{g,2} = \epsilon_g(2pL) > \epsilon_{g,1} = \epsilon_g(pL)$  and recognize that  $\epsilon_{g,1} = a_g(1 - \tau_g)$  and  $\epsilon_{g,2} = a_g(1 - \tau_g^2) = a_g(1 - \tau_g)(1 + \tau_g) = \epsilon_{g,1}(1 + \tau_g)$ . These relations lead directly to the final emissivity fitting equations

$$\tau_g = \frac{\epsilon_{g,2}}{\epsilon_{g,1}} - 1 \quad (5-159a)$$

and

$$a_g = \frac{\epsilon_{g,1}}{2 - \epsilon_{g,2}/\epsilon_{g,1}} \quad (5-159b)$$

The clear plus gray WSGG spectral model also readily leads to values for gas *absorptivity* and *transmissivity*, with respect to some appropriate surface radiation source at temperature  $T_1$ , for example,

$$\alpha_{g,1} = a_{g,1}(1 - \tau_g) \quad (5-160a)$$

and

$$\tau_{g,1} = a_{g,1} \tau_g \quad (5-160b)$$

In Eqs. (5-160) the *gray* gas transmissivity  $\tau_g$  is taken to be identical to that obtained for the gas emissivity  $\epsilon_g$ . The constant  $a_{g,1}$  in Eq. (5-160a) is then obtained with knowledge of *one additional empirical value* for  $\alpha_{g,1}$  which may also be obtained from the correlations in Table 5-5. Notice further in the definitions of the three parameters  $\epsilon_g$ ,  $\alpha_{g,1}$ , and  $\tau_{g,1}$  that *all* the temperature dependence is forced into the *two* WSGG constants  $a_g$  and  $a_{g,1}$ .

The *three* clear plus gray WSGG constants  $a_g$ ,  $a_{g,1}$ , and  $\tau_g$  are functions of total pressure, temperature, and mixture composition. It is not necessary to ascribe any particular physical significance to them. Rather, they may simply be visualized as three constants that happen to fit the gas emissivity data. It is noteworthy that *three* constants are far fewer than the number required to calculate gas emissivity data from fundamental spectroscopic data. The two constants  $a_g$  and  $a_{g,1}$  defined in Eqs. (5-158) and (5-160) can, however, be interpreted *physically* in a particularly simple manner. Suppose the gas absorption spectrum is idealized by *many* absorption bands (boxes), *all* of which are characterized by the *identical* absorption coefficient  $K$ . The  $a$ 's might then be calculated from the total blackbody energy fraction  $F_b(\lambda T)$  defined in Eqs. (5-105) and (5-106). That is,  $a_g$  simply represents the total *energy fraction* of the blackbody energy distribution in which the gas *absorbs*. This concept may be further generalized to real gas absorption spectra via the *wideband stepwise gray spectral box model* (Modest, op. cit., Chap. 14).

When  $P \geq 3$ , exponential curve-fitting procedures for the WSGG spectral model become significantly more difficult for hand computation but are quite routine with the aid of a variety of readily available

mathematical software utilities. The clear plus gray WSGG fitting procedure is demonstrated in Example 8.

**The Zone Method and Directed Exchange Areas** Spectral dependence of real gas spectral properties is now introduced into the zone method via the WSGG spectral model. It is still assumed, however, that all surface zones are gray isotropic emitters and absorbers.

**General Matrix Representation** We first define a new set of four **directed exchange areas**  $\overleftarrow{\mathbf{SS}}$ ,  $\overleftarrow{\mathbf{SG}}$ ,  $\overleftarrow{\mathbf{GS}}$ , and  $\overleftarrow{\mathbf{GG}}$  which are denoted by an overarrow. The directed exchange areas are obtained from the total exchange areas for gray gases by simple matrix multiplication using weighting factors derived from the WSGG spectral model. The directed exchange areas are denoted by an overarrow to indicate the "sending" and "receiving" zone. The  $a$ -weighting factors for transfer originating at a gas zone  $a_{g,i}$  are derived from WSGG gas *emissivity* calculations, while those for transfers originating at a surface zone,  $a_i$  are derived from appropriate WSGG gas *absorptivity* calculations. Let  $\mathbf{agI}_p = [a_{p,g} \delta_{ij}]$  and  $\mathbf{aI}_p = [a_{p,i} \delta_{ij}]$  represent the  $P$  [ $M \times M$ ] and [ $N \times N$ ] *diagonal* matrices comprised of the appropriate WSGG  $a$  constants. The *directed* exchange areas are then computed from the associated *total* gray gas exchange areas via simple *diagonal* matrix multiplication.

$$\overleftarrow{\mathbf{SS}} = \sum_{p=1}^P \overleftarrow{\mathbf{SS}}_p \cdot \mathbf{aI}_p \quad [M \times M] \quad (5-161a)$$

$$\overleftarrow{\mathbf{SG}} = \sum_{p=1}^P \overleftarrow{\mathbf{SG}}_p \cdot \mathbf{aI}_p \quad [M \times N] \quad (5-161b)$$

$$\overleftarrow{\mathbf{GS}} = \sum_{p=1}^P \overleftarrow{\mathbf{GS}}_p \cdot \mathbf{aI}_p \quad [M \times N] \quad (5-161c)$$

$$\overleftarrow{\mathbf{GG}} = \sum_{p=1}^P \overleftarrow{\mathbf{GG}}_p \cdot \mathbf{aI}_p \quad [N \times N] \quad (5-161d)$$

$$\text{with} \quad \overleftarrow{\mathbf{KI}} = \sum_{p=1}^P \overleftarrow{\mathbf{KI}}_p \cdot \mathbf{aI}_p \quad [N \times N] \quad (5-161e)$$

In contrast to the *total* exchange areas which are always independent of temperature, the four *directed* arrays  $\overleftarrow{\mathbf{SS}}$ ,  $\overleftarrow{\mathbf{SG}}$ ,  $\overleftarrow{\mathbf{GS}}$ , and  $\overleftarrow{\mathbf{GG}}$  are dependent on the temperatures of each and every zone, i.e., as in  $a_{p,i} = a_p(T_i)$ . Moreover, in contrast to *total* exchange areas, the *directed* arrays  $\overleftarrow{\mathbf{SS}}$  and  $\overleftarrow{\mathbf{GG}}$  are generally not symmetric and  $\overleftarrow{\mathbf{GS}} \neq \overleftarrow{\mathbf{SG}}^T$ . Finally, since the directed exchange areas are temperature-*dependent*, iteration may be required to update the  $\mathbf{aI}_p$  and  $\mathbf{a}_g \mathbf{I}_p$  arrays during the course of a calculation. There is a great deal of latitude with regard to fitting the WSGG  $a$  constants in these matrix equations, especially if  $N > 1$  and composition variations are to be allowed for in the gas. An extensive discussion of  $a$  fitting for  $N > 1$  is beyond the scope of this presentation. Details of the fitting procedure, however, are presented in Example 12 in the context of a single-gas zone.

Having formulated the directed exchange areas, the governing matrix equations for the radiative flux equations at each surface zone and the radiant source term are then given as follows:

$$\mathbf{Q} = \epsilon \mathbf{AI} \cdot \mathbf{E} - \overleftarrow{\mathbf{SS}} \cdot \mathbf{E} - \overleftarrow{\mathbf{SG}} \cdot \mathbf{E}_g \quad (5-162a)$$

$$\mathbf{S}' = \overleftarrow{\mathbf{GG}} \cdot \mathbf{E}_g + \overleftarrow{\mathbf{GS}} \cdot \mathbf{E} - \overleftarrow{\mathbf{KI}} \cdot \mathbf{VI} \cdot \mathbf{E}_g \quad (5-162b)$$

or the alternative forms

$$\mathbf{Q} = [\mathbf{EI} \cdot \overleftarrow{\mathbf{SS}} - \overleftarrow{\mathbf{SS}} \cdot \mathbf{EI}] \cdot \mathbf{I}_M + [\mathbf{EI} \cdot \overleftarrow{\mathbf{SG}} - \overleftarrow{\mathbf{SG}} \cdot \mathbf{E}_g \mathbf{I}] \cdot \mathbf{I}_N \quad (5-163a)$$

$$\mathbf{S}' = -[\mathbf{E}_g \mathbf{I} \cdot \overleftarrow{\mathbf{GS}} - \overleftarrow{\mathbf{GS}} \cdot \mathbf{EI}] \cdot \mathbf{I}_M - [\mathbf{E}_g \mathbf{I} \cdot \overleftarrow{\mathbf{GG}} - \overleftarrow{\mathbf{GG}} \cdot \mathbf{E}_g \mathbf{I}] \cdot \mathbf{I}_N \quad (5-163b)$$

It may be *proved* that the  $\mathbf{Q}$  and  $\mathbf{S}'$  vectors computed from Eqs. (5-162) and (5-163) always *exactly* satisfy the overall (scalar) *radiant* energy balance  $\mathbf{I}_M^T \cdot \mathbf{Q} = \mathbf{I}_N^T \cdot \mathbf{S}'$ . In words, the total radiant gas emission for all gas zones in the enclosure must always exactly equal the total radiant energy received at all surface zones which comprise the enclosure. In Eqs. (5-162) and (5-163), the following definitions are employed for the *four forward-directed* exchange areas

$$\overleftarrow{\mathbf{SS}} = \overleftarrow{\mathbf{SS}}^T \quad \overleftarrow{\mathbf{SG}} = \overleftarrow{\mathbf{GS}}^T \quad \overleftarrow{\mathbf{GS}} = \overleftarrow{\mathbf{SG}}^T \quad \overleftarrow{\mathbf{GG}} = \overleftarrow{\mathbf{GG}}^T \quad (5-64a,b,c,d)$$

such that formally there are some *eight* matrices of directed exchange areas. The four *backward-directed* arrays of directed exchange areas must satisfy the following conservation relations

$$\overleftarrow{\mathbf{SS}} \cdot \mathbf{I}_M + \overleftarrow{\mathbf{SG}} \cdot \mathbf{I}_N = \varepsilon \mathbf{I} \cdot \mathbf{AI} \cdot \mathbf{I}_M \quad (5-165a)$$

$$4\overleftarrow{\mathbf{KI}} \cdot \mathbf{VI} \cdot \mathbf{I}_N = \overleftarrow{\mathbf{GS}} \cdot \mathbf{I}_M + \overleftarrow{\mathbf{GG}} \cdot \mathbf{I}_N \quad (5-165b)$$

Subject to the restrictions of no scatter and diffuse surface emission and reflection, the above equations are the most general matrix statement possible for the zone method. When  $P = 1$ , the *directed* exchange areas all reduce to the *total* exchange areas for a single gray gas. If, in addition,  $K = 0$ , the much simpler case of radiative transfer in a transparent medium results. If, in addition, all surface zones are *black*, the direct, total, and directed exchange areas are all identical.

**Allowance for Flux Zones** As in the case of a transparent medium, we now distinguish between source and flux surface zones. Let  $M = M_s + M_f$  represent the total number of surface zones where  $M_s$  is the number of source-sink zones and  $M_f$  is the number of flux zones. The flux zones are the *last to be numbered*. To accomplish this, partition the

surface emissive power and flux vectors as  $\mathbf{E} = \begin{bmatrix} \mathbf{E}_1 \\ \mathbf{E}_2 \end{bmatrix}$  and  $\mathbf{Q} = \begin{bmatrix} \mathbf{Q}_1 \\ \mathbf{Q}_2 \end{bmatrix}$ ,

where the subscript 1 denotes surface source/sink zones whose emissive power  $\mathbf{E}_1$  is specified a priori, and subscript 2 denotes surface flux zones of unknown emissive power vector  $\mathbf{E}_2$  and known radiative flux vector  $\mathbf{Q}_2$ . Suppose the radiative source vector  $\mathbf{S}'$  is *known*. Appropriate partitioning of Eqs. (5-162) then produces

$$\begin{bmatrix} \mathbf{Q}_1 \\ \mathbf{Q}_2 \end{bmatrix} = \begin{bmatrix} \varepsilon \mathbf{AI}_{1,1} & \mathbf{0} \\ \mathbf{0} & \varepsilon \mathbf{AI}_{2,2} \end{bmatrix} \cdot \begin{bmatrix} \mathbf{E}_1 \\ \mathbf{E}_2 \end{bmatrix} + \begin{bmatrix} \overleftarrow{\mathbf{SS}}_{1,2} & \overleftarrow{\mathbf{SS}}_{1,2} \\ \overleftarrow{\mathbf{SS}}_{2,1} & \overleftarrow{\mathbf{SS}}_{2,2} \end{bmatrix} \cdot \begin{bmatrix} \mathbf{E}_1 \\ \mathbf{E}_2 \end{bmatrix} - \begin{bmatrix} \overleftarrow{\mathbf{SG}} \\ \overleftarrow{\mathbf{SG}} \end{bmatrix} \cdot \mathbf{E}_g \quad (5-166a)$$

and

$$\mathbf{S}' = \overleftarrow{\mathbf{GG}} \cdot \mathbf{E}_g + \begin{bmatrix} \overleftarrow{\mathbf{GS}}_1 & \overleftarrow{\mathbf{GS}}_2 \end{bmatrix} \begin{bmatrix} \mathbf{E}_1 \\ \mathbf{E}_2 \end{bmatrix} - 4\overleftarrow{\mathbf{KI}} \cdot \mathbf{VI} \cdot \mathbf{E}_g \quad (5-166b)$$

where the definitions of the matrix partitions follow the conventions with respect to Eq. (5-120). Simultaneous solution of the *two* unknown vectors in Eqs. (5-166) then yields

$$\mathbf{E}_2 = \mathbf{RP} \cdot \begin{bmatrix} \overleftarrow{\mathbf{SS}}_{2,1} + \overleftarrow{\mathbf{SG}}_2 \cdot \mathbf{PP} \cdot \overleftarrow{\mathbf{GS}}_1 \\ \overleftarrow{\mathbf{SS}}_{2,2} \end{bmatrix} \cdot \mathbf{E}_1 + \mathbf{RP} \cdot \begin{bmatrix} \mathbf{Q}_2 - \overleftarrow{\mathbf{SG}}_2 \cdot \mathbf{PP} \cdot \mathbf{S}' \end{bmatrix} \quad (5-167a)$$

and

$$\mathbf{E}_g = \mathbf{PP} \cdot \begin{bmatrix} \overleftarrow{\mathbf{GS}}_1 & \overleftarrow{\mathbf{GS}}_2 \end{bmatrix} \begin{bmatrix} \mathbf{E}_1 \\ \mathbf{E}_2 \end{bmatrix} - \mathbf{PP} \cdot \mathbf{S}' \quad (5-167b)$$

where two auxiliary inverse matrices  $\mathbf{RP}$  and  $\mathbf{PP}$  are defined as

$$\mathbf{PP} = [4\overleftarrow{\mathbf{KI}} \cdot \mathbf{VI} - \overleftarrow{\mathbf{GG}}]^{-1} \quad (5-168a)$$

$$\mathbf{RP} = [\varepsilon \mathbf{AI}_{2,2} - \overleftarrow{\mathbf{SS}}_{2,2} - \overleftarrow{\mathbf{SG}}_2 \cdot \mathbf{PP} \cdot \overleftarrow{\mathbf{GS}}_2]^{-1} \quad (5-168b)$$

The emissive power vectors  $\mathbf{E}$  and  $\mathbf{E}_g$  are then both *known* quantities for purposes of subsequent calculation.

**Algebraic Formulas for a Single Gas Zone** As shown in Fig. 5-10, the three-zone system with  $M = 2$  and  $N = 1$  can be employed to simulate a surprisingly large number of useful engineering geometries. These include two infinite parallel plates confining an absorbing-emitting medium; *any* two-surface zone system where a nonconvex surface zone is completely surrounded by a second zone (this includes concentric spheres and cylinders), and the speckled two-surface enclosure. As in the case of a transparent medium, the inverse reflectivity matrix  $\mathbf{R}$  is capable of explicit matrix inversion for  $M = 2$ . This allows derivation of *explicit* algebraic equations for all the required *directed* exchange areas for the clear plus gray WSGG spectral model with  $M = 1$  and 2 and  $N = 1$ .

**The Limiting Case  $M = 1$  and  $N = 1$**  The directed exchange areas for this special case correspond to a single well-mixed gas zone completely surrounded by a single surface zone  $A_1$ . Here the reflectivity matrix is a  $1 \times 1$  scalar quantity which follows directly from the

general matrix equations as  $\mathbf{R} = [1/(A_1 - \overline{s_1 s_1} \cdot \rho_1)]$ . There are *two* WSGG clear plus gray constants  $a_1$  and  $a_g$ , and only *one* unique directed exchange area which satisfies the conservation relation  $\overline{s_1 s_1} + \overline{s_1 g} = A_1$ . The only two physically meaningful directed exchange areas are those between the surface zone  $A_1$  and the gas zone

$$\overleftarrow{S_1 G} = \frac{a_g \cdot \varepsilon_1 A_1 \cdot \overline{s_1 g}}{\varepsilon_1 \cdot A_1 + \rho_1 \cdot \overline{s_1 g}} \quad (5-169a)$$

$$\overleftarrow{G S_1} = \frac{a_1 \cdot \varepsilon_1 A_1 \cdot \overline{s_1 g}}{\varepsilon_1 \cdot A_1 + \rho_1 \cdot \overline{s_1 g}} \quad (5-169b)$$

The total radiative flux  $Q_1$  at surface  $A_1$  and the radiative source term  $Q_1 = S$  are given by

$$Q_1 = \overleftarrow{G S_1} \cdot E_1 - \overleftarrow{S_1 G} \cdot E_g \quad (5-169)$$

**Directed Exchange Areas for  $M = 2$  and  $N = 1$**  For this case there are *four* WSGG constants, i.e.,  $a_1$ ,  $a_2$ ,  $a_g$ , and  $\tau_g$ . There is one required value of  $K$  that is readily obtained from the equation  $K = -\ln(\tau_g)/L_{0g}$ , where  $\tau_g = \exp(-KL_{0g})$ . For an enclosure with  $M = 2$ ,  $N = 1$ , and  $K \neq 0$ , only *three* unique direct exchange areas are required because conservation stipulates  $A_1 = \overline{s_1 s_2} + \overline{s_1 s_2} + \overline{s_1 g}$  and  $A_2 = \overline{s_1 s_2} + \overline{s_2 s_2} + \overline{s_2 g}$ . For  $M = 2$  and  $N = 1$ , the matrix Eqs. (5-118) readily lead to the *general* gray gas matrix solution for  $\overleftarrow{\mathbf{SS}}$  and  $\overleftarrow{\mathbf{SG}}$  with  $K \neq 0$  as

$$\overleftarrow{\mathbf{SS}} = \begin{bmatrix} \varepsilon_1 A_1 - \overline{S_1 S_2} - \overline{S_1 G} & \overline{S_1 S_2} \\ \overline{S_1 S_1} & \varepsilon_2 A_2 - \overline{S_1 S_2} - \overline{S_2 G} \end{bmatrix} \quad (5-170a)$$

where

$$\overline{S_1 S_2} = \varepsilon_1 \varepsilon_2 A_1 A_2 \overline{s_1 s_2} / \det \mathbf{R}^{-1} \quad (5-170b)$$

$$\text{and } \overleftarrow{\mathbf{SG}} = \begin{bmatrix} \varepsilon_1 A_1 [(A_2 - \rho_2 \cdot \overline{s_2 s_2}) \cdot \overline{s_1 g} + \rho_2 \cdot \overline{s_1 s_2} \cdot \overline{s_2 g}] \\ \varepsilon_2 A_2 [(A_1 - \rho_1 \cdot \overline{s_1 s_1}) \cdot \overline{s_2 g} + \rho_1 \cdot \overline{s_1 s_2} \cdot \overline{s_1 g}] \end{bmatrix} / \det \mathbf{R}^{-1} \quad (5-170c)$$

with  $\overleftarrow{\mathbf{GS}} = \overleftarrow{\mathbf{SG}}^T$  and the indicated determinate of  $\mathbf{R}^{-1}$  is evaluated algebraically as

$$\det \mathbf{R}^{-1} = (A_1 - \overline{s_1 s_1} \cdot \rho_1) \cdot (A_2 - \overline{s_2 s_2} \cdot \rho_2) - \rho_1 \cdot \rho_2 \cdot \overline{s_1 s_2}^2 \quad (5-170d)$$

For the WSGG clear gas components we denote  $\overleftarrow{\mathbf{SS}} \Big|_{K=0} \equiv \overleftarrow{\mathbf{SS}}_0$  and  $\overleftarrow{\mathbf{SG}} \Big|_{K=0} \equiv \overleftarrow{\mathbf{SG}}_0 = \mathbf{0}$ . Finally the WSGG arrays of directed exchange areas are computed simply from  $a$ -weighted sums of the gray gas total exchange areas as

$$\overleftarrow{\mathbf{SS}} = \overleftarrow{\mathbf{SS}}_0 \cdot \begin{bmatrix} 1 - a_1 & 0 \\ 0 & 1 - a_2 \end{bmatrix} + \overleftarrow{\mathbf{SS}} \cdot \begin{bmatrix} a_1 & 0 \\ 0 & a_2 \end{bmatrix}$$

$$\overleftarrow{\mathbf{SG}} = \overleftarrow{\mathbf{SG}} \cdot a_g \quad (5-171a,b,c)$$

$$\overleftarrow{\mathbf{GS}} = \overleftarrow{\mathbf{GS}} \cdot \begin{bmatrix} a_1 & 0 \\ 0 & a_2 \end{bmatrix} \neq \overleftarrow{\mathbf{SG}}^T$$

and finally

$$\overleftarrow{\mathbf{GG}} = a_g \cdot 4KV - \overleftarrow{\mathbf{GS}} \cdot \begin{bmatrix} 1 \\ 1 \end{bmatrix} \quad (5-171d)$$

The results of this development may be further expanded into algebraic form with the aid of Eq. (5-127) to yield the following

$$\overleftarrow{S_2 S_1} = \frac{\varepsilon_1 \varepsilon_2 A_1 A_2 \overline{s_2 s_1} (1 - a_1)}{\varepsilon_1 \varepsilon_1 A_1 A_2 + (\varepsilon_1 A_1 \rho_2 + \varepsilon_2 A_2 \rho_1) \overline{s_2 s_1} + \rho_1 \rho_2 \overline{s_1 s_2}^2} + \frac{\varepsilon_1 \varepsilon_2 A_1 A_2 \overline{s_2 s_1} a_1}{\det \mathbf{R}^{-1}} \quad (5-171e)$$

$$\overleftarrow{\mathbf{SG}} = \begin{bmatrix} \varepsilon_1 A_1 [(A_2 - \rho_2 \cdot \overline{s_2 s_2}) \cdot \overline{s_1 g} + \rho_2 \cdot \overline{s_1 s_2} \cdot \overline{s_2 g}] a_g \\ \varepsilon_2 A_2 [(A_1 - \rho_1 \cdot \overline{s_1 s_1}) \cdot \overline{s_2 g} + \rho_1 \cdot \overline{s_1 s_2} \cdot \overline{s_1 g}] a_g \end{bmatrix} / \det \mathbf{R}^{-1} \quad (5-171f)$$

and

$$\overleftarrow{\mathbf{GS}} = \begin{bmatrix} \overleftarrow{G S_1} & \overleftarrow{G S_2} \end{bmatrix} \quad (5-171g)$$

whose matrix elements are given by  $\overleftarrow{GS}_1 \equiv \epsilon_1 A_1 [(A_2 - \rho_2 \overleftarrow{s}_1 \overleftarrow{s}_1) \cdot \overleftarrow{s}_1 \overleftarrow{g} + \rho_2 \overleftarrow{s}_1 \overleftarrow{s}_2 \cdot \overleftarrow{s}_2 \overleftarrow{g}] / \det \mathbf{R}^{-1}$  and  $\overleftarrow{GS}_2 \equiv \epsilon_2 A_2 [(A_1 - \rho_1 \overleftarrow{s}_1 \overleftarrow{s}_1) \cdot \overleftarrow{s}_2 \overleftarrow{g} + \rho_1 \overleftarrow{s}_1 \overleftarrow{s}_2 \cdot \overleftarrow{s}_1 \overleftarrow{g}] / \det \mathbf{R}^{-1}$ . Derivation of the scalar (algebraic) forms for the directed exchange areas here is done primarily for pedagogical purposes. Computationally, the only advantage is to obviate the need for a digital computer to evaluate a  $[2 \times 2]$  matrix inverse.

**Allowance for an Adiabatic Refractory with  $N = 1$  and  $M = 2$**   
 Put  $N = 1$  and  $M = 2$ , and let zone 2 represent the refractory surface. Let  $Q_2 = 0$  and  $\epsilon_2 \neq 0$ , and it then follows that we may define a refractory-aided directed exchange area  $\overleftarrow{S}_1 \overleftarrow{G}_R$  by

$$\overleftarrow{S}_1 \overleftarrow{G}_R = \overleftarrow{S}_1 \overleftarrow{G} + \frac{\overleftarrow{S}_1 \overleftarrow{S}_2 \cdot \overleftarrow{S}_2 \overleftarrow{G}}{\overleftarrow{S}_1 \overleftarrow{S}_2 + \overleftarrow{S}_2 \overleftarrow{G}} \quad (5-172a)$$

Assuming radiative equilibrium, the emissive power of the refractory may also be calculated from the companion equation

$$E_2 = \frac{\overleftarrow{S}_2 \overleftarrow{S}_1 \cdot E_1 + \overleftarrow{S}_2 \overleftarrow{G} \cdot E_g}{\overleftarrow{S}_2 \overleftarrow{S}_1 + \overleftarrow{S}_2 \overleftarrow{G}} \quad (5-172b)$$

In this circumstance, *all* the radiant energy originating in the gas volume is transferred to the *sole* sink zone  $A_1$ . Equation (5-172a) is thus tantamount to the statement that  $Q_1 = S'$  or that the net emission from the source ultimately must arrive at the sink. Notice that if  $\epsilon_1 = 0$ , Eq. (5-172a) leads to a physically incongruous statement since *all* the directed exchange areas would vanish and *no sink* would exist. Even for the simple case of  $M = 2, N = 1$ , the algebraic complexity of Eqs. (5-171) suggests that *numerical matrix manipulation* of directed exchange areas is to be preferred rather than calculations using algebraic formulas.

**Engineering Approximations for Directed Exchange Areas**  
 Use of the preceding equations for directed exchange areas with  $M = 2, N = 1$  and the WSGG clear plus gray gas spectral approximation requires knowledge of three independent direct exchange areas. It also formally requires evaluation of three WSGG weighting constants  $a_1, a_2,$  and  $a_g$  with respect to the three temperatures  $T_1, T_2,$  and  $T_g$ . Further simplifications may be made by assuming that radiant transfer for the *entire* enclosure is characterized by the *single* mean beam length  $L_M = 0.88 \cdot 4 \cdot V/A$ . The requisite direct exchange areas are then approximated by

$$\overleftarrow{SS} = \tau_g \begin{bmatrix} A_1 \cdot F_{1,1} & A_1 \cdot F_{1,2} \\ A_2 \cdot F_{2,1} & A_2 \cdot F_{2,2} \end{bmatrix} \quad (5-173a)$$

with 
$$\overleftarrow{sg} = (1 - \tau_g) \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} \quad (5-173b)$$

and for the particular case of a speckled enclosure

$$\overleftarrow{SS} = \frac{\tau_g}{A_1 + A_2} \begin{bmatrix} A_1^2 & A_1 \cdot A_2 \\ A_1 \cdot A_2 & A_2^2 \end{bmatrix} \quad (5-174a)$$

also with 
$$\overleftarrow{sg} = (1 - \tau_g) \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} \quad (5-174b)$$

where again  $\tau_g$  is obtained from the WSGG fit of gas emissivity. These approximate formulas clearly obviate the need for *exact* values of the direct exchange areas and may be used in conjunction with Eqs. (5-171).

For engineering calculations, an additional simplification is sometimes warranted. Again characterize the system by a single mean beam length  $L_M = 0.88 \cdot 4 \cdot V/A$  and employ the *identical* value of  $\tau_g = KL_M$  for all surface-gas transfers. The three  $a$  constants *might* then be obtained by a WSGG data-fitting procedure for gas emissivity and gas absorptivity which utilizes the three different temperatures  $T_g, T_1,$  and  $T_2$ . For engineering purposes we choose a simpler method, however. First calculate values of  $\epsilon_g$  and  $\alpha_{g,1}$  for gas temperature  $T_g$  with respect to the *dominant* (sink) temperature  $T_1$ . The *net* radiative flux between an isothermal gas mass at temperature  $T_g$  and a black isothermal bounding surface  $A_1$  at temperature  $T_1$  (the sink) is given by Eq. (5-138) as

$$Q_{1,g} = A_1 \sigma (\alpha_{g,1} T_1^4 - \epsilon_g T_g^4) \quad (5-175)$$

It is clear that transfer from the gas to the surface and transfer from the surface into the gas are characterized by two different constants of proportionality,  $\epsilon_g$  and  $\alpha_{g,1}$ . To allow for the difference between gas emissivity and absorptivity, it proves convenient to introduce a single *mean gas emissivity* defined by

$$\sigma [\epsilon_g T_g^4 - \alpha_{g,1} T_1^4] = \epsilon_m \sigma (T_g^4 - T_1^4) \quad (5-176a)$$

or 
$$\epsilon_m \equiv \frac{\epsilon_g - \alpha_{g,1} (T_1/T_g)^4}{1 - (T_1/T_g)^4} \quad (5-176b)$$

The calculation then proceeds by computing *two* values of  $\epsilon_m$  at the given  $T_g$  and  $T_1$  temperature pair and the two values of  $pL_M$  and  $2pL_M$ . We thereby obtain the expression  $\epsilon_m = a_m (1 - \tau_m)$ . It is then assumed that  $a_1 = a_2 = a_g = a_m$  for use in Eqs. (5-171). This simplification may be used for  $M > 2$  as long as  $N = 1$ . This simplification is illustrated in Example 12.

**Example 12: WSGG Clear plus Gray Gas Emissivity Calculations**  
 Methane is burned to completion with 20 percent excess air (50 percent relative humidity at 298 K or 0.0088 mol water/mol dry air) in a furnace chamber of floor dimensions  $3 \times 10$  m and height 5 m. The entire surface area of the enclosure is a gray sink with emissivity of 0.8 at temperature 1000 K. The confined gas is well stirred at a temperature of 1500 K. Evaluate the clear plus gray WSGG constants and the mean effective gas emissivity, and calculate the average radiative flux density to the enclosure surface.

*Two-zone model,  $M = 1, N = 1$ :* A single volume zone completely surrounded by a single sink surface zone.

*Function definitions:*

Gas emissivity:  $\epsilon_g F(T_g, pL, b, n) := b \cdot (pL - 0.015)^n + T_g$   
 Eq. (5-140a)

Gas absorptivity:  $\alpha_g 1F(T_g, T_1, pL, b, n)$   
 Eq. (5-141)  

$$:= \frac{\epsilon_g F(T_1, pL \cdot T_1 + T_g, b, n) \cdot T_1 \cdot (T_g + T_1)^{0.5}}{T_1}$$

Mean effective gas emissivity:  $\epsilon_{gm}(\epsilon_g, \alpha_g, T_g, T_1) := \frac{\epsilon_g - \alpha_g (T_1 + T_g)^4}{1 - (T_1 + T_g)^4}$   
 Eq. (5-176a)

*Physical constants:*  $\sigma \equiv 5.670400 \times 10^{-8} \frac{W}{m^2 \cdot K^4}$

*Enclosure input parameters:*

$T_g := 1500 \text{ K} \quad T_1 := 1000 \text{ K} \quad A_1 := 190 \text{ m}^2 \quad V := 150 \text{ m}^3$   
 $\epsilon_1 := 0.8 \quad \rho_1 := 1 - \epsilon_1 \quad \rho_1 = 0.2$   
 $E_1 := \sigma T_1^4 \quad E_g := \sigma T_g^4 \quad E_1 = 56.70 \frac{kW}{m^2} \quad E_g = 287.06 \frac{kW}{m^2}$

Stoichiometry yields the following mole table:

Mole Table: Basis 1.0 mol Methane

| Species          | MW     | Moles in | Mass in | Moles out | Y out   |
|------------------|--------|----------|---------|-----------|---------|
| CH <sub>4</sub>  | 16.04  | 1.00000  | 16.04   | 0.00000   | 0.00000 |
| O <sub>2</sub>   | 32.00  | 2.40000  | 76.80   | 0.40000   | 0.03193 |
| N <sub>2</sub>   | 28.01  | 9.02857  | 252.93  | 9.02857   | 0.72061 |
| CO <sub>2</sub>  | 44.01  | 0.00000  | 0.00    | 1.00000   | 0.07981 |
| H <sub>2</sub> O | 18.02  | 0.10057  | 1.81    | 2.10057   | 0.16765 |
| Totals           | 27.742 | 12.52914 | 347.58  | 1.52914   | 1.00000 |

$p_W := .16765 \text{ atm} \quad p_C := 0.07981 \text{ atm} \quad p := p_W + p_C \quad p = 0.2475 \text{ atm}$   
 $p_W + p_C = 2.101$

The mean beam length is approximated by

$$L_M := 0.88 \cdot 4 \cdot V \div A_1 \quad L_M = 2.7789 \text{ m}$$
  
 and 
$$pL_M := p \cdot L_M \quad pL_M = 0.6877 \text{ atm} \cdot \text{m} \quad 2pL_M := 1.3754$$

The gas emissivities and absorptivities are then calculated from the two constant correlation in Table 5-5 (column 5 with  $p_w/p_c = 2.0$ ) as follows:

$\epsilon_{g1} := \epsilon_g F(1500, pL_M, 540, .42) \quad \epsilon_{g1} = 0.3048$

$$\begin{aligned}\epsilon_{g2} &:= \epsilon_g F(1500, 2pL_M, 540, .42) & \epsilon_{g2} &= 0.4097 \\ \alpha_{g11} &:= \alpha_g 1F(1500, 1000, pL_M, 444, .34) & \alpha_{g11} &= 0.4124 \\ \alpha_{g12} &:= \alpha_g 1F(1500, 1000, 2pL_M, 444, .34) & \alpha_{g12} &= 0.5250\end{aligned}$$

Case (a): Compute Flux Density Using Exact Values of the WSGG Constants

$$\begin{aligned}\tau_g &:= \frac{\epsilon_{g2}}{\epsilon_{g1}} - 1 & a_g &:= \frac{\epsilon_{g1}}{1 - \tau_g} & \epsilon_g &:= a_g \cdot (1 - \tau_g) & a_{g1} &:= \frac{\alpha_{g11}}{1 - \tau_g} \\ \tau_g &= 0.3442 & a_g &= 0.4647 & \epsilon_g &= 0.3048 & a_{g1} &= 0.6289\end{aligned}$$

and the WSGG gas absorption coefficient (which is necessary for calculation of direct exchange areas) is calculated as  $K_1 := \frac{-\ln \tau_g}{L_M}$  or  $K_1 = 0.3838 \frac{1}{m}$

Compute directed exchange areas:  
Eqs. (5-169)

$$\begin{aligned}s1g &:= (1 - \tau_g) \cdot A_1 & s1g &= 124.61 \text{ m}^2 \\ DS1G &:= \frac{a_g \cdot \epsilon_1 \cdot A_1 \cdot s1g}{\epsilon_1 \cdot A_1 + \rho_1 \cdot s1g} & DGS1 &:= \frac{a_{g1} \cdot \epsilon_1 \cdot A_1 \cdot s1g}{\epsilon_1 \cdot A_1 + \rho_1 \cdot s1g} \\ DS1G &= 49.75 \text{ m}^2 & DGS1 &= 67.32 \text{ m}^2\end{aligned}$$

And finally the gas to sink flux density is computed as

$$Q_1 := DGS1 \cdot E_1 - DS1G \cdot E_g \quad Q_1 = -10464.0 \text{ kW} \quad \frac{Q_1}{A_1} = -55.07 \frac{\text{kW}}{\text{m}^2}$$

Case (b): Compute the Flux Density Using Mean Effective Gas Emissivity Approximation

$$\begin{aligned}\epsilon_{gm1} &:= \epsilon_{gm}(\epsilon_{g1}, \alpha_{g11}, T_g, T_1) & \epsilon_{gm1} &= 0.2783 \\ \epsilon_{gm2} &:= \epsilon_{gm}(\epsilon_{g2}, \alpha_{g12}, T_g, T_1) & \epsilon_{gm2} &= 0.3813 \\ \tau_m &:= \frac{\epsilon_{gm2}}{\epsilon_{gm1}} - 1 & a_m &:= \frac{\epsilon_{gm1}}{1 - \tau_m} & \epsilon_{gm} &:= a_m \cdot (1 - \tau_m) \\ \tau_m &= 0.3701 & a_m &= 0.4418 & \epsilon_{gm} &= 0.2783 & s1g_m &:= (1 - \tau_m) \cdot A_1 \\ S1G_m &:= \frac{\epsilon_1 \cdot a_m \cdot s1g_m \cdot A_1}{\epsilon_1 \cdot A_1 + \rho_1 \cdot s1g_m} & S1G_m &= 45.68 \text{ m}^2 & s1g_m &= 119.67 \text{ m}^2 \\ q_{1m} &:= \frac{S1G_m \cdot (E_1 - E_g)}{A_1} & q_{1m} &= -55.38 \frac{\text{kW}}{\text{m}^2} \\ \text{compared with } \frac{Q_1}{A_1} &= -55.07 \frac{\text{kW}}{\text{m}^2}\end{aligned}$$

The computed flux densities are nearly equal because there is a *single* sink zone  $A_1$ . (This example was developed as a MATHCAD 14<sup>®</sup> worksheet. Mathcad is a registered trademark of Parametric Technology Corporation.)

## ENGINEERING MODELS FOR FUEL-FIRED FURNACES

Modern digital computation has evolved methodologies for the design and simulation of fuel-fired combustion chambers and furnaces which incorporate virtually *all* the transport phenomena, chemical kinetics, and thermodynamics studied by chemical engineers. Nonetheless, there still exist many furnace design circumstances where such computational sophistication is not always appropriate. Indeed, a practical need still exists for simple engineering models for purposes of conceptual process design, cost estimation, and the correlation of test performance data. In this section, the zone method is used to develop perhaps the simplest **computational template** available to address some of these practical engineering needs.

**Input/Output Performance Parameters for Furnace Operation** The term **firing density** is typically used to define the basic *operational input parameter* for fuel-fired furnaces. In practice, firing density is often defined as the input fuel feed rate per unit area (or volume) of furnace heat-transfer surface. Thus defined, the firing density is a *dimensional quantity*. Since the feed enthalpy rate  $H_f$  is

proportional to the feed rate, we employ the sink area  $A_1$  to define a **dimensionless firing density** as  $\bar{N}_{FD} = H_f / \sigma T_{Ref}^4 A_1$  where  $T_{Ref}$  is some characteristic reference temperature. In practice, gross furnace *output performance* is often described by using one of several *furnace efficiencies*. The most common is the **gas or gas-side furnace efficiency**  $\eta_g$ , defined as the total enthalpy transferred to furnace internals divided by the total available feed enthalpy. Here the total available feed enthalpy is defined to include the lower heating value (LHV) of the fuel plus any air preheat above an arbitrary ambient datum temperature. Under certain conditions the definition of furnace efficiency reduces to some variant of the simple equation  $\eta_g = (T_{Ref} - T_{out}) / (T_{Ref} - T_0)$  where again  $T_{Ref}$  is some reference temperature appropriate to the system in question.

**The Long Plug Flow Furnace (LPFF) Model** If a combustion chamber of cross-sectional area  $A_{Duct}$  and perimeter  $P_{Duct}$  is sufficiently long in the direction of flow, compared to its mean hydraulic radius,  $L \gg R_h = A_{Duct} / P_{Duct}$ , the radiative flux from the gas to the bounding surfaces can sometimes be adequately characterized by the *local* gas temperature. The physical rationale for this is that the *magnitudes* of the opposed upstream and downstream radiative fluxes through a cross section transverse to the direction of flow are sufficiently large as to substantially balance each other. Such a situation is not unusual in engineering practice and is referred to as the *long furnace approximation*. As a result, the radiative flux from the gas to the bounding surface may then be approximated using *two-dimensional* directed exchange areas,  $\overleftarrow{S_1G} / A_1 \equiv \frac{\partial(S_1G)}{\partial A_1}$ , calculated using methods as described previously.

Consider a duct of length  $L$  and perimeter  $P$ , and assume plug flow in the direction of flow  $z$ . Further assume high-intensity mixing at the entrance end of the chamber such that combustion is *complete* as the combustion products enter the duct. The duct then acts as a long heat exchanger in which heat is transferred to the walls at constant temperature  $T_1$  by the combined effects of radiation and convection. Subject to the long furnace approximation, a differential energy balance on the duct then yields

$$\dot{m} \bar{C}_p \frac{dT_g}{dz} = P \left[ \frac{\overleftarrow{S_1G}}{A_1} \sigma (T_g^4 - T_1^4) + h(T_g - T_1) \right] \quad (5-177)$$

where  $\dot{m}$  is the mass flow rate and  $\bar{C}_p$  is the heat capacity per unit mass. Equation (5-177) is nonlinear with respect to temperature. To solve Eq. (5-177), first linearize the convective heat-transfer term in the right-hand side with the approximation  $\Delta T = T_2 - T_1 \approx (T_2^3 - T_1^3) / 4\bar{T}_{1,2}^2$  where  $\bar{T}_{1,2} = (T_1 + T_2) / 2$ . This linearization underestimates  $\Delta T$  by no more than 5 percent when  $T_2 / T_1 < 1.59$ . Integration of Eq. (5-177) then leads to the solution

$$\ln \left[ \frac{(T_{g,out} - T_1)(T_{g,in} + T_1)}{(T_{g,out} + T_1)(T_{g,in} - T_1)} \right] + 2.0 \tan^{-1} \left[ \frac{(T_{g,in} - T_{g,out}) \cdot T_1}{(T_1^2 + T_{g,in} \cdot T_{g,out})} \right] = -\frac{4}{D_{eff}} \quad (5-178)$$

The LPFF model is described by only two dimensionless parameters, namely an *effective* firing density and a dimensionless sink temperature, viz.,

$$D_{eff} = \frac{N_{FD}}{\left( \frac{\overleftarrow{S_1G}}{A_1} \right) + N_{CR}} \quad \text{and} \quad \Theta_1 = T_1 / T_{g,in} \quad (5-178a,b)$$

Here the dimensionless firing density,  $N_{FD}$ , and a dimensionless convection-radiation number  $N_{CR}$  are defined as

$$N_{FD} = \frac{\dot{m} \bar{C}_p}{\sigma T_1^3 A_1} \quad \text{and} \quad N_{CR} = \frac{h}{4\sigma \bar{T}_{g,1}^3} \quad (5-178c,d)$$

where  $A_1 = PL$  is the duct surface area (the sink area), and  $\bar{T}_{g,1} = (T_g + T_1) / 2$  is treated as a constant. This definition of the effective dimensionless firing density,  $D_{eff}$ , clearly delineates the relative

roles of radiation and convective heat transfer since radiation and convection are identified as *parallel (electrical) conductances*.

In analogy with a conventional heat exchanger, Eq. (5-178) displays two asymptotic limits. First define

$$\eta_f = \frac{T_{g,\text{in}} - T_{g,\text{out}}}{T_{g,\text{in}} - T_1} = 1 - \frac{T_{g,\text{out}} - T_1}{T_{g,\text{in}} - T_1} \quad (5-179)$$

as the efficiency of the long furnace. The two asymptotic limits with respect to firing density are then given by

$$D_{\text{eff}} \ll 1, \quad T_{g,\text{out}} \rightarrow T_1 \quad \eta_f \rightarrow 1 \quad (5-179a)$$

and

$$D_{\text{eff}} \gg 1, \quad T_{g,\text{out}} \rightarrow T_{g,\text{in}}$$

$$\eta_f \rightarrow \frac{4}{D_{\text{eff}} \left[ 1 - \frac{R-1}{R+1} - 2 \frac{R-1}{R^2+1} \right]} \quad (5-179b)$$

where  $R \equiv T_{g,\text{in}}/T_1 = 1/\Theta_1$ .

For low firing rates, the exit temperature of the furnace gases approaches that of the sink, i.e., sufficient residence time is provided for nearly complete heat removal from the gases. When the combustion chamber is overfired, only a small fraction of the available feed enthalpy heat is removed within the furnace. The exit gas temperature then remains essentially that of the inlet temperature, and the furnace efficiency tends asymptotically to zero.

It is important to recognize that the two-dimensional exchange area  $\frac{\overline{S_1 G}}{A_1} \equiv \frac{\partial(\overline{S_1 G})}{\partial A_1}$  in the definition of  $D_{\text{eff}}$  can represent a *lumped* two-

dimensional exchange area of somewhat arbitrary complexity. This quantity also contains *all* the information concerning furnace geometry and gas and surface emissivities. To compare the relative importance of radiation with respect to convection, suppose  $h = 10 \text{ Btu}/(\text{hr-ft}^2 \cdot ^\circ\text{R}) = 0.057 \text{ kW}/(\text{K} \cdot \text{m}^2)$  and  $T_{g,1} = 1250 \text{ K}$ , which leads to the numerical value  $N_{\text{CR}} = 0.128$ ; or, in general,  $N_{\text{CR}}$  is of order 0.1 or less. The importance of the radiation contribution is estimated by bounding the magnitude of the dimensionless directed exchange area. For the case of a single gas zone completely surrounded by a black enclosure, Eq. (5-169) reduces to simply  $\overline{S_1 G}/A_1 = \epsilon_g \leq 1.0$ , and it is evident that the magnitude of the radiation contribution never exceeds unity. At high temperatures, radiative effects can easily dominate other modes of heat transfer by an order of magnitude or more. When mean beam length calculations are employed, use  $L_M/D = 0.94$  for a cylindrical cross section of diameter  $D$ , and

$$L_{M0} = \frac{2H \cdot W}{H + W}$$

for a rectangular duct of height  $H$  and width  $W$ .

**The Well-Stirred Combustion Chamber (WSCC) Model**  
Many combustion chambers utilize high-momentum feed conditions with associated high-intensity mixing. The **well-stirred combustion chamber (WSCC) model** assumes a single gas zone and high-intensity mixing. Moreover, combustion and heat transfer are visualized to occur *simultaneously* within the combustion chamber. The WSCC model is characterized by some *six* temperatures which are listed in rank order as  $T_0$ ,  $T_{\text{air}}$ ,  $T_1$ ,  $T_e$ ,  $T_g$ , and  $T_f$ . Even though the combustion chamber is well mixed, it is *arbitrarily* assumed that the gas temperature within the enclosure  $T_g$  is *not necessarily equal* to the gas exit temperature  $T_e$ . Rather the two temperatures are related by the simple relation  $\Delta T_{ge} \equiv T_g - T_e$ , where  $\Delta T_{ge} \approx 170 \text{ K}$  (as a representative value) is introduced as an *adjustable parameter* for purposes of data fitting and to make allowance for nonideal mixing. In addition,  $T_0$  is the ambient temperature,  $T_{\text{air}}$  is the air preheat temperature, and  $T_f$  is a *pseudoadiabatic flame temperature*, as shall be explained in the following development. The condition  $\Delta T_{ge} \equiv 0$  is intended to simulate a perfect continuous well-stirred reactor (CSTR).

**Dimensional WSCC Approach** A macroscopic enthalpy balance on the well-stirred combustion chamber is written as

$$-\Delta H = H_{\text{in}} - H_{\text{out}} = Q_{\text{Rad}} + Q_{\text{Con}} + Q_{\text{Ref}} \quad (5-180)$$

Here  $Q_{\text{Rad}} = \overline{S_1 G_R} \sigma (T_g^4 - T_1^4)$  represents radiative heat transfer to the sink (with due allowance for the presence of any refractory surfaces). And the two terms  $Q_{\text{Con}} = h_1 A_1 (T_g - T_1)$  and  $Q_{\text{Ref}} = U A_R (T_g - T_0)$  formulate the convective heat transfer to the sink and *through* the refractory, respectively.

Formulation of the left-hand side of Eq. (5-180) requires representative thermodynamic data and information on the combustion stoichiometry. In particular, the former includes the lower heating value of the fuel, the temperature-dependent molal heat capacity of the inlet and outlet streams, and the air preheat temperature  $T_{\text{air}}$ . It proves especially convenient now to introduce the definition of a pseudoadiabatic flame temperature  $T_f$ , which is *not* the true adiabatic flame temperature, but rather is an adiabatic flame temperature based on the average heat capacity of the combustion products over the temperature interval  $T_0 < T < T_e$ . The calculation of  $T_f$  does not allow for dissociation of chemical species and is a surrogate for the total enthalpy content of the input fuel-air mixture. It also proves to be an especially convenient system *reference temperature*. Details for the calculation of  $T_f$  are illustrated in Example 13.

In terms of this particular definition of the pseudoadiabatic flame temperature  $T_f$ , the total enthalpy change and gas efficiency are given simply as

$$\Delta H = \dot{H}_f - \dot{m} \cdot \overline{C}_{P,\text{Prod}} (T_e - T_0) = \dot{m} \overline{C}_{P,\text{Prod}} (T_f - T_e) \quad (5-181a,b)$$

where  $\dot{H}_f \equiv \dot{m} \cdot \overline{C}_{P,\text{Prod}} (T_f - T_0)$  and  $T_e = T_g - \Delta T_{ge}$ . This particular definition of  $T_f$  leads to an especially convenient formulation of furnace efficiency

$$\eta_g = Q/\dot{H}_f = \frac{\dot{m} \cdot \overline{C}_{P,\text{Prod}} (T_f - T_e)}{\dot{m} \cdot \overline{C}_{P,\text{Prod}} (T_f - T_0)} = \frac{T_f - T_e}{T_f - T_0} \quad (5-182)$$

In Eq. (5-182),  $\dot{m}$  is the total mass flow rate and  $\overline{C}_{P,\text{Prod}}$  [J/(kg·K)] is defined as the average heat capacity of the product stream over the temperature interval  $T_0 < T < T_e$ .

The final overall enthalpy balance is then written as

$$\dot{m} \cdot \overline{C}_{P,\text{Prod}} (T_f - T_e) = \overline{S_1 G_R} \sigma (T_g^4 - T_1^4) + h_1 A_1 (T_g - T_1) + U A_R (T_g - T_0) \quad (5-183)$$

with  $T_e = T_g - \Delta T_{ge}$ .

Equation (5-183) is a nonlinear algebraic equation which may be solved by a variety of iterative methods. The *sole* unknown quantity, however, in Eq. (5-183) is the gas temperature  $T_g$ . It should be recognized, in particular, that  $T_f$ ,  $T_e$ ,  $\overline{C}_{P,\text{Prod}}$ , and the directed exchange area are all explicit functions of  $T_g$ . The method of solution of Eq. (5-183) is demonstrated in some detail in Example 13.

**Dimensionless WSCC Approach** In Eq. (5-183), assume the convective heat loss through the refractory is negligible, and linearize the convective heat transfer to the sink. These approximations lead to the result

$$\dot{m} \cdot \overline{C}_{P,\text{Prod}} (T_f - T_g + \Delta T_{ge}) = \overline{S_1 G_R} \sigma (T_g^4 - T_1^4) + h_1 A_1 (T_g - T_1) / 4 \overline{T}_{g,1}^3 \quad (5-184)$$

where  $\overline{T}_{g,1} = (T_g + T_1)/2$  is some characteristic average temperature which is taken as constant. Now normalize all temperatures based on the pseudoadiabatic temperature as in  $\Theta_i = T_i/T_f$ . Equation (5-184) then leads to the dimensionless equation

$$D_{\text{eff}} (1 - \Theta_g + \Delta^\circ) = (\Theta_g^4 - \Theta_1^4) \quad (5-185)$$

where again  $D_{\text{eff}} = N_{\text{FD}} / (\overline{S_1 G}/A_1 + N_{\text{CR}})$  is defined *exactly* as in the case of the LPFF model, with the proviso that the WSCC dimensionless firing density is defined here as  $N_{\text{FD}} = \dot{m} \overline{C}_{P,\text{Prod}} / (\sigma T_f^3 A_1)$ . The dimensionless furnace efficiency follows directly from Eq. (5-182) as

$$\eta_g = \frac{1 - \Theta_e}{1 - \Theta_0} = \frac{1 - \Theta_g + \Delta^\circ}{1 - \Theta_0} \quad (5-186a)$$

We also define a **reduced furnace efficiency**  $\eta'_g$

$$\eta'_g \equiv (1 - \Theta_0)\eta_g = 1 - \Theta_g + \Delta^\circ \tag{5-186b}$$

Since Eq. (5-186b) may be rewritten as  $\Theta_g = (1 + \Delta^\circ - \eta'_g)$ , combination of Eqs. (5-185) and (5-186b) then yields the final result

$$D_{\text{eff}}\eta'_g = (1 + \Delta^\circ - \eta'_g)^4 - \Theta_1^4 \tag{5-187}$$

Equation (5-187) provides an *explicit* relation between the modified furnace efficiency and the effective firing density directly in which the gas temperature is eliminated.

Equation (5-187) has two asymptotic limits

$$\begin{aligned} D_{\text{eff}} \ll 1 \quad \Theta_g &\rightarrow \Theta_1 \\ \eta'_g &\rightarrow 1 - \Theta_1 + \Delta^\circ \end{aligned} \tag{5-188a}$$

and

$$\begin{aligned} D_{\text{eff}} \gg 1 \quad \Theta_g &\rightarrow 1 + \Delta^\circ \quad \text{and} \quad \Theta_e \rightarrow 1 \\ \eta'_g &\rightarrow \frac{(1 + \Delta^\circ)^4 - \Theta_1^4}{D_{\text{eff}} + 4(1 + \Delta^\circ)^3} \end{aligned} \tag{5-188b}$$

Figure 5-23 is a plot of  $\eta'_g$  versus  $D_{\text{eff}}$  computed from Eq. (5-187) for the case  $\Delta^\circ = 0$ .

The asymptotic behavior of Eq. (5-189) mirrors that of the LPPF model. Here, however, for low firing densities, the exit temperature of the furnace exit gases approaches  $\Theta_e = \Theta_1 - \Delta^\circ$  rather than the sink temperature. Moreover, for  $D_{\text{eff}} \ll 1$  the reduced furnace efficiency adopts the constant value  $\eta'_g = 1 - \Theta_e = 1 + \Delta^\circ - \Theta_1$ . Again at very high firing rates, only a very small fraction of the available feed enthalpy heat is recovered within the furnace. Thus the exit gas temperature remains nearly unchanged from the pseudoadiabatic flame temperature  $[T_e \approx T_f]$  and the gas-side efficiency necessarily approaches zero.

**Example 13: WSCC Furnace Model Calculations** Consider the furnace geometry and combustion stoichiometry described in Example 12. The end-fired furnace is 3 m wide, 5 m tall, and 10 m long. Methane at a firing rate of 2500 kg/h is burned to completion with 20 percent excess air which is preheated to 600°C. The speckled furnace model is to be used. The sink (zone 1)

occupies 60 percent of the total interior furnace area and is covered with two rows of 5-in (0.127-m) tubes mounted on equilateral centers with a center-to-center distance of twice the tube diameter. The sink temperature is 1000 K, and the tube emissivity is 0.7. Combustion products discharge from a 10-m<sup>2</sup> duct in the roof which is also tube-screen covered and is to be considered part of the sink. The refractory (zone 2) with emissivity 0.6 is radiatively adiabatic but demonstrates a small convective heat loss to be calculated with an overall heat transfer coefficient  $U$ . Compute all unknown furnace temperatures, the gas-side furnace efficiency, and the mean heat flux density through the tube surface. Use the *dimensional* solution approach for the well-stirred combustor model and compare computed results with the *dimensionless* WSCC and LPPF models. Computed values for mean equivalent gas emissivity obtained from Eq. (5-174b) and Table 5-5 for  $T_g = 2000$  K for  $L_M = 2.7789$  m and  $T_1 = 1000$  K are found to be

|                |                 |                    |                        |
|----------------|-----------------|--------------------|------------------------|
| $T_g = 1500$ K | $a_m = 0.44181$ | $\tau_m = 0.37014$ | $\epsilon_m = 0.27828$ |
| $T_g = 2000$ K | $a_m = 0.38435$ | $\tau_m = 0.41844$ | $\epsilon_m = 0.22352$ |

Over this temperature range the gas emissivity may be calculated by linear interpolation. Additional heat-transfer and thermodynamic data are supplied in context.

*Three-zone speckled furnace model, M = 2, N = 1:*

Zone 1: Sink (60 percent of total furnace area)

Zone 2: Refractory surface (40 percent of total furnace area)

*Physical constants:*

$$\sigma = 5.670400 \times 10^{-8} \frac{\text{W}}{\text{m}^2 \cdot \text{K}^4}$$

*Linear interpolation function for mean effective gas emissivity constants:*

$$\text{LINTF}(T, Y_2, Y_1) := \frac{Y_1 \cdot (2000 \text{ K} - T) + Y_2 \cdot (T - 1500 \text{ K})}{500 \text{ K}} \quad (1500 \text{ K} < T < 2000 \text{ K})$$

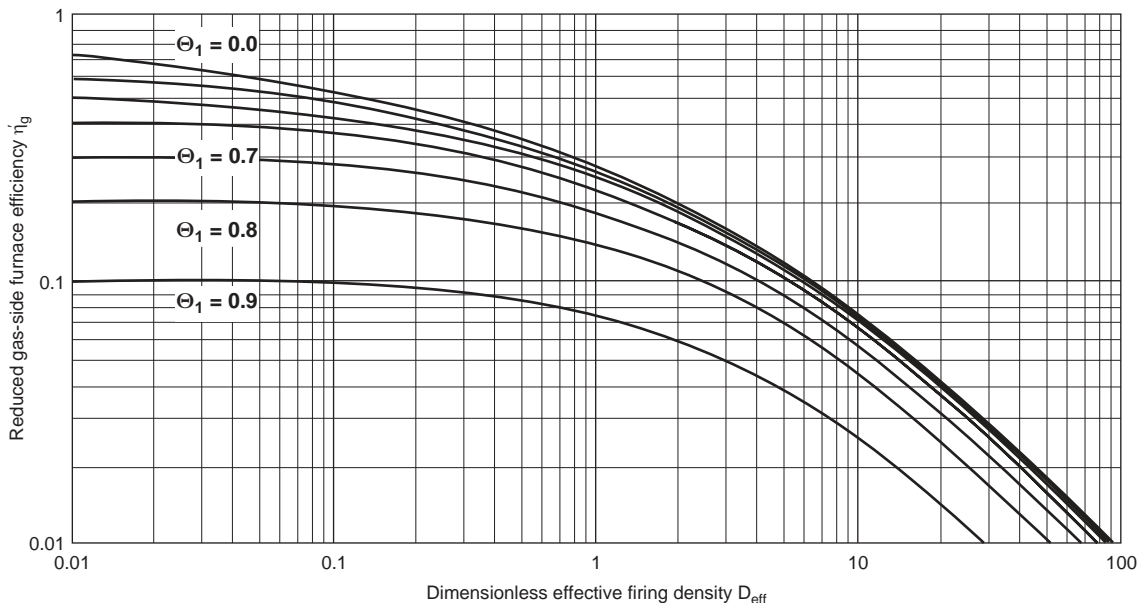

*Enclosure input parameters:*

$$V_{\text{tot}} := 150 \text{ m}^3 \quad A_{\text{tot}} := 190 \text{ m}^2 \quad C_1 := 0.6 \quad C_2 := 1 - C_1$$

$$A_1 := C_1 \cdot A_{\text{tot}} \quad A_2 := C_2 \cdot A_{\text{tot}} \quad D_{\text{tube}} := .127 \text{ m}$$

*Direct exchange areas for WSCC clear gas component (temperature independent):*

$$F := \begin{pmatrix} C_1 & C_2 \\ C_1 & C_2 \end{pmatrix} \quad \text{AI} := \begin{pmatrix} A_1 & 0 \\ 0 & A_2 \end{pmatrix} \quad \text{ss1} := \text{AI} \cdot F \quad \text{ss1} = \begin{pmatrix} 68.40 & 45.60 \\ 45.60 & 30.40 \end{pmatrix} \text{m}^2$$

**FIG. 5-23** Reduced gas-side furnace efficiency versus effective firing density for well-stirred combustion chamber model.  $\Delta^\circ = 0$ ,  $\Theta_1 = 0.0, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9$ .

## 5-42 HEAT AND MASS TRANSFER

Equivalent gray plane emissivity calculations for sink:

$$\epsilon_{\text{tube}} := 0.7 \quad F_{\text{bar}} := 0.987 \quad (\text{from Fig. 5-13, curve 6 with ratio} = 2.0)$$

$$\epsilon_{1,\text{eq}} := \frac{1}{\left(\frac{1}{\epsilon_1} - 1\right) + 2 \cdot \frac{D_{\text{tube}}}{2 \cdot \pi \cdot D_{\text{tube}}} \cdot \left(\frac{1}{\epsilon_{\text{tube}}} - 1\right) + \frac{1}{F_{\text{bar}}}} \quad \epsilon_{1,\text{eq}} = 0.86988$$

$$\epsilon_1 := \epsilon_{1,\text{eq}} \quad \epsilon_2 := 0.6 \quad \epsilon I := \begin{pmatrix} \epsilon_1 & 0 \\ 0 & \epsilon_2 \end{pmatrix} \quad \rho I := \text{identity}(2) - \epsilon I$$

Total exchange areas for WSGG clear gas component:

$$R1 := (AI - ss1 \cdot \rho I)^{-1} \quad SS1 := \epsilon I \cdot AI \cdot R1 \cdot ss1 \cdot \epsilon I \quad SS1 = \begin{pmatrix} 67.93 & 31.24 \\ 31.24 & 14.36 \end{pmatrix} \text{m}^2$$

Temperature and emissive power input data:

$$T_1 := 1000.0 \text{ K} \quad T_{\text{air}} := 873.15 \text{ K}$$

$$T_0 := 298.15 \text{ K} \quad \Delta T_{\text{gr}} := 170 \text{ K} \quad E_1 := \sigma \cdot T_1^4 \quad E_1 = 56.704 \frac{\text{kW}}{\text{m}^2}$$

Mean beam length calculations:

$$L_{M0} := 4 \cdot \frac{V_{\text{tot}}}{A_{\text{tot}}} \quad L_{M0} = 3.1579 \text{ m} \quad L_M := 0.88 L_{M0} \quad L_M = 2.7789 \text{ m}$$

Stoichiometric and thermodynamic input data:

$$\text{MCH}_{4,\text{dot}} := 2500 \frac{\text{kg}}{\text{h}} \quad \text{MW}_{\text{CH}_4} := 16.04 \frac{\text{g}}{\text{mol}} \quad \text{MW}_{\text{in}} := 27.742 \frac{\text{g}}{\text{mol}}$$

$$\Sigma \text{Mols} := 12.52914 \quad \text{LHV} := 191760 \frac{\text{cal}}{\text{mol}} \quad \text{MCP}_{\text{air}} := 7.31 \frac{\text{cal}}{\text{mol} \cdot \text{K}}$$

$$\text{MCP}(T) := \left[ 7.01 + 0.875 \left( \frac{T}{1000 \text{ K}} \right) \right] \frac{\text{cal}}{\text{mol} \cdot \text{K}} \quad (800 \text{ K} < T < 1200 \text{ K})$$

$M_{\text{dot}}$  is the total mass flowrate and  $\text{NCH}_{4,\text{dot}}$  is the molal flowrate of  $\text{CH}_4$ .

$$M_{\text{dot}} := \frac{\text{MCH}_{4,\text{dot}} \cdot \text{MW}_{\text{in}} \cdot \Sigma \text{Mols}}{\text{MW}_{\text{CH}_4}} \quad \text{NCH}_{4,\text{dot}} := \frac{\text{MCH}_{4,\text{dot}}}{\text{MW}_{\text{CH}_4}}$$

$$M_{\text{dot}} = 54174.5 \frac{\text{kg}}{\text{h}} \quad \text{NCH}_{4,\text{dot}} = 155860.3 \frac{\text{mol}}{\text{h}}$$

Overall refractory heat-transfer coefficient:

$$D_r := 0.343 \text{ m} \quad k_r := 0.00050 \frac{\text{kW}}{\text{m} \cdot \text{K}}$$

$$h_0 := 0.0114 \frac{\text{kW}}{\text{m}^2 \cdot \text{K}} \quad h_0 = 2.0077 \frac{\text{Btu}}{\text{h} \cdot \text{ft}^2 \cdot \text{R}} \quad h_1 := 0.0170 \frac{\text{kW}}{\text{m}^2 \cdot \text{K}}$$

$$h_1 = 2.9939 \frac{\text{Btu}}{\text{h} \cdot \text{ft}^2 \cdot \text{R}} \quad U := \frac{1}{\frac{1}{h_0} + \frac{1}{h_1} + \frac{D_r}{k_r}}$$

$$U = 0.001201 \frac{\text{kW}}{\text{m}^2 \cdot \text{K}} \quad U = 0.2115 \frac{\text{Btu}}{\text{h} \cdot \text{ft}^2 \cdot \text{R}}$$

START OF ITERATION LOOP: Successive Substitution with  $T_g$  as the Trial Variable

$$\text{Assume } T_g := 1759.1633222447 \text{ K} \quad T_r := T_g - \Delta T_{\text{gr}} \quad T_e = 1589.2 \text{ K}$$

$$E_g := \sigma \cdot T_g^4 \quad E_g = 543.05 \frac{\text{kW}}{\text{m}^2}$$

Compute temperature-dependent mean effective gas emissivity via linear interpolation:

$$\tau_m := \text{LINTF}(T_g, 0.37014, 0.418442) \quad a_m := \text{LINTF}(T_g, 0.44181, 0.38435)$$

$$\tau_m = 0.3934 \quad a_m = 0.4141 \quad \epsilon_m := a_m \cdot (1 - \tau_m) \quad \epsilon_m = 0.2512$$

Compare interpolated value:

$$\epsilon_{\text{com}} := \text{LINTF}(T_g, 0.27828, 0.22352) \quad \epsilon_{\text{com}} = 0.2519$$

Direct and total exchange areas for WSGG gray gas component:

$$ss2 := \tau_m \cdot ss1 \quad sg2 := (AI - ss2) \begin{bmatrix} 1 \\ 1 \end{bmatrix} \quad R2 := (AI - ss2 \cdot \rho I)^{-1}$$

$$ss2 = \begin{pmatrix} 26.91 & 17.94 \\ 17.94 & 11.96 \end{pmatrix} \text{m}^2 \quad sg2 = \begin{pmatrix} 69.15 \\ 46.10 \end{pmatrix} \text{m}^2 \quad SS2 := \epsilon I \cdot AI \cdot R2 \cdot ss2 \cdot \epsilon I$$

Compute directed exchange areas:

$$DSS := (1 - a_m) \cdot SS1 + a_m \cdot SS2 \quad DSG := a_m \cdot \epsilon I \cdot AI \cdot R2 \cdot sg2$$

Refractory augmented directed gas-sink exchange area:

$$\text{DS1GR} := \text{DSG}_1 + \frac{\text{DSS}_{1,2} \cdot \text{DSG}_2}{\text{DSS}_{1,2} + \text{DSG}_2} \quad \text{DS1GR} = 35.59 \text{ m}^2 \quad \text{Eq. (5-172a)}$$

Compute refractory temperature ( $T_2$ ); assume radiative equilibrium:

$$\text{Equation (5-172b): } E_2 := \frac{\text{DSS}_{2,1} \cdot E_1 + \text{DSG}_{2,1} \cdot E_g}{\text{DSS}_{2,1} + \text{DSG}_{2,1}}$$

$$E_2 = 231.24 \frac{\text{kW}}{\text{m}^2}$$

$$T_2 := \left( \frac{E_2}{\sigma} \right)^{0.25} \quad T_2 = 1421.1 \text{ K}$$

Enthalpy balance: Basis: 1 mole  $\text{CH}_4$ :

$$h_{\text{in}} := \text{LHV} + (\Sigma \text{Mols} - 1) \cdot \text{MCP}_{\text{air}} \cdot (T_{\text{air}} - T_0) \quad h_{\text{in}} = 240219.9 \frac{\text{cal}}{\text{mol}}$$

Compute pseudoadiabatic flame temperature  $T_f$ :

$$T_f := T_0 + \frac{h_{\text{in}}}{\Sigma \text{Mols} \cdot \text{MCP}(T_e)} \quad h_{\text{out}} := \Sigma \text{Mols} \cdot \text{MCP}(T_e) \cdot (T_e - T_0)$$

$$T_f = 2580.5 \text{ K} \quad h_{\text{out}} = 135580.8 \frac{\text{cal}}{\text{mol}}$$

$$H_{\text{in}} := \text{NCH}_{4,\text{dot}} \cdot h_{\text{in}} \quad H_{\text{out}} := \text{NCH}_{4,\text{dot}} \cdot h_{\text{out}} \quad \Delta H := H_{\text{out}} - H_{\text{in}}$$

$$H_{\text{in}} = 43543.59 \text{ kW} \quad H_{\text{out}} = 24630.51 \text{ kW} \quad \Delta H = -18913.08 \text{ kW}$$

Overall enthalpy balance:

$$Q1_g := \text{DS1GR} \cdot (E_g - E_1) \quad Q1_g = 17308.45 \text{ kW}$$

$$Q1_{\text{Con}} := h_1 \cdot A_1 \cdot (T_g - T_1) \quad Q1_{\text{Con}} = 1471.26 \text{ kW}$$

$$Q2_{\text{Con}} := U \cdot A_2 \cdot (T_g - T_0) \quad Q2_{\text{Con}} = 133.37 \text{ kW}$$

$$\text{ERROR} := Q1_g + Q1_{\text{Con}} + Q2_{\text{Con}} + \Delta H \quad \% \text{ERROR1} := 100 \frac{\text{ERROR}}{\Delta H}$$

$$\text{ERROR} = -0.0000 \text{ kW} \quad \% \text{ERROR1} = 0.00000$$

$$T_{\text{gcalc}} := \left[ \frac{\text{DS1GR} \cdot E_1 - (\Delta H + Q1_{\text{Con}} + Q2_{\text{Con}})}{\text{DS1GR} \cdot \sigma} \right]^{0.25} \quad T_{\text{gcalc}} = 1759.16332 \text{ K}$$

Average assumed and calculated temperatures for next iteration

$$T_{\text{gnew}} := \frac{T_g + T_{\text{gcalc}}}{2} \quad T_{\text{gnew}} = 1759.1633222935 \text{ K} \quad \text{Go to Start}$$

END OF ITERATION LOOP: Final Gas Temperature  $T_g = 1759.16 \text{ K}$

$$\eta_g := \frac{H_{\text{in}} - H_{\text{out}}}{H_{\text{in}}} \quad \text{or} \quad \eta_{1g} := \frac{T_f - T_e}{T_f - T_0} \quad \eta_g = 0.43435 \quad \eta_{1g} = 0.43435$$

Heat flux density calculations:

$$q_1 := \frac{Q1_g + Q1_{\text{Con}}}{A_1} \quad q_{\text{tube}} := q_1 \cdot \left( 2 \cdot \frac{D_{\text{tube}}}{2 \cdot \pi \cdot D_{\text{tube}}} \right)$$

$$q_1 = 164.7 \frac{\text{kW}}{\text{m}^2} \quad q_{\text{tube}} = 52.44 \frac{\text{kW}}{\text{m}^2}$$

Note: This example was also solved with  $\Delta T_{\text{gr}} = 0$ . The results were as follows:  $T_f = 2552.8 \text{ K}$ ,  $T_r = T_e = 1707.1 \text{ K}$ ,  $T_2 = 1381.1 \text{ K}$ ,  $\eta_g = 37.51$  percent,  $D_{\text{eff}} = 0.53371$ , and  $\Delta H = 16332.7 \text{ kW}$ . The WSCC model with  $\Delta T_{\text{gr}} = 0$  predicts a lower performance bound.

Compare dimensionless WSCC model:

$$\Theta_0 := \frac{T_0}{T_f} \quad \Theta_1 := \frac{T_1}{T_f} \quad \Delta T_{\text{star}} := \frac{\Delta T_{\text{gr}}}{T_f}$$

$$T_{\text{gl}} := \frac{T_1 + T_g}{2}$$

$$\Theta_0 = 0.1155 \quad \Theta_1 = 0.3875 \quad \Delta T_{star} = 0.06588 \quad T_{g1} = 1379.58 \text{ K}$$

$$C_{P_{prod}} := \frac{MCp(T_c)}{MW_{in}} \quad C_{P_{prod}} = 0.000352 \text{ kW} \cdot \frac{\text{h}}{\text{kg} \cdot \text{K}}$$

$$N_{FD} := M_{dot} \frac{C_{P_{prod}}}{\sigma \cdot T_g^3 \cdot A_1} \quad N_{CR} := \frac{h_1}{4 \cdot \sigma \cdot T_{gl}^3} \quad D_{eff} := \frac{N_{FD}}{\frac{DSIGR}{A_1} + N_{CR}}$$

$$N_{FD} = 0.17176 \quad N_{CR} = 0.02855 \quad D_{eff} = 0.50409 \quad \frac{DSIGR}{A_1} = 0.31218$$

$$\eta_{prime} := \eta_g \cdot (1 - \Theta_0) \quad D1_{eff} := \frac{(1 + \Delta T_{star} - \eta_{prime})^4 - \Theta_1^4}{\eta_{prime}}$$

$$D1_{eff} = 0.50350 \quad \text{versus} \quad D_{eff} = 0.50409$$

This small discrepancy is due to linearization and neglect of convective refractory heat losses in the dimensionless WSCC model.

Compare dimensionless LPFF model:

$$R_{in} := \frac{1}{\Theta_1} \quad R_{in} = 2.58050$$

Trial and error calculation to match effective firing densities:  
Assume:

$$T_{out} := 1000.13763 \text{ K} \quad R_{out} := \frac{T_{out}}{T_1} \quad R_{out} = 1.00014 \quad \frac{4}{D_{eff}} = 7.93513$$

$$CLong := -\ln \left[ \frac{(R_{out} - 1) \cdot (R_{in} + 1)}{(R_{in} - 1) \cdot (R_{out} + 1)} \right] - 2 \cdot \text{atan} \left( \frac{R_{in} - R_{out}}{1 + R_{in} \cdot R_{out}} \right) \quad CLong = 7.93514$$

$$\eta_{L_f} := \frac{R_{in} - R_{out}}{R_{in} - 1} \quad \eta_{L_f} = 0.99991292 \quad \text{versus} \quad \eta_g = 0.43435$$

Note: The long plug flow furnace Model is so efficient that it would be grossly underfired using the computed WSCC effective firing density. Of the two models, the LPFF model always predicts an upper theoretical performance limit.

(This example was developed as a MATHCAD 14® worksheet. Mathcad is registered trademark of Parametric Technology Corporation.)

### WSCC Model Utility and More Complex Zoning Models

Despite its simplicity, the WSCC construct has a wide variety of practical uses and is of significant pedagogical value. Here an engineering situation of inordinate complexity is described by the definition of only eight dimensionless quantities  $D_{eff}$ ,  $N_{FD}$ ,  $\hat{S}_i G_R/A_1$ ,  $N_{CR}$ ,  $\eta_g$ ,  $\Delta^*$ ,  $\Theta_0$ , and  $\Theta_1$ . The first three are related by the simple algebraic definition  $D_{eff} = N_{FD}/(\hat{S}_i G_R/A_1 + N_{CR})$ . These dimensionless quantities con-

tain all the physical input information for the model, namely, furnace parameters and geometry, radiative properties of the combustion products, and the stoichiometry and thermodynamics of the combustion process. The WSCC model leads to a dimensionless two-dimensional plot of *reduced* effective furnace efficiency versus dimensionless effective firing density (Fig. 5-23), which is characterized by only two additional parameters, namely,  $\Delta^*$  and  $\Theta_1$ .

Of the models presented here, the WSCC model with  $\Delta T_{ge} = 0$  produces the lowest furnace efficiencies. The long furnace model usually produces the highest furnace efficiency. This is really not a fair statement because two distinctly different pieces of process equipment are compared. In this regard, a more appropriate definition of the dimensionless firing density for the LPFF model might be  $N'_{FD} = \dot{m} \bar{C}_p / (\sigma \cdot T_{g,in}^3 \cdot A_1)$ . It may be counterintuitive, but the WSCC and LPFF models *generally do not* characterize the extreme conditions for the performance of combustors as in the case of chemical reactors.

Figure 5-23 has been used to correlate furnace performance data for a multitude of industrial furnaces and combustors. Typical operational domains for a variety of fuel-fired industrial furnaces are summarized in Table 5-7. The WSCC approach (or "speckled" furnace model) is a classic contribution to furnace design methodology which was first due to Hottel [op. cit.]. The WSCC model provides a simple *furnace design template* which leads to a host of more complex furnace models. These models include an obvious extension to a tanks-in-series model as well as multizone models utilizing empirical cold-flow velocity patterns. For more information on practical furnace design models, reference is made to Hottel and Sarofim (op. cit., Chap. 14). Qualitative aspects of process equipment have been treated in some detail elsewhere (Baukal, C. E., ed., *The John Zink Combustion Handbook*, CRC Press, Boca Raton, Fla., 2001).

TABLE 5-7 Operational Domains for Representative Process Furnaces and Combustors

| Domain | Furnace or combustor type  | Dimensionless sink temperature | Dimensionless firing density |
|--------|--|--------------------------------|------------------------------|
| A      | Oil processing furnaces; radiant section of oil tube stills and cracking coils | $\Theta_1 \approx 0.4$         | $0.1 < D_{eff} < 1.0$        |
| B      | Domestic boiler combustion chambers  | $\Theta_1 \approx 0.2$         | $0.5 < D_{eff} < 1.1$        |
| C      | Glass furnaces   | $0.7 < \Theta_1 < 0.8$         | $0.035 < D_{eff} < 0.8$      |
| D      | Soaking pits   | $\Theta_1 \approx 0.6$         | $0.7 < D_{eff} < 1.1$        |
| E      | Gas-turbine combustors   | $0.4 < \Theta_1 < 0.7$         | $4.0 < D_{eff} < 25.0$       |

## INTRODUCTION

This part of Sec. 5 provides a concise guide to solving problems in situations commonly encountered by chemical engineers. It deals with diffusivity and mass-transfer coefficient estimation and common flux equations, although material balances are also presented in typical coordinate systems to permit a wide range of problems to be formulated and solved.

Mass-transfer calculations involve transport properties, such as diffusivities, and other empirical factors that have been found to relate mass-transfer rates to measured “driving forces” in myriad geometries and conditions. The context of the problem dictates whether the fundamental or more applied coefficient should be used. One key distinction is that, whenever there is flow parallel to an interface through which mass transfer occurs, the relevant coefficient is an empirical combination of properties and conditions. Conversely, when diffusion occurs in stagnant media or in creeping flow without transverse velocity gradients, ordinary diffusivities may be suitable for solving the problem. In either case, it is strongly suggested to employ data, whenever available, instead of relying on correlations.

Units employed in diffusivity correlations commonly followed the cgs system. Similarly, correlations for mass transfer correlations used the cgs or English system. In both cases, only the most recent correlations employ SI units. Since most correlations involve other properties and physical parameters, often with mixed units, they are repeated here as originally stated. Common conversion factors are listed in Table 1-4.

**Fick's First Law** This law relates flux of a component to its composition gradient, employing a constant of proportionality called a diffusivity. It can be written in several forms, depending on the units and frame of reference. Three that are related but not identical are

$$vJ_A = -D_{AB} \frac{dc_A}{dz} \approx mJ_A = -cD_{AB} \frac{dx_A}{dz} \approx mJ_A = -\rho D_{AB} \frac{dw_A}{dz} \quad (5-189)$$

The first equality (on the left-hand side) corresponds to the molar flux with respect to the volume average velocity, while the equality in the center represents the molar flux with respect to the molar average velocity and the one on the right is the mass flux with respect to the mass average velocity. These must be used with consistent flux expressions for fixed coordinates and for  $N_C$  components, such as:

$$N_A = vJ_A + c_A \sum_{i=1}^{N_C} N_i \bar{V}_i = mJ_A + x_A \sum_{i=1}^{N_C} N_i = \frac{mJ_A + w_A \sum_{i=1}^{N_C} n_i}{M_A} \quad (5-190)$$

In each case, the term containing the summation accounts for *conveyance*, which is the amount of component  $A$  carried by the net flow in the direction of diffusion. Its impact on the total flux can be as much as 10 percent. In most cases it is much less, and it is frequently ignored. Some people refer to this as the “convective” term, but that conflicts with the other sense of convection which is promoted by flow perpendicular to the direction of flux.

**Mutual Diffusivity, Mass Diffusivity, Interdiffusion Coefficient** Diffusivity is denoted by  $D_{AB}$  and is defined by Fick's first law as the ratio of the flux to the concentration gradient, as in Eq. (5-189). It is analogous to the thermal diffusivity in Fourier's law and to the kinematic viscosity in Newton's law. These analogies are flawed because both heat and momentum are conveniently defined with respect to fixed coordinates, irrespective of the direction of transfer or its magnitude, while mass diffusivity most commonly requires infor-

mation about bulk motion of the medium in which diffusion occurs. For liquids, it is common to refer to the limit of infinite dilution of  $A$  in  $B$  using the symbol,  $D_{AB}^\circ$ .

When the flux expressions are consistent, as in Eq. (5-190), the diffusivities in Eq. (5-189) are identical. As a result, experimental diffusivities are often measured under constant volume conditions but may be used for applications involving open systems. It turns out that the two versions are very nearly equivalent for gas-phase systems because there is negligible volume change on mixing. That is not usually true for liquids, however.

**Self-Diffusivity** Self-diffusivity is denoted by  $D_{AA}$  and is the measure of mobility of a species in itself; for instance, using a small concentration of molecules tagged with a radioactive isotope so they can be detected. Tagged and untagged molecules presumably do not have significantly different properties. Hence, the solution is ideal, and there are practically no gradients to “force” or “drive” diffusion. This kind of diffusion is presumed to be purely statistical in nature.

In the special case that  $A$  and  $B$  are similar in molecular weight, polarity, and so on, the self-diffusion coefficients of pure  $A$  and  $B$  will be approximately equal to the mutual diffusivity,  $D_{AB}$ . Second, when  $A$  and  $B$  are the less mobile and more mobile components, respectively, their self-diffusion coefficients can be used as rough lower and upper bounds of the mutual diffusion coefficient. That is,  $D_{AA} \leq D_{AB} \leq D_{BB}$ . Third, it is a common means for evaluating diffusion for gases at high pressure. Self-diffusion in liquids has been studied by many [Easteal, *AIChE J.* **30**, 641 (1984), Ertl and Dullien, *AIChE J.* **19**, 1215 (1973), and Vadovic and Colver, *AIChE J.* **18**, 1264 (1972)].

**Tracer Diffusivity** Tracer diffusivity, denoted by  $D_{A'B}$  is related to both mutual and self-diffusivity. It is evaluated in the presence of a second component  $B$ , again using a tagged isotope of the first component. In the dilute range, tagging  $A$  merely provides a convenient method for indirect composition analysis. As concentration varies, tracer diffusivities approach mutual diffusivities at the dilute limit, and they approach self-diffusivities at the pure component limit. That is, at the limit of dilute  $A$  in  $B$ ,  $D_{A'B} \rightarrow D_{AB}^\circ$  and  $D_{B'A} \rightarrow D_{B'B}^\circ$ ; likewise at the limit of dilute  $B$  in  $A$ ,  $D_{B'A} \rightarrow D_{BA}^\circ$  and  $D_{A'B} \rightarrow D_{A'A}^\circ$ .

Neither the tracer diffusivity nor the self-diffusivity has much practical value except as a means to understand ordinary diffusion and as order-of-magnitude estimates of mutual diffusivities. Darken's equation [Eq. (5-230)] was derived for tracer diffusivities but is often used to relate mutual diffusivities at moderate concentrations as opposed to infinite dilution.

**Mass-Transfer Coefficient** Denoted by  $k_c$ ,  $k_x$ ,  $K_c$ , and so on, the mass-transfer coefficient is the ratio of the flux to a concentration (or composition) difference. These coefficients generally represent rates of transfer that are much greater than those that occur by diffusion alone, as a result of convection or turbulence at the interface where mass transfer occurs. There exist several principles that relate that coefficient to the diffusivity and other fluid properties and to the intensity of motion and geometry. Examples that are outlined later are the film theory, the surface renewal theory, and the penetration theory, all of which pertain to idealized cases. For many situations of practical interest like investigating the flow inside tubes and over flat surfaces as well as measuring external flow through banks of tubes, in fixed beds of particles, and the like, correlations have been developed that follow the same forms as the above theories. Examples of these are provided in the subsequent section on mass-transfer coefficient correlations.

**Problem Solving Methods** Most, if not all, problems or applications that involve mass transfer can be approached by a systematic course of action. In the simplest cases, the unknown quantities are obvious. In more complex (e.g., multicomponent, multiphase, multi-dimensional, nonisothermal, and/or transient) systems, it is more subtle to resolve the known and unknown quantities. For example, in multicomponent systems, one must know the fluxes of the components before predicting their effective diffusivities and vice versa. More will be said about that dilemma later. Once the known and unknown quantities are resolved, however, a combination of conservation equations, definitions, empirical relations, and properties are

Nomenclature and Units—Mass Transfer

| Symbols         | Definition  | SI units  | U.S. Customary units   |
|-----------------|---|---|--|
| $a$             | Effective interfacial mass transfer area per unit volume                        | $m^2/m^3$   | $ft^2/ft^3$  |
| $A_s$           | Cross-sectional area of vessel  | $m^2$ or $cm^2$   | $ft^2$   |
| $A'$            | Constant (see Table 5-24-K)   |   |  |
| $a_p$           | See $a$   |   |  |
| $c$             | Concentration = $P/RT$ for an ideal gas   | $mol/m^3$ or $mol/l$ or $gequiv/l$                          | $lbmol/ft^3$   |
| $c_i$           | Concentration of component $i = x, c$ at gas-liquid interface                   | $mol/m^3$ or $mol/l$ or $gequiv/l$                          | $lbmol/ft^3$   |
| $c_p$           | Specific heat   | $kJ/(kg \cdot K)$   | $Btu/(lb \cdot ^\circ F)$  |
| $d$             | Characteristic length   | $m$ or $cm$   | $ft$   |
| $d_b$           | Bubble diameter   | $m$   | $ft$   |
| $d_c$           | Column diameter   | $m$ or $cm$   | $ft$   |
| $d_{drop}$      | Sauter mean diameter  | $m$   | $ft$   |
| $d_{imp}$       | Impeller diameter   | $m$   | $ft$   |
| $d_{pore}$      | Pore diameter   | $m$ or $cm$   | $ft$   |
| $D_{A,A}$       | Self-diffusivity ( $= D_A$ at $x_A = 1$ )                                       | $m^2/s$ or $cm^2/s$   | $ft^2/h$   |
| $D_{AB}$        | Mutual diffusivity  | $m^2/s$ or $cm^2/s$   | $ft^2/h$   |
| $D_{AB}^\infty$ | Mutual diffusivity at infinite dilution of $A$ in $B$                           | $m^2/s$ or $cm^2/s$   | $ft^2/h$   |
| $D_{eff}$       | Effective diffusivity within a porous solid $= \epsilon_p D/\tau$               | $m^2/s$   | $ft^2/h$   |
| $D_K$           | Knudson diffusivity for gases in small pores                                    | $m^2/s$ or $cm^2/s$   | $ft^2/h$   |
| $D_L$           | Liquid phase diffusion coefficient  | $m^2/s$   | $ft^2/h$   |
| $D_s$           | Surface diffusivity   | $m^2/s$ or $cm^2/s$   | $ft^2/h$   |
| $E$             | Energy dissipation rate/mass  |   |  |
| $E_s$           | Activation energy for surface diffusion   | $J/mol$ or $cal/mol$  |  |
| $f$             | Friction factor for fluid flow  | Dimensionless   | Dimensionless  |
| $F$             | Faraday's constant  | $96,487$ Coulomb/gequiv                                     |  |
| $g$             | Acceleration due to gravity   | $m/s^2$   | $ft/h^2$   |
| $g_c$           | Conversion factor   | $1.0$   | $4.17 \times 10^8$ lb ft/[lbf-h <sup>2</sup> ]   |
| $G$             | Gas-phase mass flux   | $kg/(s \cdot m^2)$  | $lb/(h \cdot ft^2)$  |
| $G_a$           | Dry air flux  | $kg/(s \cdot m^2)$  | $lb/(h \cdot ft^2)$  |
| $G_M$           | Molar gas-phase mass flux   | $kmol/(s \cdot m^2)$  | $(lbmol)/(h \cdot ft^2)$   |
| $h'$            | Heat transfer coefficient   | $W/(m^2 \cdot K) = J/(s \cdot m^2 \cdot K)$                 | $Btu/(h \cdot ft^2 \cdot ^\circ F)$  |
| $h_T$           | Total height of tower packing   | $m$   | $ft$   |
| $H$             | Compartment height  | $m$   | $ft$   |
| $H$             | Henry's law constant  | $kPa/(mole-fraction solute in liquid phase)$                | $(lbf/in^2)/(mole-fraction solute in liquid phase)$  |
| $H'$            | Henry's law constant  | $kPa/[kmol/(m^3 \text{ solute in liquid phase})]$           | $(lbf/in^2)/[(lbmol)/(ft^3 \text{ solute in liquid phase})]$ or $atm/[(lbmole)/(ft^3 \text{ solute in liquid phase})]$ |
| $H_G$           | Height of one transfer unit based on gas-phase resistance                       | $m$   | $ft$   |
| $H_{OG}$        | Height of one overall gas-phase mass-transfer unit                              | $m$   | $ft$   |
| $H_L$           | Height of one transfer unit based on liquid-phase resistance                    | $m$   | $ft$   |
| $H_{OL}$        | Height of one overall liquid-phase mass-transfer unit                           | $m$   | $ft$   |
| $HTU$           | Height of one transfer unit (general)   | $m$   | $ft$   |
| $j_D$           | Chilton-Colburn factor for mass transfer, Eq. (5-289)                           | Dimensionless   | Dimensionless  |
| $j_H$           | Chilton-Colburn factor for heat transfer  | Dimensionless   | Dimensionless  |
| $j_M$           | See $j_D$   |   |  |
| $m_{JA}$        | Mass flux of $A$ by diffusion with respect to the mean mass velocity            | $kmol/(m^2 \cdot s)$ or $mol/(cm^2 \cdot s)$                | $lbmol/(ft^2 \cdot h)$   |
| $M_{JA}$        | Molar flux of $A$ by diffusion with respect to mean molar velocity              | $kmol/(m^2 \cdot s)$ or $mol/(cm^2 \cdot s)$                | $lbmol/(ft^2 \cdot h)$   |
| $v_{JA}$        | Molar flux of $A$ with respect to mean volume velocity                          | $kmol/(m^2 \cdot s)$  | $lbmol/(ft^2 \cdot h)$   |
| $J_{si}$        | Molar flux by surface diffusion   | $kmol/(m^2 \cdot s)$ or $gmol/(cm^2 \cdot s)$               | $lbmol/(ft^2 \cdot h)$   |
| $k$             | Boltzmann's constant  | $8.9308 \times 10^{-10}$ gequiv ohm/s                       |  |
| $k$             | Film mass transfer coefficient  | $m/s$ or $cm/s$   | $ft/hr$  |
| $k$             | Thermal conductivity  | $(J \cdot m)/(s \cdot m^2 \cdot K)$                         | $Btu/(h \cdot ft \cdot ^\circ F)$  |
| $k'$            | Mass-transfer coefficient for dilute systems                                    | $kmol/[(s \cdot m^2)(kmol/m^3)]$ or $m/s$                   | $lbmol/[(h \cdot ft^2)(lbmol/ft^3)]$ or $ft/hr$  |
| $k_G$           | Gas-phase mass-transfer coefficient for dilute systems                          | $kmol/[(s \cdot m^2)(kPa \text{ solute partial pressure})]$ | $lbmol/[(h \cdot ft^2)lbf/in^2 \text{ solute partial pressure}]$   |
| $K_G$           | Gas-phase mass-transfer coefficient for dilute systems                          | $kmol/[(s \cdot m^2)(mole fraction in gas)]$                | $lbmol/[(h \cdot ft^2)(mole fraction in gas)]$   |
| $k_{GA}$        | Volumetric gas-phase mass-transfer coefficient for concentrated systems         | $kmol/[(s \cdot m^3)(mole fraction)]$                       | $(lbmol)/[(h \cdot ft^3)(mole fraction)]$  |
| $\hat{k}_{GA}$  | Overall volumetric gas-phase mass-transfer coefficient for concentrated systems | $kmol/(s \cdot m^3)$  | $lbmol/(h \cdot ft^3)$   |
| $\hat{k}_L'$    | Liquid phase mass transfer coefficient for pure absorption (no reaction)        | $kmol/(s \cdot m^2)$  | $lbmol/(h \cdot ft^2)$   |
| $k_L$           | Liquid-phase mass-transfer coefficient for dilute systems                       | $kmol/[(s \cdot m^2)(mole-fraction solution in liquid)]$    | $(lbmol)/[(h \cdot ft^2)(mole-fraction solute in liquid)]$   |
| $k_L'$          | Liquid-phase mass-transfer coefficient for dilute systems                       | $kmol/[(s \cdot m^2)(kmol/m^3)]$ or $m/s$                   | $(lbmol)/[(h \cdot ft^2)(lbmol/ft^3)]$ or $ft/h$   |
| $\hat{k}_L$     | Liquid-phase mass-transfer coefficient for concentrated systems                 | $kmol/(s \cdot m^2)$  | $lbmol/(h \cdot ft^2)$   |
| $k_{LA}$        | Volumetric liquid-phase mass-transfer coefficient for dilute systems            | $kmol/[(s \cdot m^3)(mole fraction)]$                       | $(lbmol)/[(h \cdot ft^3)(mole fraction)]$  |
| $K$             | Overall mass transfer coefficient   | $m/s$ or $cm/s$   | $ft/h$   |
| $K$             | $\alpha/R =$ specific conductance   | $ohm/cm$  |  |
| $K_G$           | Overall gas-phase mass-transfer coefficient for dilute systems                  | $kmol/[(s \cdot m^2)(mole fraction)]$                       | $(lbmol)/[(h \cdot ft^2)(mole fraction)]$  |

**Nomenclature and Units—Mass Transfer (Continued)**

| Symbols        | Definition   | SI units   | U.S. Customary units  |
|----------------|--|--|---|
| $\hat{K}_G$    | Overall gas-phase mass-transfer coefficient for concentrated systems                                 | kmol/(s·m <sup>2</sup> )   | lbmol/(h·ft <sup>2</sup> )  |
| $K_{Ga}$       | Overall volumetric gas-phase mass-transfer dilute systems  | kmol/[(s·m <sup>3</sup> )(mole-fraction solute in gas)]                              | (lbmol)/[(h·ft <sup>3</sup> )(mole-fraction solute in gas)]                 |
| $K'_{Ga}$      | Overall volumetric gas-phase mass-transfer dilute systems  | kmol/[(s·m <sup>3</sup> )(kPa solute partial pressure)]                              | (lbmol)/[(h·ft <sup>3</sup> )(lbf/in <sup>2</sup> solute partial pressure)] |
| $(Ka)_H$       | Overall enthalpy mass-transfer coefficient   | kmol/[(s·m <sup>2</sup> )(mole fraction)]  | lb/[(h·ft <sup>2</sup> )(lb water/lb dry air)]                              |
| $K_L$          | Overall liquid-phase mass-transfer coefficient   | kmol/[(s·m <sup>2</sup> )(mole fraction)]  | (lbmol)/[(h·ft <sup>2</sup> )(mole fraction)]                               |
| $\hat{K}_L$    | Liquid-phase mass-transfer coefficient for concentrated systems                                      | kmol/(s·m <sup>2</sup> )   | (lbmol)/(h·ft <sup>2</sup> )  |
| $K_{La}$       | Overall volumetric liquid-phase mass-transfer coefficient for dilute systems                         | kmol/[(s·m <sup>3</sup> )(mole-fraction solute in liquid)]                           | (lbmol)/[(h·ft <sup>3</sup> )(mole-fraction solute in liquid)]              |
| $\hat{K}_{La}$ | Overall volumetric liquid-phase mass-transfer coefficient for concentrated systems                   | kmol/(s·m <sup>3</sup> )   | (lbmol)/(h·ft <sup>3</sup> )  |
| $L$            | Liquid-phase mass flux   | kg/(s·m <sup>2</sup> )   | lb/(h·ft <sup>2</sup> )   |
| $L_M$          | Molar liquid-phase mass flux   | kmol/(s·m <sup>2</sup> )   | (lbmol)/(h·ft <sup>2</sup> )  |
| $m$            | Slope of equilibrium curve = $dy/dx$ (mole-fraction solute in gas)/(mole-fraction solute in liquid)  | Dimensionless  | Dimensionless   |
| $m$            | Molality of solute   | mol/1000 g solvent   |   |
| $M_i$          | Molecular weight of species $i$  | kg/kmol or g/mol   | lb/lbmol  |
| $M$            | Mass in a control volume $V$   | kg or g  | lb  |
| $ n_+ ,  n_- $ | Valences of cationic and anionic species   | Dimensionless  | Dimensionless   |
| $n'$           | See Table 5-24-K   | Dimensionless  | Dimensionless   |
| $n_A$          | Mass flux of $A$ with respect to fixed coordinates   | kg/(s·m <sup>2</sup> )   | lb/(h·ft <sup>2</sup> )   |
| $N$            | Impeller speed   | Revolution/s   | Revolution/min  |
| $N'$           | Number deck levels   | Dimensionless  | Dimensionless   |
| $N_A$          | Interphase mass-transfer rate of solute $A$ per interfacial area with respect to fixed coordinates   | kmol/(s·m <sup>2</sup> )   | (lbmol)/(h·ft <sup>2</sup> )  |
| $N_c$          | Number of components   | Dimensionless  | Dimensionless   |
| $N_{Fr}$       | Froude Number ( $d_{imp} N^2/g$ )  | Dimensionless  | Dimensionless   |
| $N_{Gr}$       | Grashof number $\left(\frac{g x^3}{(\mu/\rho)^2} \left(\frac{\rho_\infty}{\rho_s} - 1\right)\right)$ | Dimensionless  | Dimensionless   |
| $N_{OG}$       | Number of overall gas-phase mass-transfer units  | Dimensionless  | Dimensionless   |
| $N_{OL}$       | Number of overall liquid-phase mass-transfer units   | Dimensionless  | Dimensionless   |
| NTU            | Number of transfer units (general)   | Dimensionless  | Dimensionless   |
| $N_{Kn}$       | Knudson number = $l/d_{pore}$  | Dimensionless  | Dimensionless   |
| $N_{Pr}$       | Prandtl number ( $c_p \mu/k$ )   | Dimensionless  | Dimensionless   |
| $N_{Re}$       | Reynolds number ( $Gd/\mu_G$ )   | Dimensionless  | Dimensionless   |
| $N_{Sc}$       | Schmidt number ( $\mu_G/\rho_G D_{AB}$ ) or ( $\mu_L/\rho_L D_L$ )                                   | Dimensionless  | Dimensionless   |
| $N_{Sh}$       | Sherwood number ( $k_c R T d / D_{AB} p_T$ ), see also Tables 5-17 to 5-24                           | Dimensionless  | Dimensionless   |
| $N_{St}$       | Stanton number ( $k_c / G_M$ ) or ( $k_L / L_M$ )  | Dimensionless  | Dimensionless   |
| $N_{We}$       | Weber number ( $\rho N^2 d_{imp}^3 / \sigma$ )   | Dimensionless  | Dimensionless   |
| $p$            | Solute partial pressure in bulk gas  | kPa  | lbf/in <sup>2</sup>   |
| $p_{B,M}$      | Log mean partial pressure difference of stagnant gas $B$   | Dimensionless  | Dimensionless   |
| $p_i$          | Solute partial pressure at gas-liquid interface  | kPa  | lbf/in <sup>2</sup>   |
| $p_T$          | Total system pressure  | kPa  | lbf/in <sup>2</sup>   |
| $P$            | Pressure   | Pa   | lbf/in <sup>2</sup> or atm  |
| $P$            | Power  | Watts  |   |
| $P_c$          | Critical pressure  | Pa   | lbf/in <sup>2</sup> or atm  |
| Per            | Perimeter/area   | m <sup>-1</sup>  | ft <sup>-1</sup>  |
| $Q$            | Volumetric flow rate   | m <sup>3</sup> /s  | ft <sup>3</sup> /h  |
| $r_A$          | Radius of dilute spherical solute  | Å  |   |
| $R$            | Gas constant   | 8.314 J/mol K = 8.314 Pa m <sup>3</sup> /(mol K) = 82.057 atm cm <sup>3</sup> /mol K | 10.73 ft <sup>3</sup> psia/lbmol·h  |
| $R$            | Solution electrical resistance   | ohm  |   |
| $R_i$          | Radius of gyration of the component $i$ molecule   | Å  |   |
| $s$            | Fractional surface-renewal rate  | s <sup>-1</sup>  | h <sup>-1</sup>   |
| $S$            | Tower cross-sectional area = $\pi d^2/4$   | m <sup>2</sup>   | ft <sup>2</sup>   |
| $t$            | Contact time   | s  | h   |
| $t_f$          | Formation time of drop   | s  | h   |
| $T$            | Temperature  | K  | °R  |
| $T_b$          | Normal boiling point   | K  | °R  |
| $T_c$          | Critical temperature   | K  | °R  |
| $T_r$          | Reduced temperature = $T/T_c$  | Dimensionless  | Dimensionless   |
| $u, v$         | Fluid velocity   | m/s or cm/s  | ft/h  |
| $u_o$          | Blowing or suction velocity  | m/s  | ft/h  |
| $u_\infty$     | Velocity away from object  | m/s  | ft/h  |
| $u_L$          | Superficial liquid velocity in vertical direction  | m/s  | ft/h  |
| $v_s$          | Slip velocity  | m/s  | ft/h  |
| $v_T$          | Terminal velocity  | m/s  | ft/h  |
| $v_{TS}$       | Stokes law terminal velocity   | m/s  | ft/h  |
| $V$            | Packed volume in tower   | m <sup>3</sup>   | ft <sup>3</sup>   |
| $V$            | Control volume   | m <sup>3</sup> or cm <sup>3</sup>  | ft <sup>3</sup>   |
| $V_b$          | Volume at normal boiling point   | m <sup>3</sup> /kmol or cm <sup>3</sup> /mol   | ft <sup>3</sup> /lbmol  |
| $V_i$          | Molar volume of $i$ at its normal boiling point  | m <sup>3</sup> /kmol or cm <sup>3</sup> /mol   | ft <sup>3</sup> /lbmol  |
| $\bar{v}_i$    | Partial molar volume of $i$  | m <sup>3</sup> /kmol or cm <sup>3</sup> /mol   | ft <sup>3</sup> /lbmol  |

## 5-48 HEAT AND MASS TRANSFER

### Nomenclature and Units—Mass Transfer (Concluded)

| Symbols               | Definition   | SI units   | U.S. Customary units                           |
|-----------------------|--|--|--|
| $V_{mli}$             | Molar volume of the liquid-phase component $i$ at the melting point  | $m^3/\text{kmol}$ or $\text{cm}^3/\text{mol}$    | $\text{ft}^3/\text{lbmol}$                     |
| $V_{\text{tower}}$    | Tower volume per area  | $m^3/m^2$  | $\text{ft}^3/\text{ft}^2$                      |
| $w$                   | Width of film  | $m$  | $\text{ft}$                                    |
| $x$                   | Length along plate   | $m$  | $\text{ft}$                                    |
| $x$                   | Mole-fraction solute in bulk-liquid phase  | $(\text{kmol solute})/(\text{kmol liquid})$      | $(\text{lbmol solute})/(\text{lb mol liquid})$ |
| $x_A$                 | Mole fraction of component A   | $\text{kmole A}/\text{kmole fluid}$              | $\text{lbmol A}/\text{lb mol fluid}$           |
| $x^o$                 | Mole-fraction solute in bulk liquid in equilibrium with bulk-gas solute concentration $y$                            | $(\text{kmol solute})/(\text{kmol liquid})$      | $(\text{lbmol solute})/(\text{lbmol liquid})$  |
| $x_{BM}$              | Logarithmic-mean solvent concentration between bulk liquid and interface values                                      | $(\text{kmol solvent})/(\text{kmol liquid})$     | $(\text{lbmol solvent})/(\text{lbmol liquid})$ |
| $x_{BM}^o$            | Logarithmic-mean inert-solvent concentration between bulk-liquid value and value in equilibrium with bulk gas        | $(\text{kmol solvent})/(\text{kmol liquid})$     | $(\text{lbmol solvent})/(\text{lbmol liquid})$ |

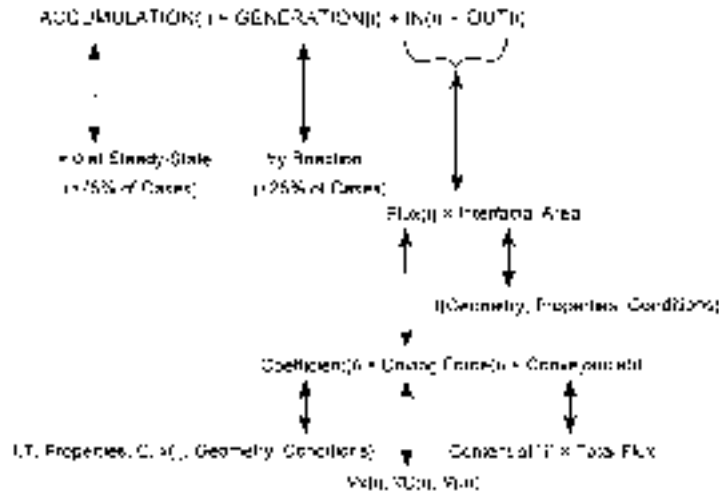

FIG. 5-24 Flowchart illustrating problem solving approach using mass-transfer rate expressions in the context of mass conservation.

applied to arrive at an answer. Figure 5-24 is a flowchart that illustrates the primary types of information and their relationships, and it applies to many mass-transfer problems.

**CONTINUITY AND FLUX EXPRESSIONS**

**Material Balances** Whenever mass-transfer applications involve equipment of specific dimensions, flux equations alone are inadequate to assess results. A material balance or continuity equation must also be used. When the geometry is simple, macroscopic balances suffice. The following equation is an overall mass balance for such a unit having  $N_m$  bulk-flow ports and  $N_n$  ports or interfaces through which diffusive flux can occur:

$$\frac{dM}{dt} = \sum_{i=1}^{N_m} m_i + \sum_{i=1}^{N_n} n_i A_{cs_i} \tag{5-191}$$

where  $M$  represents the mass in the unit volume  $V$  at any time  $t$ ;  $m_i$  is the mass flow rate through the  $i$ th port; and  $n_i$  is the mass flux through the  $i$ th port, which has a cross-sectional area of  $A_{cs_i}$ . The corresponding balance equation for individual components includes a reaction term:

$$\frac{dM_j}{dt} = \sum_{i=1}^{N_m} m_{ij} + \sum_{i=1}^{N_n} n_{ij} A_{cs_i} + r_j V \tag{5-192}$$

For the  $j$ th component,  $m_{ij} = m_i w_{ij}$  is the component mass flow rate in stream  $i$ ;  $w_{ij}$  is the mass fraction of component  $j$  in stream  $i$ ; and  $r_j$  is the net reaction rate (mass generation minus consumption) per unit volume  $V$  that contains mass  $M$ . If it is inconvenient to measure mass flow rates, the product of density and volumetric flow rate is used instead.

In addition, most situations that involve mass transfer require material balances, but the pertinent area is ambiguous. Examples are packed columns for absorption, distillation, or extraction. In such

cases, flow rates through the discrete ports (nozzles) must be related to the mass-transfer rate in the packing. As a result, the mass-transfer rate is determined via flux equations, and the overall material balance incorporates the stream flow rates  $m_i$  and integrated fluxes. In such instances, it is common to begin with the most general, differential material balance equations. Then, by eliminating terms that are negligible, the simplest applicable set of equations remains to be solved. Table 5-8 provides material balances for Cartesian, cylindrical, and spherical coordinates. The generic form applies over a unit cross-sectional area and constant volume:

$$\frac{\partial \rho_j}{\partial t} = -\nabla \cdot n_j + r_j \tag{5-193a}$$

where  $n_j = \rho v_j$ . Applying Fick's law and expressing composition as concentration gives

$$\frac{\partial c_j}{\partial t} = -v \cdot \nabla c_j + D_j \nabla^2 c_j + r_j \tag{5-193b}$$

**Flux Expressions: Simple Integrated Forms of Fick's First Law** Simplified flux equations that arise from Eqs. (5-189) and (5-190) can be used for unidimensional, steady-state problems with binary mixtures. The boundary conditions represent the compositions  $x_{A_L}$  and  $x_{A_R}$  at the left-hand and right-hand sides of a hypothetical layer having thickness  $\Delta z$ . The principal restriction of the following equations is that the concentration and diffusivity are assumed to be constant. As written, the flux is positive from left to right, as depicted in Fig. 5-25.

1. Equimolar counterdiffusion ( $N_A = -N_B$ )

$$N_A = M J_A = -D_{AB} c \frac{dx_A}{dz} = \frac{D_{AB}}{\Delta z} c (x_{A_L} - x_{A_R}) \tag{5-197}$$

TABLE 5-8 Continuity Equation in Various Coordinate Systems

| Coordinate System | Equation   |
|-------------------|--|
| Cartesian         | $\frac{\partial \rho_j}{\partial t} = -\left(\frac{\partial n_{x_j}}{\partial x} + \frac{\partial n_{y_j}}{\partial y} + \frac{\partial n_{z_j}}{\partial z}\right) + r_j$ (5-194)   |
| Cylindrical       | $\frac{\partial \rho_j}{\partial t} = -\left(\frac{1}{r} \frac{\partial m_{r_j}}{\partial r} + \frac{1}{r} \frac{\partial n_{\theta_j}}{\partial \theta} + \frac{\partial n_{z_j}}{\partial z}\right) + r_j$ (5-195)   |
| Spherical         | $\frac{\partial \rho_j}{\partial t} = -\left(\frac{1}{r^2} \frac{\partial r^2 n_{r_j}}{\partial r} + \frac{1}{r \sin \theta} \frac{\partial n_{\theta_j} \sin \theta}{\partial \theta} + \frac{1}{r \sin \theta} \frac{\partial n_{\phi_j}}{\partial \phi}\right) + r_j$ (5-196) |

FIG. 5-25 Hypothetical film and boundary conditions.

2. Unimolar diffusion ( $N_A \neq 0, N_B = 0$ )

$$N_A = M J_A + x_A N_A = \frac{D_{AB}}{\Delta z} c \ln \frac{1 - x_{A_R}}{1 - x_{A_L}} \quad (5-198)$$

3. Steady state diffusion ( $N_A \neq -N_B \neq 0$ )

$$N_A = M J_A + x_A (N_A + N_B) = \frac{N_A}{N_A + N_B} \frac{D_{AB}}{\Delta z} c \ln \frac{\frac{N_A}{N_A + N_B} - x_{A_R}}{\frac{N_A}{N_A + N_B} - x_{A_L}} \quad (5-199)$$

The unfortunate aspect of the last relationship is that one must know a priori the ratio of the fluxes to determine the magnitudes. It is not possible to solve simultaneously the pair of equations that apply for components *A* and *B* because the equations are not independent.

**Stefan-Maxwell Equations** Following Eq. (5-190), a simple and intuitively appealing flux equation for applications involving  $N_c$  components is

$$N_i = -c D_{im} \nabla x_i + x_i \sum_{j=1}^{N_c} N_j \quad (5-200)$$

In the late 1800s, the development of the kinetic theory of gases led to a method for calculating multicomponent gas diffusion (e.g., the flux of each species in a mixture). The methods were developed simultaneously by Stefan and Maxwell. The problem is to determine the diffusion coefficient  $D_{im}$ . The Stefan-Maxwell equations are simpler in principle since they employ binary diffusivities:

$$\nabla x_i = \sum_{j=1}^{N_c} \frac{1}{c D_{ij}} (x_i N_j - x_j N_i) \quad (5-201)$$

If Eqs. (5-200) and (5-201) are combined, the multicomponent diffusion coefficient may be assessed in terms of binary diffusion coefficients [see Eq. (5-214)]. For gases, the values  $D_{ij}$  of this equation are approximately equal to the binary diffusivities for the *ij* pairs. The Stefan-Maxwell diffusion coefficients may be negative, and the method may be applied to liquids, even for electrolyte diffusion [Kraaijeveld, Wesselingh, and Kuiken, *Ind. Eng. Chem. Res.*, **33**, 750 (1994)]. Approximate solutions have been developed by linearization [Toor, H.L., *AIChE J.*, **10**, 448 and 460 (1964); Stewart and Prober, *Ind. Eng. Chem. Fundam.*, **3**, 224 (1964)]. Those differ in details but yield about the same accuracy. More recently, efficient algorithms for solving the equations exactly have been developed (see Taylor and Krishna, Krishnamurthy and Taylor [*Chem. Eng. J.*, **25**, 47 (1982)], and Taylor and Webb [*Comput. Chem. Eng.*, **5**, 61 (1981)]).

Useful studies of multicomponent diffusion were presented by Vrentas and Vrentas [*Ind. Eng. Chem. Res.*, **44**, 1112 (2005)], Curtis

and Bird [*Ind. Eng. Chem. Res.*, **38**, 2515 (1999)], and Amundson, Pan, and Paulson [*AIChE J.*, **48**, 813 (2003)]. Vrentas and Vrentas treated only ternary mixtures, such as restrictions due to the entropy inequality, application of the Onsager reciprocal relations, and stability. Curtis and Bird reconciled the multicomponent Fick's law approach with the more elegant Stefan-Maxwell theory. They also provided interrelationships of multicomponent diffusivities devised for various situations, i.e., binary, ternary, and quaternary mixtures. Amundson et al. presented numerical methods for coping with mixtures having four or more components, which are nearly intractable via the analytical S-M method, due to the difficult inversion. Related studies were performed by Ghorayeb and Firoozabadi [*AIChE J.*, **46**, 883 (2000)] and Firoozabadi, Ghorayeb, and Saukla [*AIChE J.*, **46**, 892 (2000)]. The former covered ordinary molecular diffusion as well as pressure and thermal diffusion for multicomponent mixtures. The latter covered thermal diffusion in multicomponent mixtures.

## DIFFUSIVITY ESTIMATION—GASES

Whenever measured values of diffusivities are available, they should be used. Typically, measurement errors are less than those associated with predictions by empirical or even semitheoretical equations. A few general sources of data are Sec. 2 of this handbook; e.g., experimental values for gas mixtures are listed in Table 2-371. Estimation methods for some gaseous applications appear in Eqs. (2-150) through (2-154). Other pertinent references are Schwartzberg and Chao; Poling et al.; Gammon et al.; and Daubert and Danner. Many other more restricted sources are listed under specific topics later in this subsection.

Before using diffusivities from either data or correlations, it is a good idea to check their reasonableness with respect to values that have been commonly observed in similar situations. Table 5-9 is a compilation of several rules of thumb. These values are not authoritative; they simply represent guidelines based on experience.

Diffusivity correlations for gases are outlined in Table 5-10. Specific parameters for individual equations are defined in the specific text regarding each equation. References are given at the beginning of the "Mass Transfer" subsection. The errors reported for Eqs. (5-202) through (5-205) were compiled by Poling et al., who compared the predictions with 68 experimental values of  $D_{AB}$ . Errors cited for Eqs. (5-206) to (5-212) were reported by the authors.

**Binary Mixtures—Low Pressure—Nonpolar Components** Many evaluations of correlations are available [Elliott and Watts, *Can. J. Chem.*, **50**, 31 (1972); Lugg, *Anal. Chem.*, **40**, 1072 (1968); Marrero and Mason, *AIChE J.*, **19**, 498 (1973)]. The differences in accuracy of the correlations are minor, and thus the major concern is ease of calculation. The Fuller-Schettler-Giddings equation is usually the simplest correlation to use and is recommended by Poling et al.

**Chapman-Enskog (Bird et al.) and Wilke and Lee [31]** The inherent assumptions of these equations are quite restrictive (i.e., low density, spherical atoms), and the intrinsic potential function is empirical. Despite that, they provide good estimates of  $D_{AB}$  for many polyatomic gases and gas mixtures, up to about 1000 K and a maximum of 70 atm. The latter constraint is because observations for many gases indicate that  $D_{AB}P$  is constant up to 70 atm.

The characteristic length is  $\sigma_{AB} = (\sigma_A + \sigma_B)/2$  in Å. In order to estimate  $\Omega_D$  for Eq. (5-202) or (5-203), two empirical equations are

available. The first is:

$$\Omega_D = (44.54T^{0-4.909} + 1.911T^{0-1.575})^{0.10} \quad (5-213a)$$

where  $T^{\circ} = kT/\epsilon_{AB}$  and  $\epsilon_{AB} = (\epsilon_A \epsilon_B)^{1/2}$ . Estimates for  $\sigma_i$  and  $\epsilon_i$  are given in Table 5-11. This expression shows that  $\Omega_D$  is proportional to temperature roughly to the  $-0.49$  power at low temperatures and to the

$-0.16$  power at high temperature. Thus, gas diffusivities are proportional to temperatures to the 2.0 power and 1.66 power, respectively, at low and high temperatures. The second is:

$$\Omega_D = \frac{A}{T^{\circ B}} + \frac{C}{\exp(DT^{\circ})} + \frac{E}{\exp(FT^{\circ})} + \frac{G}{\exp(HT^{\circ})} \quad (5-213b)$$

**TABLE 5-11 Estimates for  $\epsilon_i$  and  $\sigma_i$  (K, Å, atm, cm<sup>3</sup>, mol)**

|                      |   |   |
|----------------------|---|---|
| Critical point       | $\epsilon/k = 0.75 T_c$                     | $\sigma = 0.841 V_c^{1/3}$ or $2.44 (T_c/P_c)^{1/3}$                  |
| Critical point       | $\epsilon/k = 65.3 T_c \rho_c^{-3.6}$       | $\sigma = \frac{1.866 V_c^{1/3}}{\rho_c^{1.2}}$                       |
| Normal boiling point | $\epsilon/k = 1.15 T_b$                     | $\sigma = 1.18 V_b^{1/3}$   |
| Melting point        | $\epsilon/k = 1.92 T_m$                     | $\sigma = 1.222 V_m^{1/3}$  |
| Acentric factor      | $\epsilon/k = (0.7915 + 0.1693 \omega) T_c$ | $\sigma = (2.3551 - 0.087 \omega) \left(\frac{T_c}{P_c}\right)^{1/3}$ |

NOTE: These values may not agree closely, so usage of a consistent basis is suggested (e.g., data at the normal boiling point).

**TABLE 5-12 Atomic Diffusion Volumes for Use in Estimating  $D_{AB}$  by the Method of Fuller, Schettler, and Giddings [10]**

| Atomic and Structural Diffusion-Volume Increments, $v_i$ (cm <sup>3</sup> /mol) |      |                                    |       |
|---|------|------------------------------------|-------|
| C   | 16.5 | (Cl)                               | 19.5  |

| O   | 5.48 | Aromatic ring                      | -20.2 |
| (N)   | 5.69 | Heterocyclic ring                  | -20.2 |
| Diffusion Volumes for Simple Molecules, $\Sigma v_i$ (cm <sup>3</sup> /mol)     |      |                                    |       |
| H <sub>2</sub>  | 7.07 | CO                                 | 18.9  |
| D <sub>2</sub>  | 6.70 | CO <sub>2</sub>                    | 26.9  |
| He  | 2.88 | N <sub>2</sub> O                   | 35.9  |
| N <sub>2</sub>  | 17.9 | NH <sub>3</sub>                    | 14.9  |
| O <sub>2</sub>  | 16.6 | H <sub>2</sub> O                   | 12.7  |
| Air   | 20.1 | (CCl <sub>2</sub> F <sub>2</sub> ) | 114.8 |
| Ar  | 16.1 | (SF <sub>6</sub> )                 | 69.7  |
| Kr  | 22.8 | (Cl <sub>2</sub> )                 | 37.7  |
| (Xe)  | 37.9 | (Br <sub>2</sub> )                 | 67.2  |
| Ne  | 5.59 | (SO <sub>2</sub> )                 | 41.1  |

Parentheses indicate that the value listed is based on only a few data points.

where  $A = 1.06036$ ,  $B = 0.15610$ ,  $C = 0.1930$ ,  $D = 0.47635$ ,  $E = 1.03587$ ,  $F = 1.52996$ ,  $G = 1.76474$ , and  $H = 3.89411$ .

**Fuller, Schettler, and Giddings [10]** The parameters and constants for this correlation were determined by regression analysis of 340 experimental diffusion coefficient values of 153 binary systems. Values of  $\Sigma v_i$  used in this equation are in Table 5-12.

**Binary Mixtures—Low Pressure—Polar Components** The Brokaw [4] correlation was based on the Chapman-Enskog equation, but  $\sigma_{AB}^*$  and  $\Omega_D^*$  were evaluated with a modified Stockmayer potential for polar molecules. Hence, slightly different symbols are used. That potential model reduces to the Lennard-Jones 6-12 potential for interactions between nonpolar molecules. As a result, the method should yield accurate predictions for polar as well as nonpolar gas mixtures. Brokaw presented data for 9 relatively polar pairs along with the prediction. The agreement was good: an average absolute error of 6.4 percent, considering the complexity of some of the gas pairs [e.g., (CH<sub>3</sub>)<sub>2</sub>O and CH<sub>3</sub>Cl]. Despite that, Poling, (op. cit.) found the average error was 9.0 percent for combinations of mixtures (including several polar-nonpolar gas pairs), temperatures and pressures. In this equation,  $\Omega_D$  is calculated as described previously, and other terms are:

$$\begin{aligned} \Omega_{D^*} &= \Omega_D + 0.19 \delta_{AB}^2 / T^\circ & T^\circ &= kT / \epsilon_{AB} \\ \sigma_{AB}^* &= (\sigma_A \sigma_B)^{1/2} & \sigma_i^* &= [1.585 V_{bi} / (1 + 1.3 \delta_i^2)]^{1/3} \\ \delta_{AB} &= (\delta_A \delta_B)^{1/2} & \delta_i &= 1.94 \times 10^3 \mu_i^2 / V_{bi} T_{bi} \\ \epsilon_{AB} &= (\epsilon_A \epsilon_B)^{1/2} & \epsilon_i / k &= 1.18 (1 + 1.3 \delta_i^2) T_{bi} \end{aligned}$$

**Binary Mixtures—High Pressure** Of the various categories of gas-phase diffusion, this is the least studied. This is so because of the effects of diffusion being easily distorted by even a slight pressure gradient, which is difficult to avoid at high pressure. Harstad and Bellan [Ind. Eng. Chem. Res. 43, 645 (2004)] developed a corresponding-states expression that extends the Chapman-Enskog method, covered earlier. They express the diffusivity at high pressure by accounting for the reduced temperature, and they suggest employing an equation of state and shifting from  $D_{AB}^o = f(T, P)$  to  $D_{AB} = g(T, V)$ .

**Self-Diffusivity** Self-diffusivity is a property that has little intrinsic value, e.g., for solving separation problems. Despite that, it reveals quite a lot about the inherent nature of molecular transport, because the effects of discrepancies of other physical properties are eliminated, except for those that constitute isotopic differences, which are necessary to ascertain composition differences. Self-diffusivity has been studied extensively under high pressures, e.g., greater than 70 atm. There are few accurate estimation methods for mutual diffusivities at such high pressures, because composition measurements are difficult.

The general observation for gas-phase diffusion  $D_{AB} P = \text{constant}$ , which holds at low pressure, is not valid at high pressure. Rather,  $D_{AB} P$  decreases as pressure increases. In addition, composition effects, which frequently are negligible at low pressure, are very significant at high pressure.

Liu and Ruckenstein [Ind. Eng. Chem. Res. 36, 3937 (1997)] studied self-diffusion for both liquids and gases. They proposed a semiempirical equation, based on hard-sphere theory, to estimate self-diffusivities. They extended it to Lennard-Jones fluids. The necessary energy parameter is estimated from viscosity data, but the molecular collision diameter is estimated from diffusion data. They compared their estimates to 26 pairs, with a total of 1822 data points, and achieved a relative deviation of 7.3 percent.

Zielinski and Hanley [AIChE J. 45, 1 (1999)] developed a model to predict multicomponent diffusivities from self-diffusion coefficients and thermodynamic information. Their model was tested by estimated experimental diffusivity values for ternary systems, predicting drying behavior of ternary systems, and reconciling ternary self-diffusion data measured by pulsed-field gradient NMR.

Mathur and Thodos [18] showed that for reduced densities less than unity, the product  $D_{AB} \rho$  is approximately constant at a given temperature. Thus, by knowing the value of the product at low pressure, it is possible to estimate its value at a higher pressure. They found at higher pressures the density increases, but the product  $D_{AB} \rho$  decreases rapidly. In their correlation,  $\beta = M_A^{1/2} P_C^{1/3} / T_C^{5/6}$ .

Lee and Thodos [14] presented a generalized treatment of self-diffusivity for gases (and liquids). These correlations have been tested for more than 500 data points each. The average deviation of the first is 0.51 percent, and that of the second is 17.2 percent.  $\delta = M_A^{1/2} / P_C^{1/2} V_C^{5/6}$ ,  $s/\text{cm}^2$ , and where  $G = (X^\circ - X) / (X^\circ - 1)$ ,  $X = \rho_r / T_r^{0.1}$ , and  $X^\circ = \rho_r / T_r^{0.1}$  evaluated at the solid melting point.

Lee and Thodos [15] expanded their earlier treatment of self-diffusivity to cover 58 substances and 975 data points, with an average absolute deviation of 5.26 percent. Their correlation is too involved to repeat here, but those interested should refer to the original paper.

Liu, Silva, and Macedo [Chem. Eng. Sci. 53, 2403 (1998)] present a theoretical approach incorporating hard-sphere, square-well, and Lennard-Jones models. They compared their resulting estimates to estimates generated via the Lee-Thodos equation. For 2047 data points with nonpolar species, the Lee-Thodos equation was slightly superior to the Lennard-Jones fluid-based model, that is, 5.2 percent average deviation versus 5.5 percent, and much better than the square-well fluid-based model (10.6 percent deviation). For over 467 data points with polar species, the Lee-Thodos equation yielded 36 percent average deviation, compared with 25 percent for the Lennard-Jones fluid-based model, and 19 percent for the square-well fluid-based model.

Silva, Liu, and Macedo [Chem. Eng. Sci. 53, 2423 (1998)] present an improved theoretical approach incorporating slightly different Lennard-Jones models. For 2047 data points with nonpolar species, their best model yielded 4.5 percent average deviation, while the Lee-Thodos equation yielded 5.2 percent, and the prior Lennard-Jones fluid-based model produced 5.5 percent. The new model was much better than all the other models for over 424 data points with polar species, yielding 4.3 percent deviation, while the Lee-Thodos equation yielded 34 percent and the Lennard-Jones fluid-based model yielded 23 percent.

**Supercritical Mixtures** DeBenedetti and Reid [AIChE J., 32, 2034 (1986) and 33, 496 (1987)] showed that conventional correlations based on the Stokes-Einstein relation (for liquid phase) tend to overpredict diffusivities in the supercritical state. Nevertheless, they observed that the Stokes-Einstein group  $D_{AB} \mu / T$  was constant. Thus, although no general correlation applies, only one data point is necessary to examine variations of fluid viscosity and/or temperature effects. They explored certain combinations of aromatic solids in SF<sub>6</sub> and CO<sub>2</sub>.

Sun and Chen [25] examined tracer diffusion data of aromatic solutes in alcohols up to the supercritical range and found their data correlated with average deviations of 5 percent and a maximum deviation of 17 percent for their rather limited set of data.

Catchpole and King [6] examined binary diffusion data of near-critical fluids in the reduced density range of 1 to 2.5 and found that their data correlated with average deviations of 10 percent and a maximum deviation of 60 percent. They observed two classes of behavior. For the first, no correction factor was required ( $R = 1$ ). That class was comprised of alcohols as solvents with aromatic or aliphatic solutes, or

carbon dioxide as a solvent with aliphatics except ketones as solutes, or ethylene as a solvent with aliphatics except ketones and naphthalene as solutes. For the second class, the correction factor was  $R = X^{0.17}$ . The class was comprised of carbon dioxide with aromatics; ketones and carbon tetrachloride as solutes; and aliphatics (propane, hexane, dimethyl butane), sulfur hexafluoride, and chlorotrifluoromethane as solvents with aromatics as solutes. In addition, sulfur hexafluoride combined with carbon tetrachloride, and chlorotrifluoromethane combined with 2-propanone were included in that class. In all cases,  $X = (1 + (V_{CA}/V_{CB})^{1/3})^2 / (1 + M_A/M_B)$  was in the range of 1 to 10.

Liu and Ruckenstein [17] presented a semiempirical equation to estimate diffusivities under supercritical conditions that is based on the Stokes-Einstein relation and the long-range correlation, respectively. The parameter  $2\theta_{AB}^*$  was estimated from the Peng-Robinson equation of state. In addition,  $f = 2.72 - 0.3445 T_{CB}/T_{CA}$  for most solutes, but for  $C_5$  through  $C_{14}$  linear alkanes,  $f = 3.046 - 0.786 T_{CB}/T_{CA}$ . In both cases  $T_{ci}$  is the species critical temperature. They compared their estimates to 33 pairs, with a total of 598 data points, and achieved lower deviations (5.7 percent) than the Sun-Chen correlation (13.3 percent) and the Catchpole-King equation (11.0 percent).

He and Yu [13] presented a semiempirical equation to estimate diffusivities under supercritical conditions that is based on hard-sphere theory. It is limited to  $\rho_r \geq 0.21$ , where the reduced density is  $\rho_r = \rho_A(T, P)/\rho_{CA}$ . They compared their estimates to 107 pairs, with a total of 1167 data points, and achieved lower deviations (7.8 percent) than the Catchpole-King equation (9.7 percent), which was restricted to  $\rho_r \geq 1$ .

Silva and Macedo [Ind. Eng. Chem. Res. 37, 1490 (1998)] measured diffusivities of ethers in  $CO_2$  under supercritical conditions and compared them to the Wilke-Chang [Eq. (5-218)], Tyn-Calus [Eq. (5-219)], Catchpole-King [Eq. (5-210)], and their own equations. They found that the Wilke-Chang equation provided the best fit.

Gonzalez, Bueno, and Medina [Ind. Eng. Chem. Res. 40, 3711 (2001)] measured diffusivities of aromatic compounds in  $CO_2$  under supercritical conditions and compared them to the Wilke-Chang [Eq. (5-218)], Hayduk-Minhas [Eq. (5-226)], and other equations. They recommended the Wilke-Chang equation (which yielded a relative error of 10.1 percent) but noted that the He-Yu equation provided the best fit (5.5 percent).

**Low-Pressure/Multicomponent Mixtures** These methods are outlined in Table 5-13. Stefan-Maxwell equations were discussed earlier. Smith and Taylor [23] compared various methods for predicting multicomponent diffusion rates and found that Eq. (5-214) was superior among the effective diffusivity approaches, though none is very good. They also found that linearized and exact solutions are roughly equivalent and accurate.

Blanc [3] provided a simple limiting case for dilute component  $i$  diffusing in a stagnant medium (i.e.,  $N \approx 0$ ), and the result, Eq. (5-215), is known as Blanc's law. The restriction basically means that the compositions of all the components, besides component  $i$ , are relatively large and uniform.

Wilke [29] obtained solutions to the Stefan-Maxwell equations. The first, Eq. (5-216), is simple and reliable under the same conditions as Blanc's law. This equation applies when component  $i$  diffuses through

a stagnant mixture. It has been tested and verified for diffusion of toluene in hydrogen + air + argon mixtures and for diffusion of ethyl propionate in hydrogen + air mixtures [Fairbanks and Wilke *Ind. Eng. Chem.*, 42, 471 (1950)]. When the compositions vary from one boundary to the other, Wilke recommends that the arithmetic average mole fractions be used. Wilke also suggested using the Stefan-Maxwell equation, which applies when the fluxes of two or more components are significant. In this situation, the mole fractions are arithmetic averages of the boundary conditions, and the solution requires iteration because the ratio of fluxes is not known a priori.

## DIFFUSIVITY ESTIMATION—LIQUIDS

Many more correlations are available for diffusion coefficients in the liquid phase than for the gas phase. Most, however, are restricted to binary diffusion at infinite dilution  $D_{AB}^0$  or to self-diffusivity  $D_{AA}$ . This reflects the much greater complexity of liquids on a molecular level. For example, gas-phase diffusion exhibits negligible composition effects and deviations from thermodynamic ideality. Conversely, liquid-phase diffusion almost always involves volumetric and thermodynamic effects due to composition variations. For concentrations greater than a few mole percent of  $A$  and  $B$ , corrections are needed to obtain the true diffusivity. Furthermore, there are many conditions that do not fit any of the correlations presented here. Thus, careful consideration is needed to produce a reasonable estimate. Again, if diffusivity data are available at the conditions of interest, then they are strongly preferred over the predictions of any correlations. Experimental values for liquid mixtures are listed in Table 2-325.

**Stokes-Einstein and Free-Volume Theories** The starting point for many correlations is the Stokes-Einstein equation. This equation is derived from continuum fluid mechanics and classical thermodynamics for the motion of large spherical particles in a liquid. For this case, the need for a molecular theory is cleverly avoided. The Stokes-Einstein equation is (Bird et al.)

$$D_{AB} = \frac{kT}{6\pi r_A \mu_B} \quad (5-217)$$

where  $A$  refers to the solute and  $B$  refers to the solvent. This equation is applicable to very large unhydrated molecules ( $M > 1000$ ) in low-molecular-weight solvents or where the molar volume of the solute is greater than  $500 \text{ cm}^3/\text{mol}$  (Reddy and Doraiswamy, *Ind. Eng. Chem. Fundam.*, 6, 77 (1967); Wilke and Chang [30]). Despite its intellectual appeal, this equation is seldom used "as is." Rather, the following principles have been identified: (1) The diffusion coefficient is inversely proportional to the size  $r_A \approx V_A^{1/3}$  of the solute molecules. Experimental observations, however, generally indicate that the exponent of the solute molar volume is larger than one-third. (2) The term  $D_{AB}\mu_B/T$  is approximately constant only over a 10-to-15 K interval. Thus, the dependence of liquid diffusivity on properties and conditions does not generally obey the interactions implied by that grouping. For example, Robinson, Edmister, and Dullien [*Ind. Eng. Chem. Fundam.*, 5, 75 (1966)] found that  $\ln D_{AB} \propto -1/T$ . (3) Finally, pressure does not affect liquid-phase diffusivity much, since  $\mu_B$  and  $V_A$  are only weakly pressure-dependent. Pressure does have an impact at very high levels.

**TABLE 5-13 Relationships for Diffusivities of Multicomponent Gas Mixtures at Low Pressure**

| Authors*                              | Equation  |
|---------------------------------------|---|
| Stefan-Maxwell, Smith and Taylor [23] | $D_{im} = \left[ 1 - x_i \left( \sum_{j=1}^{NC} N_j \right) / N_i \right] \sum_{j=1}^{NC} \left[ \left( x_j - \frac{x_i N_i}{N_i} \right) / D_{ij} \right] \quad (5-214)$ |
| Blanc [2]                             | $D_{im} = \left( \sum_{j=1}^{NC} \frac{x_j}{D_{ij}} \right)^{-1} \quad (5-215)$   |
| Wilke [29]                            | $D_{im} = \left( \sum_{j=1, j \neq i}^{NC} \frac{x_j}{D_{ij}} \right)^{-1} \quad (5-216)$   |

\*References are listed at the beginning of the "Mass Transfer" subsection.

Another advance in the concepts of liquid-phase diffusion was provided by Hildebrand [*Science*, **174**, 490 (1971)] who adapted a theory of viscosity to self-diffusivity. He postulated that  $D_{A'A}^{\circ} = B(V - V_{ms})/V_{ms}$ , where  $D_{A'A}^{\circ}$  is the self-diffusion coefficient,  $V$  is the molar volume, and  $V_{ms}$  is the molar volume at which fluidity is zero (i.e., the molar volume of the solid phase at the melting temperature). The difference ( $V - V_{ms}$ ) can be thought of as the free volume, which increases with temperature; and  $B$  is a proportionality constant.

Ertl and Dullien (ibid.) found that Hildebrand's equation could not fit their data with  $B$  as a constant. They modified it by applying an empirical exponent  $n$  (a constant greater than unity) to the volumetric ratio. The new equation is not generally useful, however, since there is no means for predicting  $n$ . The theory does identify the free volume as an important physical variable, since  $n > 1$  for most liquids implies that diffusion is more strongly dependent on free volume than is viscosity.

**Dilute Binary Nonelectrolytes: General Mixtures** These correlations are outlined in Table 5-14.

**Wilke-Chang [30]** This correlation for  $D_{AB}^{\circ}$  is one of the most widely used, and it is an empirical modification of the Stokes-Einstein equation. It is not very accurate, however, for water as the solute. Otherwise, it applies to diffusion of very dilute  $A$  in  $B$ . The average absolute error for 251 different systems is about 10 percent.  $\Phi_B$  is an association factor of solvent  $B$  that accounts for hydrogen bonding.

| Component $B$ | $\Phi_B$ |
|---------------|----------|
| Water         | 2.26     |
| Methanol      | 1.9      |
| Ethanol       | 1.5      |
| Propanol      | 1.2      |
| Others        | 1.0      |

The value of  $\Phi_B$  for water was originally stated as 2.6, although when the original data were reanalyzed, the empirical best fit was 2.26. Random comparisons of predictions with 2.26 versus 2.6 show no consistent advantage for either value, however. Kooijman [*Ind. Eng. Chem. Res.* **41**, 3326 (2002)] suggests replacing  $V_A$  with  $\theta_A V_{A^*}$ , in which  $\theta_A = 1$  except when  $A = \text{water}$ ,  $\theta_A = 4.5$ . This modification leads to an overall error of 8.7 percent for 41 cases he compared. He suggests retaining  $\Phi_B = 2.6$  when  $B = \text{water}$ . It has been suggested to replace the exponent of 0.6 with 0.7 and to use an association factor of 0.7 for systems containing aromatic hydrocarbons. These modifications, however, are not recommended by Umesi and Danner [27]. Lees and Sarram [*J. Chem. Eng. Data*, **16**, 41 (1971)] present a comparison of the association parameters. The average absolute error for 87 different solutes in water is 5.9 percent.

**Tyn-Calus [26]** This correlation requires data in the form of molar volumes and parachors  $\psi_i = V_i \sigma_i^{1/4}$  (a property which, over moderate temperature ranges, is nearly constant), measured at the same temperature (not necessarily the temperature of interest). The parachors for the components may also be evaluated at different temperatures from each other. Quale [*Chem. Rev.* **53**, 439 (1953)] has compiled values of  $\psi_i$  for many chemicals. Group contribution methods are available for estimation purposes (Poling et al.). The following suggestions were made by Poling et al.: The correlation is constrained to cases in which  $\mu_B < 30$  cP. If the solute is water or if the solute is an organic acid and the solvent is not water or a short-chain alcohol, dimerization of the solute  $A$  should be assumed for purposes of estimating its volume and parachor. For example, the appropriate values for water as solute at 25°C are  $V_W = 37.4$  cm<sup>3</sup>/mol and  $\psi_W = 105.2$  cm<sup>3</sup>g<sup>1/4</sup>/s<sup>1/2</sup>/mol. Finally, if the solute is nonpolar, the solvent volume and parachor should be multiplied by  $\delta\mu_B$ . According to Kooijman (ibid.), if the Brock-Bird method (described in Poling et al.) is used to

**TABLE 5-14 Correlations for Diffusivities of Dilute, Binary Mixtures of Nonelectrolytes in Liquids**

| Authors <sup>a</sup>              | Equation  | Error |
|-----------------------------------|---|-------|
| 1. General Mixtures               |   |       |
| Wilke-Chang [30]                  | $D_{AB}^{\circ} = \frac{7.4 \times 10^{-8} (\Phi_B M_B)^{1/2} T}{\mu_B V_A^{0.6}} \quad (5-218)$  | 20%   |
| Tyn-Calus [26]                    | $D_{AB}^{\circ} = \frac{8.93 \times 10^{-8} (V_A/V_B^2)^{1/6} (\psi_B/\psi_A)^{0.6} T}{\mu_B} \quad (5-219)$  | 10%   |
| Umesi-Danner [27]                 | $D_{AB}^{\circ} = \frac{2.75 \times 10^{-8} (R_B/R_A^{2/3}) T}{\mu_B} \quad (5-220)$  | 16%   |
| Siddiqi-Lucas [22]                | $D_{AB}^{\circ} = \frac{9.89 \times 10^{-8} V_B^{0.265} T}{V_A^{0.45} \mu_B^{0.907}} \quad (5-221)$   | 13%   |
| 2. Gases in Low Viscosity Liquids |   |       |
| Sridhar-Potter [24]               | $D_{AB}^{\circ} = D_{BB} \left( \frac{V_{cB}}{V_{cA}} \right)^{2/3} \left( \frac{V_B}{V_{mB}} \right) \quad (5-222)$  | 18%   |
| Chen-Chen [7]                     | $D_{AB}^{\circ} = 2.018 \times 10^{-9} \frac{(\beta V_{cB})^{2/3} (RT_{cB})^{1/2}}{M_A^{1/6} (M_B V_{cA})^{1/3}} (V_f - 1) \left( \frac{T}{T_{cA}} \right)^{1/2} \quad (5-223)$ | 6%    |
| 3. Aqueous Solutions              |   |       |
| Hayduk-Laudie [11]                | $D_{AW}^{\circ} = \frac{13.16 \times 10^{-5}}{\mu_w^{1.14} V_A^{0.589}} \quad (5-224)$  | 18%   |
| Siddiqi-Lucas [22]                | $D_{AW}^{\circ} = 2.98 \times 10^{-7} V_A^{-0.5473} \mu_w^{-1.026} T \quad (5-225)$   | 13%   |
| 4. Hydrocarbon Mixtures           |   |       |
| Hayduk-Minhas [12]                | $D_{AB}^{\circ} = 13.3 \times 10^{-8} T^{1.47} \mu_B^{(10.2/V_A - 0.791)} V_A^{-0.71} \quad (5-226)$  | 5%    |
| Matthews-Akgerman [19]            | $D_{AB}^{\circ} = 32.88 M_A^{-0.61} V_D^{-1.04} T^{0.5} (V_B - V_D) \quad (5-227)$  | 5%    |
| Riazi-Whitson [21]                | $D_{AB} = 1.07 \frac{(\rho D_{AB})^{\circ}}{\rho} \left( \frac{\mu}{\mu^{\circ}} \right)^{-0.27 - 0.38 \omega + (-0.05 + 0.1 \omega) P} \quad (5-228)$                          | 15%   |

<sup>a</sup>References are listed at the beginning of the "Mass Transfer" subsection.

estimate the surface tension, the error is only increased by about 2 percent, relative to employing experimentally measured values.

**Umesi-Danner [27]** They developed an equation for nonaqueous solvents with nonpolar and polar solutes. In all, 258 points were involved in the regression.  $R_i$  is the radius of gyration in Å of the component molecule, which has been tabulated by Passut and Danner [*Chem. Eng. Progress Symp. Ser.*, **140**, 30 (1974)] for 250 compounds. The average absolute deviation was 16 percent, compared with 26 percent for the Wilke-Chang equation.

**Siddiqi-Lucas [22]** In an impressive empirical study, these authors examined 1275 organic liquid mixtures. Their equation yielded an average absolute deviation of 13.1 percent, which was less than that for the Wilke-Chang equation (17.8 percent). Note that this correlation does not encompass aqueous solutions; those were examined and a separate correlation was proposed, which is discussed later.

**Binary Mixtures of Gases in Low-Viscosity, Nonelectrolyte Liquids** **Sridhar and Potter [24]** derived an equation for predicting gas diffusion through liquid by combining existing correlations. Hildebrand had postulated the following dependence of the diffusivity for a gas in a liquid:  $D_{AB}^0 = D_{B'B}(V_{cB}/V_{cA})^{2/3}$ , where  $D_{B'B}$  is the solvent self-diffusion coefficient and  $V_{cA}$  is the critical volume of component  $i$ , respectively. To correct for minor changes in volumetric expansion, Sridhar and Potter multiplied the resulting equation by  $V_B/V_{mB}$ , where  $V_{mB}$  is the molar volume of the liquid  $B$  at its melting point and  $D_{B'B}$  can be estimated by the equation of Ertl and Dullien (see p. 5-54). Sridhar and Potter compared experimentally measured diffusion coefficients for twenty-seven data points of eleven binary mixtures. Their average absolute error was 13.5 percent, but Chen and Chen [7] analyzed about 50 combinations of conditions and 3 to 4 replicates each and found an average error of 18 percent. This correlation does not apply to hydrogen and helium as solutes. However, it demonstrates the usefulness of self-diffusion as a means to assess mutual diffusivities and the value of observable physical property changes, such as molar expansion, to account for changes in conditions.

**Chen-Chen [7]** Their correlation was based on diffusion measurements of 50 combinations of conditions with 3 to 4 replicates each and exhibited an average error of 6 percent. In this correlation,  $V_r = V_B/[0.9724(V_{mB} + 0.04765)]$  and  $V_{mB}$  is the liquid molar volume at the melting point, as discussed previously. Their association parameter  $\beta$  [which is different from the definition of that symbol in Eq. (5-229)] accounts for hydrogen bonding of the solvent. Values for acetonitrile and methanol are:  $\beta = 1.58$  and  $2.31$ , respectively.

**Dilute Binary Mixtures of a Nonelectrolyte in Water** The correlations that were suggested previously for general mixtures, unless specified otherwise, may also be applied to diffusion of miscellaneous solutes in water. The following correlations are restricted to the present case, however.

**Hayduk and Laudie [11]** They presented a simple correlation for the infinite dilution diffusion coefficients of nonelectrolytes in water. It has about the same accuracy as the Wilke-Chang equation (about 5.9 percent). There is no explicit temperature dependence, but the 1.14 exponent on  $\mu_w$  compensates for the absence of  $T$  in the numerator. That exponent was misprinted (as 1.4) in the original article and has been reproduced elsewhere erroneously.

**Siddiqi and Lucas [227]** These authors examined 658 aqueous liquid mixtures in an empirical study. They found an average absolute deviation of 19.7 percent. In contrast, the Wilke-Chang equation gave 35.0 percent and the Hayduk-Laudie correlation gave 30.4 percent.

**Dilute Binary Hydrocarbon Mixtures** **Hayduk and Minhas [12]** presented an accurate correlation for normal paraffin mixtures that was developed from 58 data points consisting of solutes from  $C_5$  to  $C_{32}$  and solvents from  $C_5$  to  $C_{16}$ . The average error was 3.4 percent for the 58 mixtures.

**Matthews and Akgerman [19]** The free-volume approach of Hildebrand was shown to be valid for binary, dilute liquid paraffin mixtures (as well as self-diffusion), consisting of solutes from  $C_5$  to  $C_{16}$  and solvents of  $C_6$  and  $C_{12}$ . The term they referred to as the "diffusion volume" was simply correlated with the critical volume, as  $V_D = 0.308 V_c$ . We can infer from Table 5-11 that this is approximately related to the volume at the melting point as  $V_D = 0.945 V_m$ . Their correlation was valid for diffusion of linear alkanes at temperatures

up to 300°C and pressures up to 3.45 MPa. Matthews, Rodden, and Akgerman [*J. Chem. Eng. Data*, **32**, 317 (1987)] and Erkey and Akgerman [*AIChE J.*, **35**, 443 (1989)] completed similar studies of diffusion of alkanes, restricted to  $n$ -hexadecane and  $n$ -octane, respectively, as the solvents.

**Riasi and Whitson [21]** They presented a generalized correlation in terms of viscosity and molar density that was applicable to both gases and liquids. The average absolute deviation for gases was only about 8 percent, while for liquids it was 15 percent. Their expression relies on the Chapman-Enskog correlation [Eq. (5-202)] for the low-pressure diffusivity and the Stiel-Thodos [*AIChE J.*, **7**, 234 (1961)] correlation for low-pressure viscosity:

$$\mu^0 = \frac{x_A \mu_A^0 M_A^{1/2} + x_B \mu_B^0 M_B^{1/2}}{x_A M_A^{1/2} + x_B M_B^{1/2}}$$

where  $\mu_i^0 \xi_i = 3.4 \times 10^{-4} T_{r,i}^{0.94}$  for  $T_{r,i} < 1.5$  or  $\mu_i^0 \xi_i = 1.778 \times 10^{-4} (4.58 T_{r,i} - 1.67)^{0.58}$  for  $T_{r,i} > 1.5$ . In these equations,  $\xi_i = T_{c,i}^{1/6} P_{c,i}^{2/3} M_i^{1/2}$ , and units are in cP, atm, K, and mol. For dense gases or liquids, the Chung et al. [*Ind. Eng. Chem. Res.*, **27**, 671 (1988)] or Jossi-Stiel-Thodos [*AIChE J.*, **8**, 59 (1962)] correlation may be used to estimate viscosity. The latter is:

$$(\mu - \mu^0) \xi + 10^{-4} = (0.1023 + 0.023364 \rho_r + 0.058533 \rho_r^2 - 0.040758 \rho_r^3 + 0.093324 \rho_r^4)$$

$$\text{where } \xi = \frac{(x_A T_{cA} + x_B T_{cB})^{1/6}}{(x_A M_A + x_B M_B)^{1/2} (x_A P_{cA} + x_B P_{cB})}$$

$$\text{and } \rho_r = (x_A V_{cA} + x_B V_{cB}) \rho.$$

**Dilute Binary Mixtures of Nonelectrolytes with Water as the Solute** **Olander [AIChE J., **7**, 175 (1961)] modified the Wilke-Chang equation to adapt it to the infinite dilution diffusivity of water as the solute. The modification he recommended is simply the division of the right-hand side of the Wilke-Chang equation by 2.3. Unfortunately, neither the Wilke-Chang equation nor that equation divided by 2.3 fit the data very well. A reasonably valid generalization is that the Wilke-Chang equation is accurate if water is very insoluble in the solvent, such as pure hydrocarbons, halogenated hydrocarbons, and nitro-hydrocarbons. On the other hand, the Wilke-Chang equation divided by 2.3 is accurate for solvents in which water is very soluble, as well as those that have low viscosities. Such solvents include alcohols, ketones, carboxylic acids, and aldehydes. Neither equation is accurate for higher-viscosity liquids, especially diols.**

**Dilute Dispersions of Macromolecules in Nonelectrolytes** The Stokes-Einstein equation has already been presented. It was noted that its validity was restricted to large solutes, such as spherical macromolecules and particles in a continuum solvent. The equation has also been found to predict accurately the diffusion coefficient of spherical latex particles and globular proteins. Corrections to Stokes-Einstein for molecules approximating spheroids is given by Tanford *Physical Chemistry of Macromolecules*, Wiley, New York, (1961). Since solute-solute interactions are ignored in this theory, it applies in the dilute range only.

**Hiss and Cussler [AIChE J., **19**, 698 (1973)] Their basis is the diffusion of a small solute in a fairly viscous solvent of relatively large molecules, which is the opposite of the Stokes-Einstein assumptions. The large solvent molecules investigated were not polymers or gels but were of moderate molecular weight so that the macroscopic and microscopic viscosities were the same. The major conclusion is that  $D_{AB}^0 \mu^{2/3} = \text{constant}$  at a given temperature and for a solvent viscosity from  $5 \times 10^{-3}$  to 5 Pa·s or greater ( $5$  to  $5 \times 10^3$  cP). This observation is useful if  $D_{AB}^0$  is known in a given high-viscosity liquid (oils, tars, etc.). Use of the usual relation of  $D_{AB}^0 \propto 1/\mu$  for such an estimate could lead to large errors.**

**Concentrated, Binary Mixtures of Nonelectrolytes** Several correlations that predict the composition dependence of  $D_{AB}$  are summarized in Table 5-15. Most are based on known values of  $D_{AB}^0$  and  $D_{BA}^0$ . In fact, a rule of thumb states that, for many binary systems,  $D_{AB}^0$  and  $D_{BA}^0$  bound the  $D_{AB}$  vs.  $x_A$  curve. Cullinan's [8] equation predicts diffusivities even in lieu of values at infinite dilution, but requires accurate density, viscosity, and activity coefficient data.

**TABLE 5-15 Correlations of Diffusivities for Concentrated, Binary Mixtures of Nonelectrolyte Liquids**

| Authors*                 | Equation  |
|--------------------------|---|
| Caldwell-Babb [5]        | $D_{AB} = (x_A D_{BA}^{\circ} + x_B D_{AB}^{\circ}) \beta_A$ (5-231)  |
| Rathbun-Babb [20]        | $D_{AB} = (x_A D_{BA}^{\circ} + x_B D_{AB}^{\circ}) \beta_A^n$ (5-232)  |
| Vignes [28]              | $D_{AB} = D_{AB}^{\circ} D_{BA}^{\circ} \beta_A$ (5-233)  |
| Leffler-Cullinan [16]    | $D_{AB} \mu_{mix} = (D_{AB}^{\circ} \mu_B)^{x_B} (D_{BA}^{\circ} \mu_A)^{x_A} \beta_A$ (5-234)  |
| Cussler [9]              | $D_{AB} = D_0 \left[ 1 + \frac{K}{x_A x_B} \left( \frac{\partial \ln x_A}{\partial \ln a_A} - 1 \right) \right]^{-1/2}$ (5-235)           |
| Cullinan [8]             | $D_{AB} = \frac{kT}{2\pi \mu_{mix} (V/A)^{1/3}} \left[ \frac{2\pi x_A x_B \beta_A}{1 + \beta_A (2\pi x_A x_B - 1)} \right]^{1/2}$ (5-236) |
| Asfour-Dullien [1]       | $D_{AB} = \left( \frac{D_{AB}^{\circ}}{\mu_B} \right)^{x_B} \left( \frac{D_{BA}^{\circ}}{\mu_A} \right)^{x_A} \zeta \mu \beta_A$ (5-237)  |
| Siddiqi-Lucas [22]       | $D_{AB} = (C_B \bar{V}_B D_{AB}^{\circ} + C_A \bar{V}_A D_{BA}^{\circ}) \beta_A$ (5-238)  |
| Bosse and Bart no. 1 [3] | $D_{AB} = (D_{AB}^{\circ})^{x_B} (D_{BA}^{\circ})^{x_A} \exp \left( -\frac{g^E}{RT} \right)$ (5-239)                                      |
| Bosse and Bart no. 2 [3] | $\mu D_{AB} = (\mu_B D_{AB}^{\circ})^{x_B} (\mu_A D_{BA}^{\circ})^{x_A} \exp \left( -\frac{g^E}{RT} \right)$ (5-240)                      |

Relative errors for the correlations in this table are very dependent on the components of interest and are cited in the text. \*See the beginning of the "Mass Transfer" subsection for references.

Since the infinite dilution values  $D_{AB}^{\circ}$  and  $D_{BA}^{\circ}$  are generally unequal, even a thermodynamically ideal solution like  $\gamma_A = \gamma_B = 1$  will exhibit concentration dependence of the diffusivity. In addition, non-ideal solutions require a thermodynamic correction factor to retain the true "driving force" for molecular diffusion, or the gradient of the chemical potential rather than the composition gradient. That correction factor is:

$$\beta_A = 1 + \frac{\partial \ln \gamma_A}{\partial \ln x_A} \quad (5-229)$$

**Caldwell and Babb [5]** Darken [*Trans. Am. Inst. Mining Met. Eng.*, **175**, 184 (1948)] observed that solid-state diffusion in metallurgical applications followed a simple relation. His equation related the tracer diffusivities and mole fractions to the mutual diffusivity:

$$D_{AB} = (x_A D_B + x_B D_A) \beta_A \quad (5-230)$$

Caldwell and Babb used virtually the same equation to evaluate the mutual diffusivity for concentrated mixtures of common liquids.

Van Geet and Adamson [*J. Phys. Chem.*, **68**, 238 (1964)] tested that equation for the *n*-dodecane (*A*) and *n*-octane (*B*) system and found the average deviation of  $D_{AB}$  from experimental values to be -0.68 percent. In addition, that equation was tested for benzene + bromobenzene, *n*-hexane + *n*-dodecane, benzene +  $\text{CCl}_4$ , octane + decane, heptane + cetane, benzene + diphenyl, and benzene + nitromethane with success. For systems that depart significantly from thermodynamic ideality, it breaks down, sometimes by a factor of eight. For example, in the binary systems acetone +  $\text{CCl}_4$ , acetone + chloroform, and ethanol +  $\text{CCl}_4$ , it is not accurate. Thus, it can be expected to be fairly accurate for nonpolar hydrocarbons of similar molecular weight but not for polar-polar mixtures. Siddiqi, Krahn, and Lucas [*J. Chem. Eng. Data*, **32**, 48 (1987)] found that this relation was superior to those of Vignes and Leffler and Cullinan for a variety of mixtures. Umesi and Danner [27] found an average absolute deviation of 13.9 percent for 198 data points.

**Rathbun and Babb [20]** suggested that Darken's equation could be improved by raising the thermodynamic correction factor  $\beta_A$  to a power, *n*, less than unity. They looked at systems exhibiting negative deviations from Raoult's law and found  $n = 0.3$ . Furthermore, for polar-nonpolar mixtures, they found  $n = 0.6$ . In a separate study, Siddiqi and Lucas [22] followed those suggestions and found an average absolute error of 3.3 percent for nonpolar-nonpolar mixtures, 11.0 percent for polar-nonpolar mixtures, and 14.6 percent for polar-polar mixtures. Siddiqi, Krahn, and Lucas (ibid.) examined a few other mixtures and

found that  $n = 1$  was probably best. Thus, this approach is, at best, highly dependent on the type of components being considered.

Vignes [28] empirically correlated mixture diffusivity data for 12 binary mixtures. Later Ertl, Ghai, and Dollon [*AIChE J.*, **20**, 1 (1974)] evaluated 122 binary systems, which showed an average absolute deviation of only 7 percent. None of the latter systems, however, was very nonideal.

Leffler and Cullinan [16] modified Vignes' equation using some theoretical arguments to arrive at Eq. (5-234), which the authors compared to Eq. (5-233) for the 12 systems mentioned above. The average absolute maximum deviation was only 6 percent. Umesi and Danner [27], however, found an average absolute deviation of 11.4 percent for 198 data points. For normal paraffins, it is not very accurate. In general, the accuracies of Eqs. (5-233) and (5-234) are not much different, and since Vignes' is simpler to use, it is suggested. The application of either should be limited to nonassociating systems that do not deviate much from ideality ( $0.95 < \beta_A < 1.05$ ).

Cussler [9] studied diffusion in concentrated associating systems and has shown that, in associating systems, it is the size of diffusing clusters rather than diffusing solutes that controls diffusion.  $D_0$  is a reference diffusion coefficient discussed hereafter;  $a_A$  is the activity of component A; and  $K$  is a constant. By assuming that  $D_0$  could be predicted by Eq. (5-233) with  $\beta = 1$ ,  $K$  was found to be equal to 0.5 based on five binary systems and validated with a sixth binary mixture. The limitations of Eq. (5-235) using  $D_0$  and  $K$  defined previously have not been explored, so caution is warranted. Gurkan [*AIChE J.*, **33**, 175 (1987)] showed that  $K$  should actually be closer to 0.3 (rather than 0.5) and discussed the overall results.

Cullinan [8] presented an extension of Cussler's cluster diffusion theory. His method accurately accounts for composition and temperature dependence of diffusivity. It is novel in that it contains no adjustable constants, and it relates transport properties and solution thermodynamics. This equation has been tested for six very different mixtures by Rollins and Knaebel [*AIChE J.*, **37**, 470 (1991)], and it was found to agree remarkably well with data for most conditions, considering the absence of adjustable parameters. In the dilute region (of either A or B), there are systematic errors probably caused by the breakdown of certain implicit assumptions (that nevertheless appear to be generally valid at higher concentrations).

Asfour and Dullien [1] developed a relation for predicting alkane diffusivities at moderate concentrations that employs:

$$\zeta = \left( \frac{V_{fm}}{V_{fxA} V_{fxB}} \right)^{2/3} \frac{M_{xA} M_{xB}}{M_m} \quad (5-241)$$

where  $V_{f_i} = V_{\beta_i}^0$ ; the fluid free volume is  $V_{f_i} = V_i - V_{m_i}$  for  $i = A, B$ , and  $m$ , in which  $V_{m_i}$  is the molar volume of the liquid at the melting point and

$$V_{m,m} = \left( \frac{x_A^2}{V_{m_A}} + \frac{2x_A x_B}{V_{m_{AB}}} + \frac{x_B^2}{V_{m_B}} \right)^{-1}$$

and

$$V_{m_{AB}} = \left[ \frac{V_{m_A}^{1/3} + V_{m_B}^{1/3}}{2} \right]^3$$

and  $\mu$  is the mixture viscosity;  $M_m$  is the mixture mean molecular weight; and  $\beta_A$  is defined by Eq. (5-229). The average absolute error of this equation is 1.4 percent, while the Vignes equation and the Lefler-Cullinan equation give 3.3 percent and 6.2 percent, respectively.

*Siddiqi and Lucas* [22] suggested that component volume fractions might be used to correlate the effects of concentration dependence. They found an average absolute deviation of 4.5 percent for nonpolar-nonpolar mixtures, 16.5 percent for polar-nonpolar mixtures, and 10.8 percent for polar-polar mixtures.

*Bosse and Bart* added a term to account for excess Gibbs free energy, involved in the activation energy for diffusion, which was previously omitted. Doing so yielded minor modifications of the Vignes and Lefler-Cullinan equations [Eqs. (5-233) and (5-234), respectively]. The UNIFAC method was used to assess the excess Gibbs free energy. Comparing predictions of the new equations with data for 36 pairs and 326 data points yielded relative deviations of 7.8 percent and 8.9 percent, respectively, but which were better than the closely related Vignes (12.8 percent) and Lefler-Cullinan (10.4 percent) equations.

**Binary Electrolyte Mixtures** When electrolytes are added to a solvent, they dissociate to a certain degree. It would appear that the solution contains at least three components: solvent, anions, and cations. If the solution is to remain neutral in charge at each point (assuming the absence of any applied electric potential field), the anions and cations diffuse effectively as a single component, as for molecular diffusion. The diffusion of the anionic and cationic species in the solvent can thus be treated as a binary mixture.

**Nernst-Haskell** The theory of dilute diffusion of salts is well developed and has been experimentally verified. For dilute solutions of a single salt, the well-known Nernst-Haskell equation (Poling et al.) is applicable:

$$D_{AB}^0 = \frac{RT}{F^2} \frac{\left| \frac{1}{n_+} + \frac{1}{n_-} \right|}{\frac{1}{\lambda_+^0} + \frac{1}{\lambda_-^0}} = 8.9304 \times 10^{-10} T \frac{\left| \frac{1}{n_+} + \frac{1}{n_-} \right|}{\frac{1}{\lambda_+^0} + \frac{1}{\lambda_-^0}} \quad (5-242)$$

where  $D_{AB}^0$  = diffusivity based on molarity rather than normality of dilute salt A in solvent B,  $\text{cm}^2/\text{s}$ .

The previous definitions can be interpreted in terms of ionic-species diffusivities and conductivities. The latter are easily measured and depend on temperature and composition. For example, the equivalent conductance  $\Lambda$  is commonly tabulated in chemistry handbooks as the limiting (infinite dilution) conductance  $\Lambda_0$ , and at standard concentrations, typically at 25°C.  $\Lambda = 1000K/C = \lambda_+ + \lambda_- = \Lambda_0 + f(C)$ , ( $\text{cm}^2/\text{ohm gequiv}$ );  $K = \alpha/R$  = specific conductance, ( $\text{ohm cm}^{-1}$ );  $C$  = solution concentration, ( $\text{gequiv}/\ell$ );  $\alpha$  = conductance cell constant (measured), ( $\text{cm}^{-1}$ );  $R$  = solution electrical resistance, which is measured (ohm); and  $f(C)$  = a complicated function of concentration. The resulting equation of the electrolyte diffusivity is

$$D_{AB} = \frac{|\lambda_{\pm}| + |\lambda_{\pm}|}{(|\lambda_{\pm}|/D_+) + (|\lambda_{\pm}|/D_-)} \quad (5-243)$$

where  $|\lambda_{\pm}|$  represents the magnitude of the ionic charge and where the cationic or anionic diffusivities are  $D_{\pm} = 8.9304 \times 10^{-10} T \lambda_{\pm} / |\lambda_{\pm}| \text{ cm}^2/\text{s}$ . The coefficient is  $kN_0/F^2 = R/F^2$ . In practice, the equivalent conductance of the ion pair of interest would be obtained and supplemented with conductances of permutations of those ions and one independent cation and anion. This would allow determination of all the ionic conductances and hence the diffusivity of the electrolyte solution.

**Gordon** [J. Phys. Chem. **5**, 522 (1937)] Typically, as the concentration of a salt increases from infinite dilution, the diffusion coefficient

decreases rapidly from  $D_{AB}^0$ . As concentration is increased further, however,  $D_{AB}$  rises steadily, often becoming greater than  $D_{AB}^0$ . Gordon proposed the following empirical equation, which is applicable up to concentrations of  $2N$ :

$$D_{AB} = D_{AB}^0 \frac{1}{C_B \bar{V}_B} \frac{\mu_B}{\mu} \left( 1 + \frac{\ln \gamma_{\pm}}{\ln m} \right) \quad (5-244)$$

where  $D_{AB}^0$  is given by the Nernst-Haskell equation. References that tabulate  $\gamma_{\pm}$  as a function of  $m$ , as well as other equations for  $D_{AB}$ , are given by Poling et al.

**Morgan, Ferguson, and Scovazzo** [Ind. Eng. Chem. Res. **44**, 4815 (2005)] They studied diffusion of gases in ionic liquids having moderate to high viscosity (up to about 1000 cP) at 30°C. Their range was limited, and the empirical equation they found was

$$D_{AB} = 3.7 \times 10^{-3} \left( \frac{1}{\mu_B^{0.59} V_{A0} \rho_B^2} \right) \quad (5-245)$$

which yielded a correlation coefficient of 0.975. Of the estimated diffusivities 90 percent were within  $\pm 20$  percent of the experimental values. The exponent for viscosity approximately confirmed the observation of Hiss and Cussler (ibid).

**Multicomponent Mixtures** No simple, practical estimation methods have been developed for predicting multicomponent liquid-diffusion coefficients. Several theories have been developed, but the necessity for extensive activity data, pure component and mixture volumes, mixture viscosity data, and tracer and binary diffusion coefficients have significantly limited the utility of the theories (see Poling et al.).

The generalized Stefan-Maxwell equations using binary diffusion coefficients are not easily applicable to liquids since the coefficients are so dependent on conditions. That is, in liquids, each  $D_{ij}$  can be strongly composition dependent in binary mixtures and, moreover, the binary  $D_{ij}$  is strongly affected in a multicomponent mixture. Thus, the convenience of writing multicomponent flux equations in terms of binary coefficients is lost. Conversely, they apply to gas mixtures because each  $D_{ij}$  is practically independent of composition by itself and in a multicomponent mixture (see Taylor and Krishna for details).

One particular case of multicomponent diffusion that has been examined is the dilute diffusion of a solute in a homogeneous mixture (e.g., of A in B + C). Umesi and Danner [27] compared the three equations given below for 49 ternary systems. All three equations were equivalent, giving average absolute deviations of 25 percent.

**Perkins and Geankoplis** [Chem. Eng. Sci., **24**, 1035 (1969)]

$$D_{am} \mu_m^{0.8} = \sum_{\substack{j=1 \\ j \neq A}}^n x_j D_{Aj}^0 \mu_j^{0.8} \quad (5-246)$$

**Cullinan** [Can. J. Chem. Eng. **45**, 377 (1967)] This is an extension of Vignes' equation to multicomponent systems:

$$D_{am} = \prod_{\substack{j=1 \\ j \neq A}}^n (D_{Aj}^0)^{x_j} \quad (5-247)$$

**Lefler and Cullinan** [16] They extended their binary relation to an arbitrary multicomponent mixture, as follows:

$$D_{am} \mu_m = \prod_{\substack{j=1 \\ j \neq A}}^n (D_{Aj}^0 \mu_j)^{x_j} \quad (5-248)$$

where  $D_{Aj}$  is the dilute binary diffusion coefficient of A in j;  $D_{am}$  is the dilute diffusion of A through m;  $x_j$  is the mole fraction;  $\mu_j$  is the viscosity of component j; and  $\mu_m$  is the mixture viscosity.

**Akita** [Ind. Eng. Chem. Fundam., **10**, 89 (1981)] Another case of multicomponent dilute diffusion of significant practical interest is that of gases in aqueous electrolyte solutions. Many gas-absorption processes use electrolyte solutions. Akita presents experimentally tested equations for this case.

**Graham and Dranoff** [Ind. Eng. Chem. Fundam., **21**, 360 and 365 (1982)] They studied multicomponent diffusion of electrolytes in ion exchangers. They found that the Stefan-Maxwell interaction coefficients reduce to limiting ion tracer diffusivities of each ion.

**Pinto and Graham** [AIChE J. **32**, 291 (1986) and **33**, 436 (1987)] They studied multicomponent diffusion in electrolyte solutions. They focused on the Stefan-Maxwell equations and corrected for solvation effects. They achieved excellent results for 1-1 electrolytes in water at 25°C up to concentrations of 4M.

**Anderko and Lencka** [Ind. Eng. Chem. Res. **37**, 2878 (1998)] These authors present an analysis of self-diffusion in multicomponent aqueous electrolyte systems. Their model includes contributions of long-range (Coulombic) and short-range (hard-sphere) interactions. Their mixing rule was based on equations of nonequilibrium thermodynamics. The model accurately predicts self-diffusivities of ions and gases in aqueous solutions from dilute to about 30 mol/kg water. It makes it possible to take single-solute data and extend them to multicomponent mixtures.

**DIFFUSION OF FLUIDS IN POROUS SOLIDS**

Diffusion in porous solids is usually the most important factor controlling mass transfer in adsorption, ion exchange, drying, heterogeneous catalysis, leaching, and many other applications. Some of the applications of interest are outlined in Table 5-16. Applications of these equations are found in Secs. 16, 22, and 23.

Diffusion within the largest cavities of a porous medium is assumed to be similar to ordinary or bulk diffusion except that it is hindered by the pore walls (see Eq. 5-249). The tortuosity  $\tau$  that expresses this hindrance has been estimated from geometric arguments. Unfortunately,

measured values are often an order of magnitude greater than those estimates. Thus, the effective diffusivity  $D_{eff}$  (and hence  $\tau$ ) is normally determined by comparing a diffusion model to experimental measurements. The normal range of tortuosities for silica gel, alumina, and other porous solids is  $2 \leq \tau \leq 6$ , but for activated carbon,  $5 \leq \tau \leq 65$ .

In small pores and at low pressures, the mean free path  $\ell$  of the gas molecule (or atom) is significantly greater than the pore diameter  $d_{pore}$ . Its magnitude may be estimated from

$$\ell = \frac{3.2 \mu}{P} \left( \frac{RT}{2\pi M} \right)^{1/2} \text{ m}$$

As a result, collisions with the wall occur more frequently than with other molecules. This is referred to as the Knudsen mode of diffusion and is contrasted with ordinary or bulk diffusion, which occurs by intermolecular collisions. At intermediate pressures, both ordinary diffusion and Knudsen diffusion may be important [see Eqs. (5-252) and (5-253)].

For gases and vapors that adsorb on the porous solid, surface diffusion may be important, particularly at high surface coverage [see Eqs. (5-254) and (5-257)]. The mechanism of surface diffusion may be viewed as molecules hopping from one surface site to another. Thus, if adsorption is too strong, surface diffusion is impeded, while if adsorption is too weak, surface diffusion contributes insignificantly to the overall rate. Surface diffusion and bulk diffusion usually occur in parallel [see Eqs. (5-258) and (5-259)]. Although  $D_s$  is expected to be less than  $D_{eff}$ , the solute flux due to surface diffusion may be larger

**TABLE 5-16 Relations for Diffusion in Porous Solids**

| Mechanism                           | Equation   | Applies to   | References*          |
|-------------------------------------|--|--|----------------------|

|                                     | $D_{app} = D_{eff} + D_{s,eff} \rho_p \left( \frac{dq_i}{dp_i} \right)$ (5-260)  | " " " "  |                      |

\*See the beginning of the "Mass Transfer" subsection for references.

than that due to bulk diffusion if  $\partial q_i/\partial z \gg \partial C_i/\partial z$ . This can occur when a component is strongly adsorbed and the surface coverage is high. For all that, surface diffusion is not well understood. The references in Table 5-16 should be consulted for further details.

**INTERPHASE MASS TRANSFER**

Transfer of material between phases is important in most separation processes in which two phases are involved. When one phase is pure, mass transfer in the pure phase is not involved. For example, when a pure liquid is being evaporated into a gas, only the gas-phase mass transfer need be calculated. Occasionally, mass transfer in one of the two phases may be neglected even though pure components are not involved. This will be the case when the resistance to mass transfer is much larger in one phase than in the other. Understanding the nature and magnitudes of these resistances is one of the keys to performing reliable mass transfer. In this section, mass transfer between gas and liquid phases will be discussed. The principles are easily applied to the other phases.

**Mass-Transfer Principles: Dilute Systems** When material is transferred from one phase to another across an interface that separates the two, the resistance to mass transfer in each phase causes a concentration gradient in each, as shown in Fig. 5-26 for a gas-liquid interface. The concentrations of the diffusing material in the two phases immediately adjacent to the interface generally are unequal, even if expressed in the same units, but usually are assumed to be related to each other by the laws of thermodynamic equilibrium. Thus, it is assumed that the thermodynamic equilibrium is reached at the gas-liquid interface almost immediately when a gas and a liquid are brought into contact.

For systems in which the solute concentrations in the gas and liquid phases are dilute, the rate of transfer may be expressed by equations which predict that the rate of mass transfer is proportional to the difference between the bulk concentration and the concentration at the gas-liquid interface. Thus

$$N_A = k'_G(p - p_i) = k'_L(c_i - c) \tag{5-261}$$

where  $N_A$  = mass-transfer rate,  $k'_G$  = gas-phase mass-transfer coefficient,  $k'_L$  = liquid-phase mass-transfer coefficient,  $p$  = solute partial pressure in bulk gas,  $p_i$  = solute partial pressure at interface,  $c$  = solute concentration in bulk liquid, and  $c_i$  = solute concentration in liquid at interface.

The mass-transfer coefficients  $k'_G$  and  $k'_L$  by definition are equal to the ratios of the molar mass flux  $N_A$  to the concentration driving forces  $(p - p_i)$  and  $(c_i - c)$  respectively. An alternative expression for the rate of transfer in dilute systems is given by

$$N_A = k_C(y - y_i) = k_L(x_i - x) \tag{5-262}$$

where  $N_A$  = mass-transfer rate,  $k_C$  = gas-phase mass-transfer coefficient,  $k_L$  = liquid-phase mass-transfer coefficient,  $y$  = mole-fraction

solute in bulk-gas phase,  $y_i$  = mole-fraction solute in gas at interface,  $x$  = mole-fraction solute in bulk-liquid phase, and  $x_i$  = mole-fraction solute in liquid at interface.

The mass-transfer coefficients defined by Eqs. (5-261) and (5-262) are related to each other as follows:

$$k_C = k'_G p_T \tag{5-263}$$

$$k_L = k'_L \bar{\rho}_L \tag{5-264}$$

where  $p_T$  = total system pressure employed during the experimental determinations of  $k'_G$  values and  $\bar{\rho}_L$  = average molar density of the liquid phase. The coefficient  $k_C$  is relatively independent of the total system pressure and therefore is more convenient to use than  $k'_G$ , which is inversely proportional to the total system pressure.

The above equations may be used for finding the interfacial concentrations corresponding to any set of values of  $x$  and  $y$  provided the ratio of the individual coefficients is known. Thus

$$(y - y_i)/(x_i - x) = k_L/k_C = k'_L \bar{\rho}_L / k'_G p_T = L_M H_C / G_M H_L \tag{5-265}$$

where  $L_M$  = molar liquid mass velocity,  $G_M$  = molar gas mass velocity,  $H_L$  = height of one transfer unit based on liquid-phase resistance, and  $H_C$  = height of one transfer unit based on gas-phase resistance. The last term in Eq. (5-265) is derived from Eqs. (5-284) and (5-286).

Equation (5-265) may be solved graphically if a plot is made of the equilibrium vapor and liquid compositions and a point representing the bulk concentrations  $x$  and  $y$  is located on this diagram. A construction of this type is shown in Fig. 5-27, which represents a gas-absorption situation.

The interfacial mole fractions  $y_i$  and  $x_i$  can be determined by solving Eq. (5-265) simultaneously with the equilibrium relation  $y_i^\circ = F(x_i)$  to obtain  $y_i$  and  $x_i$ . The rate of transfer may then be calculated from Eq. (5-262).

If the equilibrium relation  $y_i^\circ = F(x_i)$  is sufficiently simple, e.g., if a plot of  $y_i^\circ$  versus  $x_i$  is a straight line, not necessarily through the origin, the rate of transfer is proportional to the difference between the bulk concentration in one phase and the concentration (in that same phase) which would be in equilibrium with the bulk concentration in the second phase. One such difference is  $y - y^\circ$ , and another is  $x^\circ - x$ . In this case, there is no need to solve for the interfacial compositions, as may be seen from the following derivation.

The rate of mass transfer may be defined by the equation

$$N_A = K_C(y - y^\circ) = k_C(y - y_i) = k_L(x_i - x) = K_L(x^\circ - x) \tag{5-266}$$

where  $K_C$  = overall gas-phase mass-transfer coefficient,  $K_L$  = overall liquid-phase mass-transfer coefficient,  $y^\circ$  = vapor composition in equilibrium with  $x$ , and  $x^\circ$  = liquid composition in equilibrium with vapor of composition  $y$ . This equation can be rearranged to the formula

$$\frac{1}{K_C} = \frac{1}{k_C} \left( \frac{y - y^\circ}{y - y_i} \right) = \frac{1}{k_C} + \frac{1}{k_C} \left( \frac{y_i - y^\circ}{y - y_i} \right) = \frac{1}{k_C} + \frac{1}{k_L} \left( \frac{y_i - y^\circ}{x_i - x} \right) \tag{5-267}$$

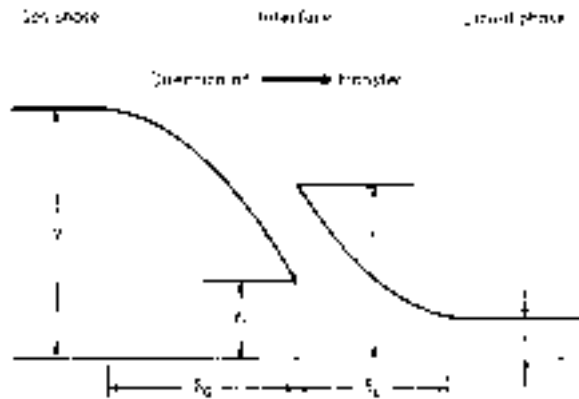

FIG. 5-26 Concentration gradients near a gas-liquid interface.

FIG. 5-27 Identification of concentrations at a point in a countercurrent absorption tower.

## 5-60 HEAT AND MASS TRANSFER

in view of Eq. (5-265). Comparison of the last term in parentheses with the diagram of Fig. 5-27 shows that it is equal to the slope of the chord connecting the points  $(x, y^\circ)$  and  $(x_i, y_i)$ . If the equilibrium curve is a straight line, then this term is the slope  $m$ . Thus

$$1/K_G = (1/k_G + m/k_L) \quad (5-268)$$

When Henry's law is valid ( $p_A = Hx_A$  or  $p_A = H'C_A$ ), the slope  $m$  can be computed according to the relationship

$$m = H/p_T = H'\bar{p}_L/p_T \quad (5-269)$$

where  $m$  is defined in terms of mole-fraction driving forces compatible with Eqs. (5-262) through (5-268), i.e., with the definitions of  $k_L$ ,  $k_G$ , and  $K_G$ .

If it is desired to calculate the rate of transfer from the overall concentration difference based on bulk-liquid compositions ( $x^\circ - x$ ), the appropriate overall coefficient  $K_L$  is related to the individual coefficients by the equation

$$1/K_L = [1/k_L + 1/(mk_G)] \quad (5-270)$$

Conversion of these equations to a  $k'_G, k'_L$  basis can be accomplished readily by direct substitution of Eqs. (5-263) and (5-264).

Occasionally one will find  $k'_L$  or  $K'_L$  values reported in units (SI) of meters per second. The correct units for these values are  $\text{kmol}/[(s \cdot \text{m}^2)(\text{kmol}/\text{m}^3)]$ , and Eq. (5-264) is the correct equation for converting them to a mole-fraction basis.

When  $k'_G$  and  $K'_G$  values are reported in units (SI) of  $\text{kmol}/[(s \cdot \text{m}^2)(\text{kPa})]$ , one must be careful in converting them to a mole-fraction basis to multiply by the total pressure actually employed in the original experiments and *not* by the total pressure of the system to be designed. This conversion is valid for systems in which Dalton's law of partial pressures ( $p = yp_T$ ) is valid.

Comparison of Eqs. (5-268) and (5-270) shows that for systems in which the equilibrium line is straight, the overall mass transfer coefficients are related to each other by the equation

$$K_L = mK_G \quad (5-271)$$

When the equilibrium curve is not straight, there is no strictly logical basis for the use of an overall transfer coefficient, since the value of  $m$  will be a function of position in the apparatus, as can be seen from Fig. 5-27. In such cases the rate of transfer must be calculated by solving for the interfacial compositions as described above.

Experimentally observed rates of mass transfer often are expressed in terms of overall transfer coefficients even when the equilibrium lines are curved. This procedure is empirical, since the theory indicates that in such cases the rates of transfer may not vary in direct proportion to the overall bulk concentration differences ( $y - y^\circ$ ) and ( $x^\circ - x$ ) at all concentration levels even though the rates may be proportional to the concentration difference in each phase taken separately, i.e.,  $(x_i - x)$  and  $(y - y_i)$ .

In most types of separation equipment such as packed or spray towers, the interfacial area that is effective for mass transfer cannot be accurately determined. For this reason it is customary to report experimentally observed rates of transfer in terms of transfer coefficients based on a unit volume of the apparatus rather than on a unit of interfacial area. Such volumetric coefficients are designated as  $K_{Ca}$ ,  $k_{La}$ , etc., where  $a$  represents the interfacial area per unit volume of the apparatus. Experimentally observed variations in the values of these volumetric coefficients with variations in flow rates, type of packing, etc., may be due as much to changes in the effective value of  $a$  as to changes in  $k$ . Calculation of the overall coefficients from the individual volumetric coefficients is made by means of the equations

$$1/K_{Ca} = (1/k_{Ca} + m/k_{La}) \quad (5-272)$$

$$1/K_{La} = (1/k_{La} + 1/mk_{Ca}) \quad (5-273)$$

Because of the wide variation in equilibrium, the variation in the values of  $m$  from one system to another can have an important effect on the overall coefficient and on the selection of the type of equipment to use. For example, if  $m$  is large, the liquid-phase part of the overall resistance might be extremely large where  $k_L$  might be relatively small. This kind of reasoning must be applied with caution, however, since species with different equilibrium characteristics are separated under different

operating conditions. Thus, the effect of changes in  $m$  on the overall resistance to mass transfer may partly be counterbalanced by changes in the individual specific resistances as the flow rates are changed.

**Mass-Transfer Principles: Concentrated Systems** When solute concentrations in the gas and/or liquid phases are large, the equations derived above for dilute systems no longer are applicable. The correct equations to use for concentrated systems are as follows:

$$N_A = \hat{k}_G(y - y_i)/y_{BM} = \hat{k}_L(x_i - x)/x_{BM} \\ = \hat{K}_G(y - y^\circ)/y_{BM}^\circ = \hat{K}_L(x^\circ - x)/x_{BM}^\circ \quad (5-274)$$

where ( $N_B = 0$ )

$$y_{BM} = \frac{(1 - y) - (1 - y_i)}{\ln [(1 - y)/(1 - y_i)]} \quad (5-275)$$

$$y_{BM}^\circ = \frac{(1 - y) - (1 - y^\circ)}{\ln [(1 - y)/(1 - y^\circ)]} \quad (5-276)$$

$$x_{BM} = \frac{(1 - x) - (1 - x_i)}{\ln [(1 - x)/(1 - x_i)]} \quad (5-277)$$

$$x_{BM}^\circ = \frac{(1 - x) - (1 - x^\circ)}{\ln [(1 - x)/(1 - x^\circ)]} \quad (5-278)$$

and where  $\hat{k}_G$  and  $\hat{k}_L$  are the gas-phase and liquid-phase mass-transfer coefficients for concentrated systems and  $\hat{K}_G$  and  $\hat{K}_L$  are the overall gas-phase and liquid-phase mass-transfer coefficients for concentrated systems. These coefficients are defined later in Eqs. (5-281) to (5-283).

The factors  $y_{BM}$  and  $x_{BM}$  arise from the fact that, in the diffusion of a solute through a second stationary layer of insoluble fluid, the resistance to diffusion varies in proportion to the concentration of the insoluble stationary fluid, approaching zero as the concentration of the insoluble fluid approaches zero. See Eq. (5-198).

The factors  $y_{BM}^\circ$  and  $x_{BM}^\circ$  cannot be justified on the basis of mass-transfer theory since they are based on overall resistances. These factors therefore are included in the equations by analogy with the corresponding film equations.

In dilute systems the logarithmic-mean insoluble-gas and nonvolatile-liquid concentrations approach unity, and Eq. (5-274) reduces to the dilute-system formula. For equimolar counter diffusion (e.g., binary distillation), these log-mean factors should be omitted. See Eq. (5-197).

Substitution of Eqs. (5-275) through (5-278) into Eq. (5-274) results in the following simplified formula:

$$N_A = \hat{k}_G \ln [(1 - y_i)/(1 - y)] \\ = \hat{K}_G \ln [(1 - y^\circ)/(1 - y)] \\ = \hat{k}_L \ln [(1 - x)/(1 - x_i)] \\ = \hat{K}_L \ln [(1 - x^\circ)/(1 - x)] \quad (5-279)$$

Note that the units of  $\hat{k}_G$ ,  $\hat{K}_G$ ,  $\hat{k}_L$ , and  $\hat{K}_L$  are all identical to each other, i.e.,  $\text{kmol}/(s \cdot \text{m}^2)$  in SI units.

The equation for computing the interfacial gas and liquid compositions in concentrated systems is

$$(y - y_i)/(x_i - x) = \hat{k}_L y_{BM} / \hat{k}_G x_{BM} \\ = L_M H_C y_{BM} / G_M H_L x_{BM} = k_L / k_G \quad (5-280)$$

This equation is identical to the one for dilute systems since  $\hat{k}_G = k_G y_{BM}$  and  $\hat{k}_L = k_L x_{BM}$ . Note, however, that when  $\hat{k}_G$  and  $\hat{k}_L$  are given, the equation must be solved by trial and error, since  $x_{BM}$  contains  $x_i$  and  $y_{BM}$  contains  $y_i$ .

The overall gas-phase and liquid-phase mass-transfer coefficients for concentrated systems are computed according to the following equations:

$$\frac{1}{\hat{K}_G} = \frac{y_{BM}}{y_{BM}^\circ} \frac{1}{\hat{k}_G} + \frac{x_{BM}}{y_{BM}^\circ} \frac{1}{\hat{k}_L} \left( \frac{y_i - y^\circ}{x_i - x} \right) \quad (5-281)$$

$$\frac{1}{\hat{K}_L} = \frac{x_{BM}}{x_{BM}^\circ} \frac{1}{\hat{k}_L} + \frac{y_{BM}}{x_{BM}^\circ} \frac{1}{\hat{k}_G} \left( \frac{x^\circ - x_i}{y - y_i} \right) \quad (5-282)$$

When the equilibrium curve is a straight line, the terms in parentheses can be replaced by the slope  $m$  or  $1/m$  as before. In this case the

overall mass-transfer coefficients for concentrated systems are related to each other by the equation

$$\hat{K}_L = m \hat{K}_G (x_{BM}^{\circ} / y_{BM}^{\circ}) \quad (5-283)$$

All these equations reduce to their dilute-system equivalents as the inert concentrations approach unity in terms of mole fractions of inert concentrations in the fluids.

**HTU (Height Equivalent to One Transfer Unit)** Frequently the values of the individual coefficients of mass transfer are so strongly dependent on flow rates that the quantity obtained by dividing each coefficient by the flow rate of the phase to which it applies is more nearly constant than the coefficient itself. The quantity obtained by this procedure is called the height equivalent to one transfer unit, since it expresses in terms of a single length dimension the height of apparatus required to accomplish a separation of standard difficulty.

The following relations between the transfer coefficients and the values of HTU apply:

$$H_G = G_M / k_G a y_{BM} = G_M / \hat{K}_G a \quad (5-284)$$

$$H_{OG} = G_M / K_G a y_{BM}^{\circ} = G_M / \hat{K}_G a \quad (5-285)$$

$$H_L = L_M / k_L a x_{BM} = L_M / \hat{K}_L a \quad (5-286)$$

$$H_{OL} = L_M / K_L a x_{BM}^{\circ} = L_M / \hat{K}_L a \quad (5-287)$$

The equations that express the addition of individual resistances in terms of HTUs, applicable to either dilute or concentrated systems, are

$$H_{OG} = \frac{y_{BM}}{y_{BM}^{\circ}} H_G + \frac{m G_M}{L_M} \frac{x_{BM}}{y_{BM}^{\circ}} H_L \quad (5-288)$$

$$H_{OL} = \frac{x_{BM}}{x_{BM}^{\circ}} H_L + \frac{L_M}{m G_M} \frac{y_{BM}}{x_{BM}^{\circ}} H_G \quad (5-289)$$

These equations are strictly valid only when  $m$ , the slope of the equilibrium curve, is constant, as noted previously.

**NTU (Number of Transfer Units)** The NTU required for a given separation is closely related to the number of theoretical stages or plates required to carry out the same separation in a stagewise or plate-type apparatus. For equimolar counterdiffusion, such as in a binary distillation, the number of overall gas-phase transfer units  $N_{OG}$  required for changing the composition of the vapor stream from  $y_1$  to  $y_2$  is

$$N_{OG} = \int_{y_2}^{y_1} \frac{dy}{y - y^{\circ}} \quad (5-290)$$

When diffusion is in one direction only, as in the absorption of a soluble component from an insoluble gas,

$$N_{OG} = \int_{y_2}^{y_1} \frac{y_{BM}^{\circ} dy}{(1 - y)(y - y^{\circ})} \quad (5-291)$$

The total height of packing required is then

$$h_T = H_{OG} N_{OG} \quad (5-292)$$

When it is known that  $H_{OG}$  varies appreciably within the tower, this term must be placed inside the integral in Eqs. (5-290) and (5-291) for accurate calculations of  $h_T$ . For example, the packed-tower design equation in terms of the overall gas-phase mass-transfer coefficient for absorption would be expressed as follows:

$$h_T = \int_{y_2}^{y_1} \left[ \frac{G_M}{K_G a y_{BM}^{\circ}} \right] \frac{y_{BM}^{\circ} dy}{(1 - y)(y - y^{\circ})} \quad (5-293)$$

where the first term under the integral can be recognized as the HTU term. Convenient solutions of these equations for special cases are discussed later.

**Definitions of Mass-Transfer Coefficients  $\hat{K}_G$  and  $\hat{K}_L$**  The mass-transfer coefficient is defined as the ratio of the molar mass flux  $N_A$  to the concentration driving force. This leads to many different ways of defining these coefficients. For example, gas-phase mass-transfer rates may be defined as

$$N_A = k_G (y - y_i) = k'_G (p - p_i) = \hat{k}_G (y - y_i) / y_{BM} \quad (5-294)$$

where the units (SI) of  $k_G$  are  $\text{kmol}/[(\text{s}\cdot\text{m}^2)(\text{mole fraction})]$ , the units of

$k'_G$  are  $\text{kmol}/[(\text{s}\cdot\text{m}^2)(\text{kPa})]$ , and the units of  $\hat{k}_G$  are  $\text{kmol}/(\text{s}\cdot\text{m}^2)$ . These coefficients are related to each other as follows:

$$k_G = k_C y_{BM} = k'_G p_T y_{BM} \quad (5-295)$$

where  $p_T$  is the total system pressure (it is assumed here that Dalton's law of partial pressures is valid).

In a similar way, liquid-phase mass-transfer rates may be defined by the relations

$$N_A = k_L (x_i - x) = k'_L (c_i - c) = \hat{k}_L (x_i - x) / x_{BM} \quad (5-296)$$

where the units (SI) of  $k_L$  are  $\text{kmol}/[(\text{s}\cdot\text{m}^2)(\text{mole fraction})]$ , the units of  $k'_L$  are  $\text{kmol}/[(\text{s}\cdot\text{m}^2)(\text{kmol}/\text{m}^3)]$  or meters per second, and the units of  $\hat{k}_L$  are  $\text{kmol}/(\text{s}\cdot\text{m}^2)$ . These coefficients are related as follows:

$$\hat{k}_L = k_L x_{BM} = k'_L \bar{\rho}_L x_{BM} \quad (5-297)$$

where  $\bar{\rho}_L$  is the molar density of the liquid phase in units (SI) of kilomoles per cubic meter. Note that, for dilute solutions where  $x_{BM} \doteq 1$ ,  $k_L$  and  $\hat{k}_L$  will have identical numerical values. Similarly, for dilute gases  $\hat{k}_G \doteq k_G$ .

**Simplified Mass-Transfer Theories** In certain simple situations, the mass-transfer coefficients can be calculated from first principles. The film, penetration, and surface-renewal theories are attempts to extend these theoretical calculations to more complex situations. Although these theories are often not accurate, they are useful to provide a physical picture for variations in the mass-transfer coefficient.

For the special case of steady-state unidirectional diffusion of a component through an inert-gas film in an ideal-gas system, the rate of mass transfer is derived as

$$N_A = \frac{D_{AB} p_T}{RT \delta_C} \frac{(y - y_i)}{y_{BM}} = \frac{D_{AB} p_T}{RT \delta_C} \ln \frac{1 - y_i}{1 - y} \quad (5-298)$$

where  $D_{AB}$  is the diffusion coefficient or "diffusivity,"  $\delta_C$  is the "effective" thickness of a stagnant-gas layer which would offer a resistance to molecular diffusion equal to the experimentally observed resistance, and  $R$  is the gas constant. [Nernst, *Z. Phys. Chem.*, **47**, 52 (1904); Whitman, *Chem. Mat. Eng.*, **29**, 149 (1923), and Lewis and Whitman, *Ind. Eng. Chem.*, **16**, 1215 (1924)].

The film thickness  $\delta_C$  depends primarily on the hydrodynamics of the system and hence on the Reynolds number and the Schmidt number. Thus, various correlations have been developed for different geometries in terms of the following dimensionless variables:

$$N_{Sh} = \hat{k}_G R T d / D_{AB} p_T = f(N_{Re}, N_{Sc}) \quad (5-299)$$

where  $N_{Sh}$  is the Sherwood number,  $N_{Re}$  ( $= Gd/\mu_C$ ) is the Reynolds number based on the characteristic length  $d$  appropriate to the geometry of the particular system; and  $N_{Sc}$  ( $= \mu_C/\rho_C D_{AB}$ ) is the Schmidt number.

According to this analysis one can see that for gas-absorption problems, which often exhibit unidirectional diffusion, the most appropriate driving-force expression is of the form  $(y - y_i)/y_{BM}$ , and the most appropriate mass-transfer coefficient is therefore  $\hat{k}_G$ . This concept is to be found in all the key equations for the design of mass-transfer equipment.

The Sherwood-number relation for gas-phase mass-transfer coefficients as represented by the film diffusion model in Eq. (5-299) can be rearranged as follows:

$$N_{Sh} = (\hat{k}_G / G_M) N_{Re} N_{Sc} = N_{St} N_{Re} N_{Sc} = f(N_{Re}, N_{Sc}) \quad (5-300)$$

where  $N_{St} = \hat{k}_G / G_M = k'_G p_{BM} / G_M$  is known as the Stanton number. This equation can now be stated in the alternative functional forms

$$N_{St} = \hat{k}_G / G_M = g(N_{Re}, N_{Sc}) \quad (5-301)$$

$$j_D = N_{St} \cdot N_{Sc}^{2/3} \quad (5-302)$$

where  $j$  is the Chilton-Colburn "j factor" for mass transfer (discussed later).

The important point to note here is that the gas-phase mass-transfer coefficient  $\hat{k}_G$  depends principally upon the transport properties of the fluid ( $N_{Sc}$ ) and the hydrodynamics of the particular system involved ( $N_{Re}$ ). It also is important to recognize that specific mass-transfer correlations can be derived only in conjunction with the

investigator's particular assumptions concerning the numerical values of the effective interfacial area  $a$  of the packing.

The stagnant-film model discussed previously assumes a steady state in which the local flux across each element of area is constant; i.e., there is no accumulation of the diffusing species within the film. Higbie [*Trans. Am. Inst. Chem. Eng.*, **31**, 365 (1935)] pointed out that industrial contactors often operate with repeated brief contacts between phases in which the contact times are too short for the steady state to be achieved. For example, Higbie advanced the theory that in a packed tower the liquid flows across each packing piece in laminar flow and is remixed at the points of discontinuity between the packing elements. Thus, a fresh liquid surface is formed at the top of each piece, and as it moves downward, it absorbs gas at a decreasing rate until it is mixed at the next discontinuity. This is the basis of penetration theory.

If the velocity of the flowing stream is uniform over a very deep region of liquid (total thickness,  $\delta_T \gg \sqrt{Dt}$ ), the time-averaged mass-transfer coefficient according to penetration theory is given by

$$k'_L = 2\sqrt{D_L/\pi t} \quad (5-303)$$

where  $k'_L$  = liquid-phase mass-transfer coefficient,  $D_L$  = liquid-phase diffusion coefficient, and  $t$  = contact time.

In practice, the contact time  $t$  is not known except in special cases in which the hydrodynamics are clearly defined. This is somewhat similar to the case of the stagnant-film theory in which the unknown quantity is the thickness of the stagnant layer  $\delta$  (in film theory, the liquid-phase mass-transfer coefficient is given by  $k'_L = D_L/\delta$ ).

The penetration theory predicts that  $k'_L$  should vary by the square root of the molecular diffusivity, as compared with film theory, which predicts a first-power dependency on  $D$ . Various investigators have reported experimental powers of  $D$  ranging from 0.5 to 0.75, and the Chilton-Colburn analogy suggests a  $2/3$  power.

Penetration theory often is used in analyzing absorption with chemical reaction because it makes no assumption about the depths of penetration of the various reacting species, and it gives a more accurate result when the diffusion coefficients of the reacting species are not equal. When the reaction process is very complex, however, penetration theory is more difficult to use than film theory, and the latter method normally is preferred.

Danckwerts [*Ind. Eng. Chem.*, **42**, 1460 (1951)] proposed an extension of the penetration theory, called the surface renewal theory, which allows for the eddy motion in the liquid to bring masses of fresh liquid continually from the interior to the surface, where they are exposed to the gas for finite lengths of time before being replaced. In his development, Danckwerts assumed that every element of fluid has an equal chance of being replaced regardless of its age. The Danckwerts model gives

$$k'_L = \sqrt{Ds} \quad (5-304)$$

where  $s$  = fractional rate of surface renewal.

Note that both the penetration and the surface-renewal theories predict a square-root dependency on  $D$ . Also, it should be recognized that values of the surface-renewal rate  $s$  generally are not available, which presents the same problems as do  $\delta$  and  $t$  in the film and penetration models.

The predictions of correlations based on the film model often are nearly identical to predictions based on the penetration and surface-renewal models. Thus, in view of its relative simplicity, the film model normally is preferred for purposes of discussion or calculation. It should be noted that none of these theoretical models has proved adequate for making a priori predictions of mass-transfer rates in packed towers, and therefore empirical correlations such as those outlined later in Table 5-24 must be employed.

**Mass-Transfer Correlations** Because of the tremendous importance of mass transfer in chemical engineering, a very large number of studies have determined mass-transfer coefficients both empirically and theoretically. Some of these studies are summarized in Tables 5-17 to 5-24. Each table is for a specific geometry or type of contactor, starting with flat plates, which have the simplest geometry (Table 5-17); then wetted wall columns (Table 5-18); flow in pipes and ducts (Table 5-19); submerged objects (Table 5-20); drops and

bubbles (Table 5-21); agitated systems (Table 5-22); packed beds of particles for adsorption, ion exchange, and chemical reaction (Table 5-23); and finishing with packed bed two-phase contactors for distillation, absorption and other unit operations (Table 5-24). Although extensive, these tables are not meant to be encyclopedic, but a variety of different configurations are shown to provide a flavor of the range of correlations available. These correlations include transfer to or from one fluid and either a second fluid or a solid. Many of the correlations are for  $k_L$  and  $k_G$  values obtained from dilute systems where  $x_{BM} \approx 1.0$  and  $y_{BM} \approx 1.0$ . The most extensive source for older mass-transfer correlations in a variety of geometries is Skelland (*Diffusional Mass Transfer*, 1974). The extensive review of bubble column systems (see Table 5-21) by Shah et al. [*AIChE J.*, **28**, 353 (1982)] includes estimation of bubble size, gas holdup, interfacial area  $k_L a$ , and liquid dispersion coefficient. For correlations for particle-liquid mass transfer in stirred tanks (part of Table 5-22) see the review by Pangarkar et al. [*Ind. Eng. Chem. Res.*, **41**, 4141 (2002)]. For mass transfer in distillation, absorption, and extraction in packed beds (Table 5-24), see also the appropriate sections in this handbook and the review by Wang, Yuan, and Yu [*Ind. Eng. Chem. Res.*, **44**, 8715 (2005)]. For simple geometries, one may be able to determine a theoretical (T) form of the mass-transfer correlation. For very complex geometries, only an empirical (E) form can be found. In systems of intermediate complexity, semiempirical (S) correlations where the form is determined from theory and the coefficients from experiment are often useful. Although the major limitations and constraints in use are usually included in the tables, obviously many details cannot be included in this summary form. Readers are strongly encouraged to check the references before using the correlations in important situations. Note that even authoritative sources occasionally have typographical errors in the fairly complex correlation equations. Thus, it is a good idea to check several sources, including the original paper. The references will often include figures comparing the correlations with data. These figures are very useful since they provide a visual picture of the scatter in the data.

Since there are often several correlations that are applicable, how does one choose the correlation to use? First, the engineer must determine which correlations are closest to the current situation. This involves recognizing the similarity of geometries, which is often challenging, and checking that the range of parameters in the correlation is appropriate. For example, the Bravo, Rocha, and Fair correlation for distillation with structured packings with triangular cross-sectional channels (Table 5-24-H) uses the Johnstone and Pigford correlation for rectification in vertical wetted wall columns (Table 5-18-F). Recognizing that this latter correlation pertains to a rather different application and geometry was a nontrivial step in the process of developing a correlation. If several correlations appear to be applicable, check to see if the correlations have been compared to each other and to the data. When a detailed comparison of correlations is not available, the following heuristics may be useful:

1. Mass-transfer coefficients are derived from models. They must be employed in a similar model. For example, if an arithmetic concentration difference was used to determine  $k$ , that  $k$  should only be used in a mass-transfer expression with an arithmetic concentration difference.
2. Semiempirical correlations are often preferred to purely empirical or purely theoretical correlations. Purely empirical correlations are dangerous to use for extrapolation. Purely theoretical correlations may predict trends accurately, but they can be several orders of magnitude off in the value of  $k$ .
3. Correlations with broader data bases are often preferred.
4. The analogy between heat and mass transfer holds over wider ranges than the analogy between mass and momentum transfer. Good heat transfer data (without radiation) can often be used to predict mass-transfer coefficients.
5. More recent data is often preferred to older data, since end effects are better understood, the new correlation often builds on earlier data and analysis, and better measurement techniques are often available.
6. With complicated geometries, the product of the interfacial area per volume and the mass-transfer coefficient is required. Correlations of  $ka_p$  or of HTU are more accurate than individual correlations of  $k$  and

**TABLE 5-18 Mass-Transfer Correlations for Falling Films with a Free Surface in Wetted Wall Columns—Transfer between Gas and Liquid**

| Situation  | Correlation  | Comments<br>E = Empirical, S = Semiempirical, T = Theoretical   | References*  |
|--|--|---|--|
| A. Laminar, vertical wetted wall column  | $N_{Sh,avg} = \frac{K'_m x}{D} \approx 3.41 \frac{x}{\delta_{film}}$ (first term of infinite series)<br>$\delta_{film} = \left( \frac{3\mu Q}{w\rho g} \right)^{1/3} = \text{film thickness}$ $N_{Re, film} = \frac{4Q\rho}{w\mu} < 20$  | [T] Low rates M.T. Use with log mean concentration difference. Parabolic velocity distribution in films.<br>$w$ = film width (circumference in column)<br>Derived for flat plates, used for tubes if<br>$r_{tube} \left( \frac{\rho g}{2\sigma} \right)^{1/2} > 3.0$ . $\sigma$ = surface tension<br>If $N_{Re, film} > 20$ , surface waves and rates increase. An approximate solution $D_{apparent}$ can be used. Ripples are suppressed with a wetting agent good to $N_{Re} = 1200$ . | [138] p. 78<br>[141] p. 137<br>[152] p. 50   |
| B. Turbulent, vertical wetted wall column  | $N_{Sh,avg} = \frac{K'_m d_t}{D} = 0.023 N_{Re}^{0.83} N_{Sc}^{0.44}$ A coefficient 0.0163 has also been reported using $N_{Re'}$ , where $v = v$ of gas relative to liquid film.  | [E] Use with log mean concentration difference for correlations in B and D. $N_{Re}$ is for gas. $N_{Sc}$ for vapor in gas. $2000 < N_{Re} \leq 35,000$ , $0.6 \leq N_{Sc} \leq 2.5$ . Use for gases, $d_t$ = tube diameter.  | [68]<br>[77] p. 181<br>[138] p. 211<br>[141] p. 265<br>[149] p. 212<br>[152] p. 71<br>[58] |
| Better fit   | $N_{Sh,avg} = 0.0318 N_{Re}^{0.790} N_{Sc}^{0.5}$  | [S] Reevaluated data  |  |
| C. Turbulent, very short column  | $N_{Sh} = 0.00283 N_{Re,g}^{0.5} N_{Sc,g}^{0.06} N_{Re,liq}$ $N_{Sh} = k_g(d_{tube} - 2\delta)/D$ $N_{Re,g} = \rho_g u_g (d_{tube} - 2\delta)/\mu_g$ $N_{Re,liq} = \rho_{liq} Q_{liq} / [\pi \mu (d_{tube} - 2\delta)]$  | [E] Evaporation data<br>$N_{Sh,g} = 11$ to $65$ , $N_{Re,g} = 2400$ to $9100$<br>$N_{Re,liq} = 110$ to $480$ , $N_{Sc,g} = 0.62$ to $1.93$<br>$\delta$ = film thickness   | [56]   |
| D. Turbulent, vertical wetted wall column with ripples   | $N_{Sh,avg} = \frac{K'_m d_t}{D} = 0.00814 N_{Re}^{0.83} N_{Sc}^{0.44} \left( \frac{4Q\rho}{w\mu} \right)^{0.15}$ $30 \leq \left( \frac{4Q\rho}{w\mu} \right) < 1200$ $N_{Sh,avg} = \frac{K'_m d_t}{D} = 0.023 N_{Re}^{0.8} N_{Sc}^{1/3}$  | [E] For gas systems with rippling.<br>Fits 5-18-B for $\left( \frac{4Q\rho}{w\mu} \right) = 1000$<br>[E] "Rounded" approximation to include ripples. Includes solid-liquid mass-transfer data to find $1/3$ coefficient on $N_{Sc}$ . May use $N_{Re}^{0.83}$ . Use for liquids. See also Table 5-19.   | [85]<br>[138] p. 213   |
| E. Turbulent, with ripples   | $N_{Sh} = \left( \frac{2}{\pi} \right)^{0.5} N_{Re,\epsilon}^{0.5} N_{Sc}^{0.5}$ $N_{Re,\epsilon} = \dot{\epsilon} L^2 / \nu$  | [E] $\dot{\epsilon}$ = dilation rate of surface = $\frac{\partial v_x^c}{\partial x} + \frac{\partial v_y^c}{\partial y}$   | [150]  |
| F. Rectification in vertical wetted wall column with turbulent vapor flow, Johnstone and Pigford correlation | $N_{Sh,avg} = \frac{k'_c d_{col} p_{BM}}{D_c p} = 0.0328 (N'_{Re})^{0.77} N_{Sc}^{0.33}$ $3000 < N'_{Re} < 40,000, 0.5 < N_{Sc} < 3$ $N'_{Re} = \frac{d_{col} v_{rel} \rho_v}{\mu_v}, v_{rel} = \text{gas velocity relative to liquid film} = \frac{3}{2} u_{avg} \text{ in film}$ | [E] Use logarithmic mean driving force at two ends of column. Based on four systems with gas-side resistance only. $p_{BM}$ = logarithmic mean partial pressure of nondiffusing species $B$ in binary mixture. $p$ = total pressure<br>Modified form is used for structured packings (See Table 5-24-H).  | [84]<br>[138] p. 214<br>[156]  |

\*See the beginning of the "Mass Transfer" subsection for references.

$a_p$  since the measurements are simpler to determine the product  $ka_p$  or HTU.

7. Finally, if a mass-transfer coefficient looks too good to be true, it probably is incorrect.

To determine the mass-transfer rate, one needs the interfacial area in addition to the mass-transfer coefficient. For the simpler geometries, determining the interfacial area is straightforward. For packed beds of particles  $a$ , the interfacial area per volume can be estimated as shown in Table 5-23-A. For packed beds in distillation, absorption, and so on in Table 5-24, the interfacial area per volume is included with the mass-transfer coefficient in the correlations for HTU. For agitated liquid-liquid systems, the interfacial area can be estimated

from the dispersed phase holdup and mean drop size correlations. Godfrey, Obi, and Reeve [*Chem. Engr. Prog.* **85**, 61 (Dec. 1989)] summarize these correlations. For many systems,  $\bar{d}_{drop}/d_{imp} = (\text{const})N_{We}^{-0.6}$  where  $N_{We} = \rho_c N^2 d_{imp}^3 / \sigma$ . Piché, Grandjean, and Larachi [*Ind. Eng. Chem. Res.* **41**, 4911 (2002)] developed two correlations for reconciling the gas-liquid mass-transfer coefficient and interfacial area in randomly packed towers. The correlation for the interfacial area was a function of five dimensionless groups, and yielded a relative error of 22.5 percent for 325 data points. That equation, when combined with a correlation for  $N_{Sh}$  as a function of four dimensionless groups, achieved a relative error of 24.4 percent, for 3455 data points for the product  $k'_c a$ .

\*See the beginning of the "Mass Transfer" subsection for references.

**Effects of Total Pressure on  $k_C$  and  $k_L$ .** The influence of total system pressure on the rate of mass transfer from a gas to a liquid or to a solid has been shown to be the same as would be predicted from stagnant-film theory as defined in Eq. (5-298), where

$$\hat{k}_C = D_{AB} p_T / RT \delta_C \quad (5-305)$$

Since the quantity  $D_{AB} p_T$  is known to be relatively independent of the pressure, it follows that the rate coefficients  $\hat{k}_C$ ,  $k_C y_{BM}$ , and  $K_C p_T y_{BM}$  ( $= k_C p_{BM}$ ) do not depend on the total pressure of the system, subject to the limitations discussed later.

Investigators of tower packings normally report  $k'_C a$  values measured at very low inlet-gas concentrations, so that  $y_{BM} = 1$ , and at total pressures close to 100 kPa (1 atm). Thus, the correct rate coefficient for use in packed-tower designs involving the use of the driving force  $(y - y_i)/y_{BM}$  is obtained by multiplying the reported  $k'_C a$  values by the value of  $p_T$  employed in the actual test unit (e.g., 100 kPa) and *not* the total pressure of the system to be designed.

From another point of view one can correct the reported values of  $k'_C a$  in  $\text{kmol}/[(s \cdot \text{m}^3)(\text{kPa})]$ , valid for a pressure of 101.3 kPa (1 atm), to some other pressure by dividing the quoted values of  $k'_C a$  by the design pressure and multiplying by 101.3 kPa, i.e.,  $(k'_C a \text{ at design pressure } p_T) = (k'_C a \text{ at } 1 \text{ atm}) \times 101.3/p_T$ .

One way to avoid a lot of confusion on this point is to convert the experimentally measured  $k'_C a$  values to values of  $\hat{k}_C a$  straightaway, before beginning the design calculations. A design based on the rate coefficient  $\hat{k}_C a$  and the driving force  $(y - y_i)/y_{BM}$  will be independent of the total system pressure with the following limitations: caution should be employed in assuming that  $\hat{k}_C a$  is independent of total pressure for systems having significant vapor-phase non-idealities, for systems that operate in the vicinity of the critical

point, or for total pressures higher than about 3040 to 4050 kPa (30 to 40 atm).

Experimental confirmations of the relative independence of  $\hat{k}_C$  with respect to total pressure have been widely reported. Deviations do occur at extreme conditions. For example, Bretsznajder (*Prediction of Transport and Other Physical Properties of Fluids*, Pergamon Press, Oxford, 1971, p. 343) discusses the effects of pressure on the  $D_{AB} p_T$  product and presents experimental data on the self-diffusion of  $\text{CO}_2$  which show that the  $D$ - $p$  product begins to decrease at a pressure of approximately 8100 kPa (80 atm). For reduced temperatures higher than about 1.5, the deviations are relatively modest for pressures up to the critical pressure. However, deviations are large near the critical point (see also p. 5-52). The effect of pressure on the gas-phase viscosity is also negligible for pressures below about 5060 kPa (50 atm).

For the liquid-phase mass-transfer coefficient  $k_L$ , the effects of total system pressure can be ignored for all practical purposes. Thus, when using  $\hat{k}_C$  and  $\hat{k}_L$  for the design of gas absorbers or strippers, the primary pressure effects to consider will be those which affect the equilibrium curves and the values of  $m$ . If the pressure changes affect the hydrodynamics, then  $\hat{k}_C$ ,  $\hat{k}_L$ , and  $a$  can all change significantly.

**Effects of Temperature on  $k_C$  and  $k_L$ .** The Stanton-number relationship for gas-phase mass transfer in packed beds, Eq. (5-301), indicates that for a given system geometry the rate coefficient  $\hat{k}_C$  depends only on the Reynolds number and the Schmidt number. Since the Schmidt number for a gas is approximately independent of temperature, the principal effect of temperature upon  $\hat{k}_C$  arises from changes in the gas viscosity with changes in temperature. For normally encountered temperature ranges, these effects will be small owing to the fractional powers involved in Reynolds-number terms (see Tables 5-17 to 5-24). It thus can be concluded that for all

## 5-70 HEAT AND MASS TRANSFER

**TABLE 5-20 Mass-Transfer Correlations for Flow Past Submerged Objects (Concluded)**

| Situation   | Correlation   | Comments<br>E = Empirical, S = Semiempirical, T = Theoretical   | References°   |
|---|---|---|---|
| J. Rotating cylinder in an infinite liquid, no forced flow  | $j_D = \frac{k'}{v} N_{Sc}^{0.644} = 0.0791 N_{Re}^{-0.30}$ <p>Results presented graphically to <math>N_{Re} = 241,000</math>.</p> $N_{Re} = \frac{v d_{cyl} \rho}{\mu} \text{ where } v = \frac{\omega d_{cyl}}{2} = \text{peripheral velocity}$   | <p>[E] Used with arithmetic concentration difference. Useful geometry in electrochemical studies.</p> <p><math>112 &lt; N_{Re} \leq 100,000</math>. <math>835 &lt; N_{Sc} &lt; 11490</math></p> <p><math>k'</math> = mass-transfer coefficient, cm/s; <math>\omega</math> = rotational speed, radian/s.</p>   | <p>[60]</p> <p>[138] p. 238</p>                           |
| K. Stationary or rotating cylinder for air  | <p>Stationary:</p> $N_{Sh,avg} = AN_{Re}^c Sc^{1/3}$ <p><math>2.0 \times 10^4 \leq N_{Re} \leq 2.5 \times 10^5</math>; <math>d/H = 0.3</math>, <math>Tu = 0.6\%</math></p> <p><math>A = 0.0539</math>, <math>c = 0.771</math> [114]</p> <p><math>A</math> and <math>c</math> depend on geometry [37]</p> <p>Rotating in still air:</p> $N_{Sh,avg} = 0.169 N_{Re, \omega}^{2/3}$ <p><math>1.0E4 \leq N_{Re, \omega} \leq 1.0E5</math>; <math>N_{Sc} \approx 2.0</math>; <math>N_{Gr} \approx 2.0 \times 10^6</math></p> | <p>[E] Reasonable agreement with data of other investigators. <math>d</math> = diameter of cylinder; <math>H</math> = height of wind tunnel, <math>Tu</math> of = turbulence level, <math>N_{Re, \omega}</math> = rotational Reynold's number = <math>u_{\omega} d \rho / \mu</math>, <math>u_{\omega}</math> = cylinder surface velocity. Also correlations for two-dimensional slot jet flow [114]. For references to other correlations see [37].</p>  | <p>[37]</p> <p>[114]</p>                                  |
| L. Oblate spheroid, forced convection   | $j_D = \frac{N_{Sh}}{N_{Re} N_{Sc}^{1/3}} = 0.74 N_{Re}^{-0.5}$ $N_{Re} = \frac{d_{ch} v \rho}{\mu}, d_{ch} = \frac{\text{total surface area}}{\text{perimeter normal to flow}}$ <p>e.g., for cube with side length <math>a</math>, <math>d_{ch} = 1.27a</math>.</p> $N_{Sh} = \frac{k' d_{ch}}{D}$   | <p>[E] Used with arithmetic concentration difference.</p> <p><math>120 \leq N_{Re} \leq 6000</math>; standard deviation 2.1%.</p> <p>Eccentricities between 1:1 (spheres) and 3:1. Oblate spheroid is often approximated by drops.</p>  | <p>[141] p. 284</p> <p>[142]</p>                          |
| M. Other objects, including prisms, cubes, hemispheres, spheres, and cylinders; forced convection | $j_D = 0.692 N_{Re,p}^{-0.486}, N_{Re,p} = \frac{v d_{ch} \rho}{\mu}$ <p>Terms same as in 5-20-J.</p>   | <p>[E] Used with arithmetic concentration difference. Agrees with cylinder and oblate spheroid results, <math>\pm 15\%</math>. Assumes molecular diffusion and natural convection are negligible.</p> <p><math>500 \leq N_{Re,p} \leq 5000</math>. Turbulent.</p>   | <p>[88] p. 115</p> <p>[141] p. 285</p> <p>[111] [112]</p> |
| N. Other objects, molecular diffusion limits  | $N_{Sh} = \frac{k' d_{ch}}{D} = A$  | <p>[T] Use with arithmetic concentration difference. Hard to reach limits in experiments. Spheres and cubes <math>A = 2</math>, tetrahedrons <math>A = 2\sqrt{6}</math> octahedrons <math>2\sqrt{2}</math>.</p>   | <p>[88] p. 114</p>  |
| O. Shell side of microporous hollow fiber module for solvent extraction                           | $N_{Sh} = \beta [d_h (1 - \phi) / L] N_{Re}^{0.6} N_{Sc}^{0.33}$ $N_{Sh} = \frac{\bar{K} d_h}{D}$ $N_{Re} = \frac{d_h v \rho}{\mu}, \bar{K} = \text{overall mass-transfer coefficient}$ <p><math>\beta = 5.8</math> for hydrophobic membrane.</p> <p><math>\beta = 6.1</math> for hydrophilic membrane.</p>   | <p>[E] Use with logarithmic mean concentration difference.</p> <p><math>d_h</math> = hydraulic diameter</p> $= \frac{4 \times \text{cross-sectional area of flow}}{\text{wetted perimeter}}$ <p><math>\phi</math> = packing fraction of shell side.<br/> <math>L</math> = module length.<br/>         Based on area of contact according to inside or outside diameter of tubes depending on location of interface between aqueous and organic phases. Can also be applied to gas-liquid systems with liquid on shell side.</p> | <p>[118]</p>  |

See Table 5-23 for flow in packed beds.

| M. Liquid drop in immiscible liquid, free rise or fall, continuous phase coefficient, circulating single drops | $N_{Sh,c} = \frac{k'_{L,c} d_p}{D_c}$<br>$= \left[ 2 + 0.463 N_{Re,drop}^{0.484} N_{Sc,c}^{0.330} \left(\frac{d_p g^{1/3}}{D_c^2}\right)^{0.072} \right] F$<br>$F = 0.281 + 1.615K + 3.73K^2 - 1.874K$<br>$K = N_{Re,drop}^{1/8} \left(\frac{\mu_c}{\mu_d}\right)^{1/4} \left(\frac{\mu_c v_s}{\sigma g_c}\right)^{1/6}$  | [E] Used as an arithmetic concentration difference.<br>$N_{Re,drop} = \frac{d_p v_s \rho_c}{\mu_c}$<br>Solid sphere form with correction factor $F$ .   | [82]                                  |
| N. Same as 5-21-M, circulating, single drop  | $N_{Sh} = \frac{k_{L,c} d_p}{D_c} = 0.6 \left(\frac{\rho_c}{M_c}\right)_{av} N_{Re,drop}^{1/2} N_{Sc,c}^{1/2}$  | [E] Used as an arithmetic concentration difference. Low $\sigma$ .  | [141] p. 407                          |
| O. Same as 5-21-M, circulating swarm of drops  | $k_{L,c} = 0.725 \left(\frac{\rho_c}{M_c}\right)_{av} N_{Re,drop}^{-0.43} N_{Sc,c}^{-0.58} v_s (1 - \phi_d)$  | [E] Used as an arithmetic concentration difference. Low $\sigma$ , disperse-phase holdup of drop swarm. $\phi_d$ = volume fraction dispersed phase.   | [141] p. 407<br>[144] p. 436          |
| P. Liquid drops in immiscible liquid, free rise or fall, discontinuous phase coefficient, oscillating drops    | $N_{Sh} = \frac{k_{L,d,osc} d_p}{D_d}$<br>$= 0.32 \left(\frac{\rho_d}{M_d}\right)_{av} \left(\frac{4D_d t}{d_p^2}\right)^{-0.14} N_{Re,drop}^{0.68} \left(\frac{\sigma^3 g_c^2 \rho_c^2}{g \mu_c^4 \Delta \rho}\right)^{0.10}$  | [E] Used with a log mean mole fraction difference. Based on ends of extraction column.<br>$N_{Re,drop} = \frac{d_p v_s \rho_c}{\mu_c}$ , $411 \leq N_{Re} \leq 3114$<br>$d_p$ = diameter of sphere with volume of drop. Average absolute deviation from data, 10.5%.<br>Low interfacial tension (3.5–5.8 dyn), $\mu_c < 1.35$ centipoise. | [141] p. 406<br>[144] p. 435<br>[145] |
| Q. Same as 5-21-P  | $k_{L,d,osc} = \frac{0.00375 v_s}{1 + \mu_d / \mu_c}$   | [T] Use with log mean concentration difference. Based on end of extraction column. No continuous phase resistance. $k_{L,d,osc}$ in cm/s, $v_s$ = drop velocity relative to continuous phase.   | [138] p. 228<br>[141] p. 405          |
| R. Single liquid drop in immiscible liquid, range rigid to fully circulating                                   | $N_{Sh,c,rigid} = \frac{k_c d_p}{D_c} = 2.43 + 0.774 N_{Re}^{0.5} N_{Sc}^{0.33} + 0.0103 N_{Re} N_{Sc}^{0.33}$<br>$N_{Sh,c,fully\ circular} = \left[ \frac{2}{\pi^{0.5}} \right] N_{Pe,c}^{0.5}$<br>Drops in intermediate range:<br>$\frac{N_{Sh,c} - N_{Sh,c,rigid}}{N_{Sh,c,fully\ circular} - N_{Sh,c,rigid}} = 1 - \exp [-(4.18 \times 10^{-3}) N_{Pe,c}^{0.42}]$ | [E] Allows for slight effect of wake. Rigid drops: $10^4 < N_{Pe,c} < 10^6$<br>Circulating drops: $10 < N_{Re} < 1200$ , $190 < N_{Sc} < 241,000$ , $10^3 < N_{Pe,c} < 10^6$  | [146] p. 58                           |
| S. Coalescing drops in immiscible liquid, discontinuous phase coefficient                                      | $\hat{k}_{d,coal} = 0.173 \frac{d_p}{t_f} \left(\frac{\rho_d}{M_d}\right)_{av} \left(\frac{\mu_d}{\rho_d D_d}\right)^{-1.115} \times \left(\frac{\Delta \rho g d_p^2}{\sigma g_c}\right)^{1.302} \left(\frac{v_s^2 t_f}{D_d}\right)^{0.146}$  | [E] Used with log mean mole fraction difference. 23 data points. Average absolute deviation 25%. $t_f$ = formation time.  | [141] p. 408                          |
| T. Same as 5-21-S, continuous phase coefficient  | $\hat{k}_{c,coal} = 5.959 \times 10^{-4} \left(\frac{\rho}{M}\right)_{av} \times \left(\frac{D_c}{t_f}\right)^{0.5} \left(\frac{\rho_d u_s^3}{g \mu_c}\right)^{0.332} \left(\frac{d_p^2 \rho_c \rho_d v_s^3}{\mu_d \sigma g_c}\right)^{0.525}$  | [E] Used with log mean mole fraction difference. 20 data points. Average absolute deviation 22%.  | [141] p. 409                          |

TABLE 5-21 Mass-Transfer Correlations for Drops, Bubbles, and Bubble Columns (Continued)

| Conditions  | Correlations   | Comments<br>E = Empirical, S = Semiempirical, T = Theoretical   | References°   |
|---|--|---|---|
| U. Single liquid drops in gas, gas side coefficient   | $\frac{\hat{k}_g M_g d_p P}{D_{\text{gas}} \rho_g} = 2 + AN_{Re,g}^{1/2} N_{Sc,g}^{1/3}$<br>$A = 0.552 \text{ or } 0.60.$<br>$N_{Re,g} = \frac{d_p \rho_g v_s}{\mu_g}$   | [E] Used for spray drying (arithmetic partial pressure difference).<br>$v_s$ = slip velocity between drop and gas stream.<br>Sometimes written with $M_g P / \rho_g = RT$ .   | [90] p. 388<br>[121]                                    |
| V. Single water drop in air, liquid side coefficient  | $k_L = 2 \left( \frac{D_L}{\pi t} \right)^{1/2}$ , short contact times<br>$k_L = 10 \frac{D_L}{d_p}$ , long contact times  | [T] Use arithmetic concentration difference. Penetration theory. $t$ = contact time of drop. Gives plot for $k_C a$ also. Air-water system.   | [90] p. 389   |
| W. Single bubbles of gas in liquid, continuous phase coefficient, very small bubbles              | $N_{Sh} = \frac{k'_c d_b}{D_c} = 1.0(N_{Re} N_{Sc})^{1/3}$   | [T] Solid-sphere Eq. (see Table 5-20-B). $d_b < 0.1$ cm, $k'_c$ is average over entire surface of bubble.   | [105]<br>[138] p. 214                                   |
| X. Same as 5-21-W, medium to large bubbles  | $N_{Sh} = \frac{k'_c d_b}{D_c} = 1.13(N_{Re} N_{Sc})^{1/2}$  | [T] Use arithmetic concentration difference. Droplet equation: $d_b > 0.5$ cm.  | [138] p. 231  |
| Y. Same as 5-21-X   | $N_{Sh} = \frac{k'_c d_b}{D_c} = 1.13(N_{Re} N_{Sc})^{1/2} \left[ \frac{d_b}{0.45 + 0.2d_b} \right]$<br>$500 \leq N_{Re} \leq 8000$  | [S] Use arithmetic concentration difference. Modification of above (X), $d_b > 0.5$ cm. No effect SAA for $d_p > 0.6$ cm.   | [83][138]<br>p. 231                                     |
| Z. Taylor bubbles in single capillaries (square or circular)                                      | $k_L a = 4.5 \left( \frac{Du_C}{L_{uc}} \right)^{1/2} \frac{1}{d_c}$<br>Applicable $\left( \frac{u_C + u_L}{L_{slug}} \right)^{0.5} > 3s^{-0.5}$   | [E] Air-water<br>$L_{uc}$ = unit cell length, $L_{slug}$ = slug length, $d_c$ = capillary i.d.<br>For most data $k_L a \pm 20\%$ .  | [153]   |
| AA. Gas-liquid mass transfer in monoliths   | $k_L a \approx 0.1 \left( \frac{P}{V} \right)^{1/4}$<br>$P/V$ = power/volume (kW/m <sup>3</sup> ), range = 100 to 10,000   | [E] Each channel in monolith is a capillary. Results are in expected order of magnitude for capillaries based on 5-21-Z.<br>$k_L$ is larger than in stirred tanks.  | [93]  |
| AB. Rising small bubbles of gas in liquid, continuous phase. Calderbank and Moo-Young correlation | $N_{Sh} = \frac{k'_c d_b}{D_c} = 2 + 0.31(N_{Gr})^{1/3} N_{Sc}^{1/3}$ , $d_b < 0.25$ cm<br>$N_{Re} = \frac{d_b^3 \rho_C - \rho_L g}{\mu_L D_L} = \text{Raleigh number}$  | [E] Use with arithmetic concentration difference. Valid for single bubbles or swarms. Independent of agitation as long as bubble size is constant. Recommended by [136].<br>Note that $N_{Re} = N_{Gr} N_{Sc}$ .  | [47][66] p. 451<br>[88] p. 119<br>[152] p. 156<br>[136] |
| AC. Same as 5-21-AB, large bubbles  | $N_{Sh} = \frac{k'_c d_b}{D_c} = 0.42(N_{Gr})^{1/3} N_{Sc}^{1/2}$ , $d_b > 0.25$ cm<br>$\frac{\text{Interfacial area}}{\text{volume}} = a = \frac{6 H_g}{d_b}$   | [E] Use with arithmetic concentration difference. For large bubbles, $k'_c$ is independent of bubble size and independent of agitation or liquid velocity. Resistance is entirely in liquid phase for most gas-liquid mass transfer.<br>$H_g$ = fractional gas holdup, volume gas/total volume.               | [47][66] p. 452<br>[88] p. 119<br>[97] p. 249<br>[136]  |
| AD. Bubbles in bubble columns. Hughmark correlation   | $N_{Sh} = \frac{k_L d}{D} = 2 + b N_{Sc}^{0.546} N_{Re}^{0.779} \left( \frac{d_g^{1/3}}{D^{2/3}} \right)^{0.116}$<br>$b = 0.061$ single gas bubbles;<br>$b = 0.0187$ swarms of bubbles,<br>$V_s = \frac{V_g}{\phi_C} - \frac{V_L}{1 - \phi_C}$ | [E] $d$ = bubble diameter<br>Air-liquid. Recommended by [136, 152]. For swarms, calculate<br>$N_{Re}$ with slip velocity $V_s$ .<br>$\phi_C$ = gas holdup<br>$V_G$ = superficial gas velocity<br>Col. diameter = 0.025 to 1.1 m<br>$\rho_L$ = 776 to 1696 kg/m <sup>3</sup><br>$\mu_L$ = 0.0009 to 0.152 Pa·s | [55]<br>[82]<br>[152] p. 144                            |
| AE. Bubbles in bubble column  | $k_L a = 0.00315 a_C^{0.59} \mu_{\text{eff}}^{-0.84}$  | [E] Recommended by [136].   | [57]  |

| AH. Three phase (gas-liquid-solid) bubble column to solid spheres | $N_{sh} = \frac{k_L d_p}{D} = 2.0 + 0.545 N_{Sc}^{1/3} \left( \frac{e d_p^4}{\nu^3} \right)^{0.264}$<br>$N_{Sc} = 137$ to 50,000 (very wide range)<br>$d_p$ = particle diameter (solids)   | [E] $e$ = local energy dissipation rate/unit mass,<br>$e = u_{gg}$<br>$N_{Sc} = \mu_L / (\rho_L D)$<br>Recommended by [136].  | [129]<br>[136] |

See Table 5-22 for agitated systems.

\*See the beginning of the "Mass Transfer" subsection for references.

practical purposes  $\hat{k}_C$  is independent of temperature and pressure in the normal ranges of these variables.

For modest changes in temperature the influence of temperature upon the interfacial area  $a$  may be neglected. For example, in experiments on the absorption of SO<sub>2</sub> in water, Whitney and Vivian [*Chem. Eng. Prog.*, **45**, 323 (1949)] found no appreciable effect of temperature upon  $k'_C a$  over the range from 10 to 50°C.

With regard to the liquid-phase mass-transfer coefficient, Whitney and Vivian found that the effect of temperature upon  $k_L a$  could be explained entirely by variations in the liquid-phase viscosity and diffusion coefficient with temperature. Similarly, the oxygen-desorption data of Sherwood and Holloway [*Trans. Am. Inst. Chem. Eng.*, **36**, 39 (1940)] show that the influence of temperature upon  $H_L$  can be explained by the effects of temperature upon the liquid-phase viscosity and diffusion coefficients (see Table 5-24-A).

It is important to recognize that the effects of temperature on the liquid-phase diffusion coefficients and viscosities can be very large and therefore must be carefully accounted for when using  $k_L$  or  $H_L$  data. For liquids the mass-transfer coefficient  $k_L$  is correlated as either the Sherwood number or the Stanton number as a function of the Reynolds and Schmidt numbers (see Table 5-24). Typically, the general form of the correlation for  $H_L$  is (Table 5-24)

$$H_L = b N_{Re}^a N_{Sc}^{1/2} \quad (5-306)$$

where  $b$  is a proportionality constant and the exponent  $a$  may range from about 0.2 to 0.5 for different packings and systems. The liquid-phase diffusion coefficients may be corrected from a base temperature  $T_1$  to another temperature  $T_2$  by using the Einstein relation as recommended by Wilke [*Chem. Eng. Prog.*, **45**, 218 (1949)]:

$$D_2 = D_1 (T_2/T_1) (\mu_1/\mu_2) \quad (5-307)$$

The Einstein relation can be rearranged to the following equation for relating Schmidt numbers at two temperatures:

$$N_{Sc2} = N_{Sc1} (T_1/T_2) (\rho_1/\rho_2) (\mu_2/\mu_1)^2 \quad (5-308)$$

Substitution of this relation into Eq. (5-306) shows that for a given geometry the effect of temperature on  $H_L$  can be estimated as

$$H_{L2} = H_{L1} (T_1/T_2)^{1/2} (\rho_1/\rho_2)^{1/2} (\mu_2/\mu_1)^{1-a} \quad (5-309)$$

In using these relations it should be noted that for equal liquid flow rates

$$H_{L2}/H_{L1} = (\hat{k}_{L1} a)/(\hat{k}_{L2} a) \quad (5-310)$$

**Effects of System Physical Properties on  $\hat{k}_C$  and  $\hat{k}_L$**  When designing packed towers for nonreacting gas-absorption systems for which no experimental data are available, it is necessary to make corrections for differences in composition between the existing test data and the system in question. The ammonia-water test data (see Table 5-24-B) can be used to estimate  $H_C$ , and the oxygen desorption data (see Table 5-24-A) can be used to estimate  $H_L$ . The method for doing this is illustrated in Table 5-24-E. There is some conflict on whether the value of the exponent for the Schmidt number is 0.5 or 2/3 [Yadav and Sharma, *Chem. Eng. Sci.* **34**, 1423 (1979)]. Despite this disagreement, this method is extremely useful, especially for absorption and stripping systems.

It should be noted that the influence of substituting solvents of widely differing viscosities upon the interfacial area  $a$  can be very large. One therefore should be cautious about extrapolating  $k_L a$  data to account for viscosity effects between different solvent systems.

**Effects of High Solute Concentrations on  $k_C$  and  $k_L$**  As discussed previously, the stagnant-film model indicates that  $k_C$  should be independent of  $y_{BM}$  and  $k_C$  should be inversely proportional to  $y_{BM}$ . The data of Vivian and Behrman [*Am. Inst. Chem. Eng. J.*, **11**, 656 (1965)] for the absorption of ammonia from an inert gas strongly suggest that the film model's predicted trend is correct. This is another indication that the most appropriate rate coefficient to use in concentrated systems is  $k_C$  and the proper driving-force term is of the form  $(y - y_i)/y_{BM}$ .

The use of the rate coefficient  $\hat{k}_L$  and the driving force  $(x_i - x)/x_{BM}$  is believed to be appropriate. For many practical situations the liquid-phase solute concentrations are low, thus making this assumption unimportant.

**Influence of Chemical Reactions on  $k_C$  and  $k_L$**  When a chemical reaction occurs, the transfer rate may be influenced by the chemical reaction as well as by the purely physical processes of diffusion and convection within the two phases. Since this situation is common in gas absorption, gas absorption will be the focus of this discussion. One must consider the impacts of chemical equilibrium and reaction kinetics on the absorption rate in addition to accounting for the effects of gas solubility, diffusivity, and system hydrodynamics.

There is no sharp dividing line between pure physical absorption and absorption controlled by the rate of a chemical reaction. Most cases fall in an intermediate range in which the rate of absorption is limited both by the resistance to diffusion and by the finite velocity of the reaction. Even in these intermediate cases the equilibria between the various diffusing species involved in the reaction may affect the rate of absorption.

TABLE 5-22 Mass-Transfer Correlations for Particles, Drops, and Bubbles in Agitated Systems

Same as 22-B, small particles</p>  | $N_{Sh} = 2 + 0.52 N_{Re,p}^{0.52} N_{Sc}^{1/3}, N_{Re,p} < 1.0$  | <p>[E] Terms same as above.</p>  | <p>[88] p. 116</p>                                   |       |        |         |        |         |  |     |      |      |      |      |       |  |   |
| <p>D. Solid particles with significant density difference</p>  | $N_{Sh} = \frac{k'_L d_p}{D} = 2 + 0.44 \left( \frac{d_p v_{slip}}{v} \right)^{1/2} N_{Sc}^{0.38}$  | <p>[E] Use log mean concentration difference. <math>N_{Sh}</math> standard deviation 11.1%. <math>v_{slip}</math> calculated by methods given in reference.</p>  | <p>[102]<br/>[110]</p>                               |       |        |         |        |         |  |     |      |      |      |      |       |  |   |
| <p>E. Small solid particles, gas bubbles or liquid drops, <math>d_p &lt; 2.5</math> mm. Aerated mixing vessels</p> | $N_{Sh} = \frac{k'_L d_p}{D} = 2 + 0.31 \left[ \frac{d_p^3  \rho_p - \rho_c }{\mu_c D} \right]^{1/3}$   | <p>[E] Use log mean concentration difference. <math>g = 9.80665</math> m/s<sup>2</sup>. Second term RHS is free-fall or rise term. For large bubbles, see Table 5-21-AC.</p>   | <p>[46][67] p. 487<br/>[97] p. 249</p>               |       |        |         |        |         |  |     |      |      |      |      |       |  |   |
| <p>F. Highly agitated systems; solid particles, drops, and bubbles; continuous phase coefficient</p>               | $k'_L N_{Sc}^{2/3} = 0.13 \left[ \frac{(PN_{tank}) \mu_c g_c}{\rho_c^2} \right]^{1/4}$  | <p>[E] Use arithmetic concentration difference. Use when gravitational forces overcome by agitation. Up to 60% deviation. Correlation prediction is low (Ref. 102). <math>(PN_{tank})</math> = power dissipated by agitator per unit volume liquid.</p>  | <p>[47]<br/>[66] p. 489<br/>[110]</p>                |       |        |         |        |         |  |     |      |      |      |      |       |  |   |
| <p>G. Liquid drops in baffled tank with flat six-blade turbine</p>   | $k'_L a = 2.621 \times 10^{-3} \frac{(ND)^{1/2}}{d_{imp}}$ $\times \phi^{0.304} \left( \frac{d_{imp}}{d_{tank}} \right)^{1.582} N_{Re}^{1.929} N_{Oh}^{1.025}$  | <p>[E] Use arithmetic concentration difference. Studied for five systems.</p> $N_{Re} = d_{imp}^2 N_{\rho_c} / \mu_c, N_{Oh} = \mu_c / (\rho_c d_{imp} \sigma)^{1/2}$ <p><math>\phi</math> = volume fraction dispersed phase. <math>N</math> = impeller speed (revolutions/time). For <math>d_{tank} = h_{tank}</math>, average absolute deviation 23.8%.</p>  | <p>[144] p. 437</p>                                  |       |        |         |        |         |  |     |      |      |      |      |       |  |   |
| <p>H. Liquid drops in baffled tank, low volume fraction dispersed phase</p>  | $N_{Sh} = \frac{k'_L d_p}{D} = 1.237 \times 10^{-5} N_{Sc}^{1/3} N^{2/3}$ $\times N_{Fr}^{5/12} \left( \frac{d_{imp}}{d_p} \right) \left( \frac{d_p}{D_{tank}} \right)^{1/2} \left( \frac{\rho_a d_p^2}{\sigma} \right)^{5/4} \phi^{-1/2}$ <p>Stainless steel flat six-blade turbine. Tank had four baffles. Correlation recommended for <math>\phi \leq 0.06</math> [Ref. 146] <math>a = 6\phi/d_{32}</math>, where <math>d_{32}</math> is Sauter mean diameter when 33% mass transfer has occurred.</p>   | <p>[E] 180 runs, 9 systems, <math>\phi = 0.01</math>. <math>k_c</math> is time-averaged. Use arithmetic concentration difference.</p> $N_{Re} = \left( \frac{d_{imp}^2 N_{Sc}}{\mu_c} \right), N_{Fr} = \left( \frac{d_{imp} N^2}{g} \right)$ <p><math>d_p</math> = particle or drop diameter; <math>\sigma</math> = interfacial tension, N/m; <math>\phi</math> = volume fraction dispersed phase; <math>a</math> = interfacial volume, 1/m; and <math>k_c \alpha D^{2/3}</math> implies rigid drops. Negligible drop coalescence. Average absolute deviation—19.71%. Graphical comparison given by Ref. 143.</p> | <p>[143] [146]<br/>p. 78</p>                         |       |        |         |        |         |  |     |      |      |      |      |       |  |   |

**5-76 HEAT AND MASS TRANSFER**

**TABLE 5-22 Mass-Transfer Correlations for Particles, Drops, and Bubbles in Agitated Systems (Concluded)**

| Situation   | Correlation   | Comments<br>E = Empirical, S = Semiempirical, T = Theoretical   | References* |
|---|---|---|-------------|
| I. Gas bubble swarms in sparged tank reactors                           | $k_L a \left( \frac{v}{g^2} \right)^{1/3} = C \left[ \frac{P/V_L}{\rho(vg^4)^{1/3}} \right]^a \left[ \frac{q_G}{V_L} \left( \frac{v}{g^2} \right)^{1/3} \right]^b$ Rushton turbines: $C = 7.94 \times 10^{-4}$ , $a = 0.62$ , $b = 0.23$ .<br>Intermig impellers: $C = 5.89 \times 10^{-4}$ , $a = 0.62$ , $b = 0.19$ .   | [E] Use arithmetic concentration difference. Done for biological system. O <sub>2</sub> transfer. $h_{\text{tank}}/D_{\text{tank}} = 2.1$ ; $P$ = power, kW. $V_L$ = liquid volume, m <sup>3</sup> . $q_G$ = gassing rate, m <sup>3</sup> /s. $k_L a = s^{-1}$ . Since $a = m^2/m^3$ , $v$ = kinematic viscosity, m <sup>2</sup> /s. Low viscosity system. Better fit claimed with $q_G/V_L$ than with $u_G$ (see 5-22-J to N).                       | [131]       |
| J. Same as 5-22-I   | $k_L a = 2.6 \times 10^{-2} \left( \frac{P}{V_L} \right)^{0.4} u_G^{0.5}$   | [E] Use arithmetic concentration difference. Ion free water $V_L < 2.6$ , $u_G$ = superficial gas velocity in m/s. $500 < P/V_L < 10,000$ . $P/V_L$ = watts/m <sup>3</sup> , $V_L$ = liquid volume, m <sup>3</sup> .  | [98] [123]  |
| K. Same as 5-22-J   | $k_L a = 2.0 \times 10^{-3} \left( \frac{P}{V_L} \right)^{0.7} u_G^{0.2}$   | [E] Use arithmetic concentration difference. Water with ions. $0.002 < V_L < 4.4$ , $500 < P/V_L < 10,000$ . Same definitions as 5-22-I.  | [98] [101]  |
| L. Same as 5-22-I, baffled tank with standard blade Rushton impeller    | $k_L a = 93.37 \left( \frac{P}{V_L} \right)^{0.76} u_G^{0.45}$  | [E] Air-water. Same definitions as 5-22-I. $0.005 < u_G < 0.025$ , $3.83 < N < 8.33$ , $400 < P/V_L < 7000$ . $h = D_{\text{tank}} = 0.305$ or $0.610$ m. $V_G$ = gas volume, m <sup>3</sup> , $N$ = stirrer speed, rpm. Method assumes perfect liquid mixing.  | [67] [98]   |
| M. Same as 5-22-L   | $k_L a \frac{d_{\text{imp}}^2}{D} = 7.57 \left[ \frac{\mu_{\text{eff}}}{\rho D} \right]^{0.57} \left[ \frac{\mu_C}{\mu_{\text{eff}}} \right]^{0.694} \times \left[ \frac{d_{\text{imp}}^2 N \rho_L}{\mu_{\text{eff}}} \right]^{1.11} \left( \frac{u_G d}{\sigma} \right)^{0.447}$ $d_{\text{imp}}$ = impeller diameter, m; $D$ = diffusivity, m <sup>2</sup> /s | [E] Use arithmetic concentration difference. CO <sub>2</sub> into aqueous carboxyl polymethylene. Same definitions as 5-22-L. $\mu_{\text{eff}}$ = effective viscosity from power law model, Pa·s. $\sigma$ = surface tension liquid, N/m.  | [98] [115]  |
| N. Same as 5-22-L, bubbles  | $\frac{k_L a d_{\text{imp}}^2}{D} = 0.060 \left( \frac{d_{\text{imp}}^2 N \rho}{\mu_{\text{eff}}} \right) \left( \frac{d_{\text{imp}}^2 N^2}{g} \right)^{0.19} \left( \frac{\mu_{\text{eff}} u_G}{\sigma} \right)^{0.6}$  | [E] Use arithmetic concentration difference. O <sub>2</sub> into aqueous glycerol solutions. O <sub>2</sub> into aqueous millet jelly solutions. Same definitions as 5-22-L.  | [98] [160]  |
| O. Gas bubble swarm in sparged stirred tank reactor with solids present | $\frac{k_L a}{(k_L a)_0} = 1 - 3.54(\epsilon_s - 0.03)$ $300 \leq P/V_{rx} < 10,000 \text{ W/m}^3$ , $0.03 \leq \epsilon_s \leq 0.12$<br>$0.34 \leq u_G \leq 4.2 \text{ cm/s}$ , $5 < \mu_L < 75 \text{ Pa}\cdot\text{s}$   | [E] Use arithmetic concentration difference. Solids are glass beads, $d_p = 320 \mu\text{m}$ . $\epsilon_s$ = solids holdup m <sup>3</sup> /m <sup>3</sup> liquid. $(k_L a)_0$ = mass transfer in absence of solids. Ionic salt solution—noncoalescing.   | [38] [132]  |
| P. Surface aerators for air-water contact                               | $\frac{k_L a}{N} = b N_p^{0.71} N_{Fr}^{0.48} N_{Re}^{0.82} \left( \frac{H}{d} \right)^{-0.54} \left( \frac{V}{d^3} \right)^{-1.08}$ $b = 7 \times 10^{-6}$ , $N_p = P/(\rho N^3 d^5)$<br>$N_{Re} = Nd^2 \rho_{\text{liq}}/\mu_{\text{liq}}$<br>$N_{Fr} = N^2 d/g$ , $P/V = 90$ to $400 \text{ W/m}^3$  | [E] Three impellers: Pitched blade downflow turbine, pitched blade upflow turbine, standard disk turbine. Baffled cylindrical tanks 1.0- and 1.5-m ID and 8.2 × 8.2-m square tank. Submergence optimized all cases. Good agreement with data. $N$ = impeller speed, s <sup>-1</sup> ; $d$ = impeller diameter, m; $H$ = liquid height, m; $V$ = liquid volume, m <sup>3</sup> ; $k_L a = s^{-1}$ , $g$ = acceleration gravity = 9.81 m/s <sup>2</sup> | [113]       |
| Q. Gas-inducing impeller for air-water contact                          | $k_L a V (v/g^2)^{1/3} d^3 = AN_{Fr}^B \left( \frac{V_A}{V} \right)^C$ Single impeller:<br>$A = 0.00497$ , $B = 0.56$ , $C = 0.32$<br>Multiple impeller:<br>$A = 0.00746$ , $B = 0.54$ , $C = 0.38$   | [E] Same tanks and same definitions as in 5-22-P. $V_A$ = active volume = $p/(\pi \rho g N d)$ .  | [113]       |
| R. Gas-inducing impeller with dense solids                              | $Sh_{GL} = \frac{k_L a d_{st}^2}{D} = (1.26 \times 10^{-5}) N_{Re}^{1.8} N_{Sc}^{0.9} N_{We}^{-0.1}$ $N_{Re} = \rho N d_{st}^2 \mu$ , $N_{Sc} = \mu/(\rho D)$ ,<br>$N_{We} = \rho N^2 d_{st}^3 / \sigma$  | [E] Hydrogenation with Raney-type nickel catalyst in stirred autoclave. Used varying $T$ , $p$ , solvents. $d_{st}$ = stirrer diameter.   | [78]        |

TABLE 5-23 Mass Transfer Correlations for Fixed and Fluidized Beds (Continued)

| Situation  | Correlation   | Comments<br>E = Empirical, S = Semiempirical, T = Theoretical  | References°                            |
|--|---|--|--|
| G. Electrolytic system. Pall rings.<br>Transfer from fluid to rings.                 | Full liquid upflow:<br>$N_{sh} = k_L d_p / D = 4.1 N_{Re}^{0.39} N_{Sc}^{1/3}$<br>$N_{Re} d_p u / \nu = 80$ to 550<br>Irrigated liquid downflow (no gas flow):<br>$N_{Sh} = 5.1 N_{Re}^{0.44} N_{Sc}^{1/3}$                               | [E] $d_c$ = diameter of sphere with same surface area as Pall ring. Full liquid upflow agreed with literature values. Schmidt number dependence was assumed from literature values. In downflow, $N_{Re}$ used superficial fluid velocity. | [69]                                   |
| H. For liquids, fixed and fluidized beds   | $\epsilon j_D = \frac{1.1068}{N_{Re}^{0.72}}, 1.0 < N_{Re} \leq 10$<br>$\epsilon j_D = \frac{N_{Sh}}{N_{Re} N_{Sc}^{1/3}}, N_{Sh} = \frac{k' d_s}{D}$   | [E] Spheres:<br>$N_{Re} = \frac{d_p v_{super} \rho}{\mu}$  | [59][66]<br>p. 484                     |
| I. For gases and liquids, fixed and fluidized beds, Dwivedi and Upadhyay correlation | $\epsilon j_D = \frac{0.765}{N_{Re}^{0.82}} + \frac{0.365}{N_{Re}^{0.386}}$<br>Gases: $10 \leq N_{Re} \leq 15,000$ .<br>Liquids: $0.01 \leq N_{Re} \leq 15,000$ .<br>$N_{Re} = \frac{d_p v_{super} \rho}{\mu}, N_{Sh} = \frac{k' d_s}{D}$ | [E] Deep beds of spheres,<br>$j_D = \frac{N_{Sh}}{N_{Re} N_{Sc}^{1/3}}$<br>Best fit correlation at low conc. [52]<br>Based on 20 gas studies and 17 liquid studies.<br>Recommended instead of 5-23-C or E.                                 | [59] [77]<br>p. 196<br>[52]            |
| J. For gases and liquids, fixed bed  | $j_D = 1.17 N_{Re}^{-0.415}, 10 \leq N_{Re} \leq 2500$<br>$j_D = \frac{k'}{v_{av}} \frac{p_{BM}}{P} N_{Sc}^{2/3}$   | [E] Spheres: Variation in packing that changes $\epsilon$ not allowed for. Extensive data referenced. $0.5 < N_{Sc} < 15,000$ . Comparison with other results are shown.<br>$N_{Re} = \frac{d_p v_{super} \rho}{\mu}$                      | [138] p. 241                           |
| K. For liquids, fixed and fluidized beds, Rahman and Streat correlation              | $N_{Sh} = \frac{0.86}{\epsilon} N_{Re}^{1/3} N_{Sc}^{1/3}, 2 \leq N_{Re} \leq 25$   | [E] Can be extrapolated to $N_{Re} = 2000$ . $N_{Re} = d_p v_{super} \rho / \mu$ . Done for neutralization of ion exchange resin.  | [119]                                  |
| L. Size exclusion chromatography of proteins   | $N_{Sh} = \frac{k_L d}{D} = \frac{1.903}{\epsilon} N_{Re}^{1/3} N_{Sc}^{1/3}$   | [E] Slow mass transfer with large molecules. Aqueous solutions. Modest increase in $N_{Sh}$ with increasing velocity.  | [79]                                   |
| M. Liquid-free convection with fixed bed Raschig rings. Electrochemical.             | $N_{Sh} = kd/D = 0.15 (N_{Sc} N_{Gr})^{0.32}$<br>$N_{Gr} = \text{Grashof no.} = gd^3 \Delta \rho / (\nu^2 \rho)$<br>If forced convection superimposed,<br>$N_{Sh, overall} = (N_{Sh, forced}^3 + N_{Sh, free}^3)^{1/3}$                   | [E] $d$ = Raschig ring diameter, $h$ = bed height<br>$1810 < N_{Sc} < 2532, 0.17 < d/h < 1.0$<br>$10.6 \times 10^6 < N_{Sc} N_{Gr} < 21 \times 10^7$   | [135]                                  |
| N. Oscillating bed packed with Raschig rings. Dissolution of copper rings.           | Batch (no net solution flow):<br>$N_{Sh} = 0.76 N_{Re}^{0.33} N_{Sc}^{0.7} (d_c/h)^{0.35}$<br>$503 < N_{Re,v} < 2892$<br>$960 < N_{Sc} < 1364, 2.3 < d_c/h < 7.6$   | [E] $N_{Sh} = kd_c/D, N_{Re,v} = \text{vibrational Re} = \rho v_c d_c / \mu$<br>$v_c = \text{vibrational velocity (intensity)}$<br>$d_c = \text{col. diameter, } h = \text{column height}$<br>Average deviation is $\pm 12\%$ .            | [61]                                   |
| O. For liquids and gases, Ranz and Marshall correlation                              | $N_{Sh} = \frac{k' d}{D} = 2.0 + 0.6 N_{Sc}^{1/3} N_{Re}^{1/2}$<br>$N_{Re} = \frac{d_p v_{super} \rho}{\mu}$  | [E] Based on freely falling, evaporating spheres (see 5-20-C). Has been applied to packed beds, prediction is low compared to experimental data. Limit of 2.0 at low $N_{Re}$ is too high. Not corrected for axial dispersion.             | [121][128]<br>p. 214<br>[155]<br>[110] |
| P. For liquids and gases, Wakao and Funazkri correlation                             | $N_{Sh} = 2.0 + 1.1 N_{Sc}^{1/3} N_{Re}^{0.6}, 3 < N_{Re} < 10,000$<br>$N_{Sh} = \frac{k'_{lim} d_p}{D}, N_{Re} = \frac{\rho r v_{super} \rho}{\mu}$<br>$\frac{\epsilon D_{axial}}{D} = 10 + 0.5 N_{Sc} N_{Re}$                           | [E] Correlate 20 gas studies and 16 liquid studies. Corrected for axial dispersion with: Graphical comparison with data shown [128], p. 215, and [155].<br>$D_{axial}$ is axial dispersion coefficient.                                    | [128] p. 214<br>[155]                  |
| Q. Acid dissolution of limestone in fixed bed  | $N_{Sh} = 1.77 N_{Re}^{0.56} N_{Sc}^{1/3} (1 - \epsilon)^{0.44}$<br>$20 < N_{Re} < 6000$  | [E] Best fit was to correlation of Chu et al., <i>Chem. Eng. Prog.</i> , <b>49</b> (3), 141(1953), even though no reaction in original.  | [94]                                   |
| R. Semifluidized or expanded bed. Liquid-solid transfer.                             | $N_{Sh} = \frac{k'_{lim} d_p}{D} = 2 + 1.5 (1 - \epsilon_L) N_{Re}^{1/3} N_{Sc}^{1/3}$<br>$N_{Re} = \rho_p d_p u / \mu \epsilon_L, N_{Sc} = \mu / \rho D$   | [E] $\epsilon_L$ = liquid-phase void fraction, $\rho_p$ = particle density, $\rho$ = fluid density, $d_p$ = particle diameter. Fits expanded bed chromatography in viscous liquids.  | [64]<br>[159]                          |

TABLE 5-23 Mass Transfer Correlations for Fixed and Fluidized Beds (Concluded)

| Situation  | Correlation   | Comments<br>E = Empirical, S = Semiempirical, T = Theoretical   | References <sup>o</sup> |
|--|---|---|-------------------------|
| S. Mass-transfer structured packing and static mixers. Liquid with or without fluidized particles. See also Sec. 14.  
°See the beginning of the “Mass Transfer” subsection for references.

The gas-phase rate coefficient  $\hat{k}_C$  is not affected by the fact that a chemical reaction is taking place in the liquid phase. If the liquid-phase chemical reaction is extremely fast and irreversible, the rate of absorption may be governed completely by the resistance to diffusion in the gas phase. In this case the absorption rate may be estimated by

knowing only the gas-phase rate coefficient  $\hat{k}_C$  or else the height of one gas-phase transfer unit  $H_G = G_M/(\hat{k}_C a)$ .  
It should be noted that the highest possible absorption rates will occur under conditions in which the liquid-phase resistance is negligible and the equilibrium back pressure of the gas over the solvent is zero.

Such situations would exist, for instance, for  $\text{NH}_3$  absorption into an acid solution, for  $\text{SO}_2$  absorption into an alkali solution, for vaporization of water into air, and for  $\text{H}_2\text{S}$  absorption from a dilute-gas stream into a strong alkali solution, provided there is a large excess of reagent in solution to consume all the dissolved gas. This is known as the gas-phase mass-transfer limited condition, when both the liquid-phase resistance and the back pressure of the gas equal zero. Even when the reaction is sufficiently reversible to allow a small back pressure, the absorption may be gas-phase-controlled, and the values of  $\hat{k}_G$  and  $H_G$  that would apply to a physical-absorption process will govern the rate.

The liquid-phase rate coefficient  $k_L$  is strongly affected by fast chemical reactions and generally increases with increasing reaction rate. Indeed, the condition for zero liquid-phase resistance ( $m\hat{k}_L$ ) implies that either the equilibrium back pressure is negligible, or that  $\hat{k}_L$  is very large, or both. Frequently, even though reaction consumes the solute as it is dissolving, thereby enhancing both the mass-transfer coefficient and the driving force for absorption, the reaction rate is slow enough that the liquid-phase resistance must be taken into account. This may be due either to an insufficient supply of a second reagent or to an inherently slow chemical reaction.

In any event the value of  $\hat{k}_L$  in the presence of a chemical reaction normally is larger than the value found when only physical absorption occurs,  $\hat{k}_L^0$ . This has led to the presentation of data on the effects of chemical reaction in terms of the "reaction factor" or "enhancement factor" defined as

$$\phi = \hat{k}_L / \hat{k}_L^0 \geq 1 \quad (5-311)$$

where  $\hat{k}_L$  = mass-transfer coefficient with reaction and  $\hat{k}_L^0$  = mass-transfer coefficient for pure physical absorption.

It is important to understand that when chemical reactions are involved, this definition of  $\hat{k}_L$  is based on the driving force defined as the difference between the concentration of *unreacted* solute gas at the interface and in the bulk of the liquid. A coefficient based on the total of both unreacted and reacted gas could have values *smaller* than the physical-absorption mass-transfer coefficient  $\hat{k}_L^0$ .

When liquid-phase resistance is important, particular care should be taken in employing any given set of experimental data to ensure that the equilibrium data used conform with those employed by the original author in calculating values of  $\hat{k}_L$  or  $H_L$ . Extrapolation to widely different concentration ranges or operating conditions should be made with caution, since the mass-transfer coefficient  $\hat{k}_L$  may vary in an unexpected fashion, owing to changes in the apparent chemical-reaction mechanism.

Generalized prediction methods for  $\hat{k}_L$  and  $H_L$  do not apply when chemical reaction occurs in the liquid phase, and therefore one must use actual operating data for the particular system in question. A discussion of the various factors to consider in designing gas absorbers and strippers when chemical reactions are involved is presented by Astarita, Savage, and Bisio, *Gas Treating with Chemical Solvents*, Wiley (1983) and by Kohl and Nielsen, *Gas Purification*, 5th ed., Gulf (1997).

**Effective Interfacial Mass-Transfer Area  $a$**  In a packed tower of constant cross-sectional area  $S$  the differential change in solute flow per unit time is given by

$$-d(G_M S y) = N_A a dV = N_A a S dh \quad (5-312)$$

where  $a$  = interfacial area effective for mass transfer per unit of packed volume and  $V$  = packed volume. Owing to incomplete wetting of the packing surfaces and to the formation of areas of stagnation in the liquid film, the effective area normally is significantly less than the total external area of the packing pieces.

The effective interfacial area depends on a number of factors, as discussed in a review by Charpentier [*Chem. Eng. J.*, **11**, 161 (1976)]. Among these factors are (1) the shape and size of packing, (2) the packing material (for example, plastic generally gives smaller interfacial areas than either metal or ceramic), (3) the liquid mass velocity, and (4), for small-diameter towers, the column diameter.

Whereas the interfacial area generally increases with increasing liquid rate, it apparently is relatively independent of the superficial gas mass velocity below the flooding point. According to Charpentier's review, it appears valid to assume that the interfacial area is independent of the column height when specified in terms of unit packed volume (i.e., as  $a$ ). Also, the existing data for chemically reacting gas-liquid systems (mostly aqueous electrolyte solutions) indicate that

the interfacial area is independent of the chemical system. However, this situation may not hold true for systems involving large heats of reaction.

Rizzuti et al. [*Chem. Eng. Sci.*, **36**, 973 (1981)] examined the influence of solvent viscosity upon the effective interfacial area in packed columns and concluded that for the systems studied the effective interfacial area  $a$  was proportional to the kinematic viscosity raised to the 0.7 power. Thus, the hydrodynamic behavior of a packed absorber is strongly affected by viscosity effects. Surface-tension effects also are important, as expressed in the work of Onda et al. (see Table 5-24-C).

In developing correlations for the mass-transfer coefficients  $\hat{k}_G$  and  $\hat{k}_L$ , the various authors have assumed different but internally compatible correlations for the effective interfacial area  $a$ . It therefore would be inappropriate to mix the correlations of different authors unless it has been demonstrated that there is a valid area of overlap between them.

**Volumetric Mass-Transfer Coefficients  $\hat{K}_G a$  and  $\hat{K}_L a$**  Experimental determinations of the individual mass-transfer coefficients  $\hat{k}_G$  and  $\hat{k}_L$  and of the effective interfacial area  $a$  involve the use of extremely difficult techniques, and therefore such data are not plentiful. More often, column experimental data are reported in terms of overall volumetric coefficients, which normally are defined as follows:

$$K'_{G a} = n_A / (h_T S p_T \Delta y_{1m}^0) \quad (5-313)$$

$$\text{and} \quad K_{L a} = n_A / (h_T S \Delta x_{1m}^0) \quad (5-314)$$

where  $K'_{G a}$  = overall volumetric gas-phase mass-transfer coefficient,  $K_{L a}$  = overall volumetric liquid-phase mass-transfer coefficient,  $n_A$  = overall rate of transfer of solute  $A$ ,  $h_T$  = total packed depth in tower,  $S$  = tower cross-sectional area,  $p_T$  = total system pressure employed during the experiment, and  $\Delta x_{1m}^0$  and  $\Delta y_{1m}^0$  are defined as

$$\Delta y_{1m}^0 = \frac{(y - y^0)_1 - (y - y^0)_2}{\ln [(y - y^0)_1 / (y - y^0)_2]} \quad (5-315)$$

$$\text{and} \quad \Delta x_{1m}^0 = \frac{(x^0 - x)_2 - (x^0 - x)_1}{\ln [(x^0 - x)_2 / (x^0 - x)_1]} \quad (5-316)$$

where subscripts 1 and 2 refer to the bottom and top of the tower respectively.

Experimental  $K'_{G a}$  and  $K_{L a}$  data are available for most absorption and stripping operations of commercial interest (see Sec. 14). The solute concentrations employed in these experiments normally are very low, so that  $K_{L a} \approx \hat{K}_{L a}$  and  $K'_{G a} p_T \approx \hat{K}'_{G a}$ , where  $p_T$  is the total pressure employed in the actual experimental-test system. Unlike the individual gas-film coefficient  $\hat{k}_G a$ , the overall coefficient  $\hat{K}'_{G a}$  will vary with the total system pressure except when the liquid-phase resistance is negligible (i.e., when either  $m = 0$ , or  $\hat{k}_L a$  is very large, or both).

Extrapolation of  $K'_{G a}$  data for absorption and stripping to conditions other than those for which the original measurements were made can be extremely risky, especially in systems involving chemical reactions in the liquid phase. One therefore would be wise to restrict the use of overall volumetric mass-transfer-coefficient data to conditions not too far removed from those employed in the actual tests. The most reliable data for this purpose would be those obtained from an operating commercial unit of similar design.

Experimental values of  $H_{OG}$  and  $H_{OL}$  for a number of distillation systems of commercial interest are also readily available. Extrapolation of the data or the correlations to conditions that differ significantly from those used for the original experiments is risky. For example, pressure has a major effect on vapor density and thus can affect the hydrodynamics significantly. Changes in flow patterns affect both mass-transfer coefficients and interfacial area.

**Chilton-Colburn Analogy** On occasion one will find that heat-transfer-rate data are available for a system in which mass-transfer-rate data are not readily available. The Chilton-Colburn analogy [90, 53] (see Tables 5-17-G and 5-19-T) provides a procedure for developing estimates of the mass-transfer rates based on heat-transfer data. Extrapolation of experimental  $j_M$  or  $j_H$  data obtained with gases to predict liquid systems (and vice versa) should be approached with caution, however. When pressure-drop or friction-factor data are available, one may be able to place an upper bound on the rates of heat and mass transfer of  $f/2$ . The Chilton-Colburn analogy can be used for simultaneous heat and mass transfer as long as the concentration and temperature fields are independent [Venkatesan and Fogler, *AIChE J.*, **50**, 1623 (2004)].

| Liquid Drops in Gases .....        | 6-55 |
| Wall Effects .....                 | 6-56 |

## Nomenclature and Units\*

In this listing, symbols used in this section are defined in a general way and appropriate SI units are given. Specific definitions, as denoted by subscripts, are stated at the place of application in the section. Some specialized symbols used in the section are defined only at the place of application. Some symbols have more than one definition; the appropriate one is identified at the place of application.

| Symbol      | Definition                             | SI units                   | U.S. customary units         | Symbol         | Definition                              | SI units               | U.S. customary units           |
|-------------|--|----------------------------|------------------------------|----------------|---|------------------------|--------------------------------|
| $a$         | Pressure wave velocity                 | m/s                        | ft/s                         | $s$            | Entropy per unit mass                   | J/(kg · K)             | Btu/(lbm · R)                  |
| $A$         | Area                                   | m <sup>2</sup>             | ft <sup>2</sup>              | $S$            | Slope                                   | Dimensionless          | Dimensionless                  |
| $b$         | Wall thickness                         | m                          | in                           | $S$            | Pumping speed                           | m <sup>3</sup> /s      | ft <sup>3</sup> /s             |
| $b$         | Channel width                          | m                          | ft                           | $S$            | Surface area per unit volume            | 1/m                    | 1/ft                           |
| $c$         | Acoustic velocity                      | m/s                        | ft/s                         | St             | Strouhal number                         | Dimensionless          | Dimensionless                  |
| $c_f$       | Friction coefficient                   | Dimensionless              | Dimensionless                | $t$            | Time                                    | s                      | s                              |
| $C$         | Conductance                            | m <sup>3</sup> /s          | ft <sup>3</sup> /s           | $t$            | Force per unit area                     | Pa                     | lbf/in <sup>2</sup>            |
| $Ca$        | Capillary number                       | Dimensionless              | Dimensionless                | $T$            | Absolute temperature                    | K                      | R                              |
| $C_0$       | Discharge coefficient                  | Dimensionless              | Dimensionless                | $u$            | Internal energy per unit mass           | J/kg                   | Btu/lbm                        |
| $C_D$       | Drag coefficient                       | Dimensionless              | Dimensionless                | $u$            | Velocity                                | m/s                    | ft/s                           |
| $d$         | Diameter                               | m                          | ft                           | $U$            | Velocity                                | m/s                    | ft/s                           |
| $D$         | Diameter                               | m                          | ft                           | $v$            | Velocity                                | m/s                    | ft/s                           |
| $De$        | Dean number                            | Dimensionless              | Dimensionless                | $V$            | Velocity                                | m/s                    | ft/s                           |
| $D_{ij}$    | Deformation rate tensor components     | 1/s                        | 1/s                          | $V$            | Volume                                  | m <sup>3</sup>         | ft <sup>3</sup>                |
| $E$         | Elastic modulus                        | Pa                         | lbf/in <sup>2</sup>          | We             | Weber number                            | Dimensionless          | Dimensionless                  |
| $\dot{E}_v$ | Energy dissipation rate                | J/s                        | ft · lbf/s                   | $\dot{W}_s$    | Rate of shaft work                      | J/s                    | Btu/s                          |
| $Eo$        | Eotvos number                          | Dimensionless              | Dimensionless                | $\delta W_s$   | Shaft work per unit mass                | J/kg                   | Btu/lbm                        |
| $f$         | Fanning friction factor                | Dimensionless              | Dimensionless                | $x$            | Cartesian coordinate                    | m                      | ft                             |
| $f$         | Vortex shedding frequency              | 1/s                        | 1/s                          | $y$            | Cartesian coordinate                    | m                      | ft                             |

## NATURE OF FLUIDS

**Deformation and Stress** A fluid is a substance which undergoes continuous deformation when subjected to a shear stress. Figure 6-1 illustrates this concept. A fluid is bounded by two large parallel plates, of area  $A$ , separated by a small distance  $H$ . The bottom plate is held fixed. Application of a force  $F$  to the upper plate causes it to move at a velocity  $U$ . The fluid continues to deform as long as the force is applied, unlike a solid, which would undergo only a finite deformation.

The force is directly proportional to the area of the plate; the shear stress is  $\tau = F/A$ . Within the fluid, a linear velocity profile  $u = Uy/H$  is established; due to the **no-slip condition**, the fluid bounding the lower plate has zero velocity and the fluid bounding the upper plate moves at the plate velocity  $U$ . The velocity gradient  $\dot{\gamma} = du/dy$  is called the **shear rate** for this flow. Shear rates are usually reported in units of reciprocal seconds. The flow in Fig. 6-1 is a **simple shear flow**.

**Viscosity** The ratio of shear stress to shear rate is the viscosity,  $\mu$ .

$$\mu = \frac{\tau}{\dot{\gamma}} \quad (6-1)$$

The SI units of viscosity are  $\text{kg}/(\text{m} \cdot \text{s})$  or  $\text{Pa} \cdot \text{s}$  (pascal second). The cgs unit for viscosity is the poise;  $1 \text{ Pa} \cdot \text{s}$  equals 10 poise or 1000 centipoise (cP) or 0.672  $\text{lbm}/(\text{ft} \cdot \text{s})$ . The terms *absolute viscosity* and *shear viscosity* are synonymous with the viscosity as used in Eq. (6-1).

**Kinematic viscosity**  $\nu \equiv \mu/\rho$  is the ratio of viscosity to density. The SI units of kinematic viscosity are  $\text{m}^2/\text{s}$ . The cgs stoke is  $1 \text{ cm}^2/\text{s}$ .

**Rheology** In general, fluid flow patterns are more complex than the one shown in Fig. 6-1, as is the relationship between fluid deformation and stress. Rheology is the discipline of fluid mechanics which studies this relationship. One goal of rheology is to obtain **constitutive equations** by which stresses may be computed from deformation rates. For simplicity, fluids may be classified into rheological types in reference to the simple shear flow of Fig. 6-1. Complete definitions require extension to multidimensional flow. For more information, several good references are available, including Bird, Armstrong, and Hassager (*Dynamics of Polymeric Liquids*, vol. 1: *Fluid Mechanics*, Wiley, New York, 1977); Metzner ("Flow of Non-Newtonian Fluids" in Streeter, *Handbook of Fluid Dynamics*, McGraw-Hill, New York, 1971); and Skelland (*Non-Newtonian Flow and Heat Transfer*, Wiley, New York, 1967).

FIG. 6-1 Deformation of a fluid subjected to a shear stress.

Fluids without any solidlike elastic behavior do not undergo any reverse deformation when shear stress is removed, and are called **purely viscous fluids**. The shear stress depends only on the rate of deformation, and not on the extent of deformation (strain). Those which exhibit both viscous and elastic properties are called **viscoelastic fluids**.

Purely viscous fluids are further classified into time-independent and time-dependent fluids. For time-independent fluids, the shear stress depends only on the instantaneous shear rate. The shear stress for time-dependent fluids depends on the past history of the rate of deformation, as a result of structure or orientation buildup or breakdown during deformation.

A **rheogram** is a plot of shear stress versus shear rate for a fluid in simple shear flow, such as that in Fig. 6-1. Rheograms for several types of time-independent fluids are shown in Fig. 6-2. The **Newtonian fluid rheogram** is a straight line passing through the origin. The slope of the line is the viscosity. For a Newtonian fluid, the viscosity is independent of shear rate, and may depend only on temperature and perhaps pressure. By far, the Newtonian fluid is the largest class of fluid of engineering importance. Gases and low molecular weight liquids are generally Newtonian. Newton's law of viscosity is a rearrangement of Eq. (6-1) in which the viscosity is a constant:

$$\tau = \mu \dot{\gamma} = \mu \frac{du}{dy} \quad (6-2)$$

All fluids for which the viscosity varies with shear rate are **non-Newtonian fluids**. For non-Newtonian fluids the viscosity, defined as the ratio of shear stress to shear rate, is often called the **apparent viscosity** to emphasize the distinction from Newtonian behavior. Purely viscous, time-independent fluids, for which the apparent viscosity may be expressed as a function of shear rate, are called **generalized Newtonian fluids**.

Non-Newtonian fluids include those for which a finite stress  $\tau_y$  is required before continuous deformation occurs; these are called **yield-stress materials**. The **Bingham plastic fluid** is the simplest yield-stress material; its rheogram has a constant slope  $\mu_\infty$ , called the *infinite shear viscosity*.

$$\tau = \tau_y + \mu_\infty \dot{\gamma} \quad (6-3)$$

Highly concentrated suspensions of fine solid particles frequently exhibit Bingham plastic behavior.

**Shear-thinning fluids** are those for which the slope of the rheogram decreases with increasing shear rate. These fluids have also been called *pseudoplastic*, but this terminology is outdated and discouraged. Many polymer melts and solutions, as well as some solids suspensions, are shear-thinning. Shear-thinning fluids without yield stresses typically obey a power law model over a range of shear rates.

$$\tau = K \dot{\gamma}^n \quad (6-4)$$

The apparent viscosity is

$$\mu = K \dot{\gamma}^{n-1} \quad (6-5)$$

FIG. 6-2 Shear diagrams.

The factor  $K$  is the consistency index or power law coefficient, and  $n$  is the power law exponent. The exponent  $n$  is dimensionless, while  $K$  is in units of  $\text{kg}/(\text{m} \cdot \text{s}^{2-n})$ . For shear-thinning fluids,  $n < 1$ . The power law model typically provides a good fit to data over a range of one to two orders of magnitude in shear rate; behavior at very low and very high shear rates is often Newtonian. Shear-thinning power law fluids with yield stresses are sometimes called *Herschel-Bulkley fluids*. Numerous other rheological model equations for shear-thinning fluids are in common use.

**Dilatant**, or shear-thickening, fluids show increasing viscosity with increasing shear rate. Over a limited range of shear rate, they may be described by the power law model with  $n > 1$ . Dilatancy is rare, observed only in certain concentration ranges in some particle suspensions (Govier and Aziz, pp. 33–34). Extensive discussions of dilatant suspensions, together with a listing of dilatant systems, are given by Green and Grisley (*Trans. Soc. Rheol.*, **12**[1], 13–25 [1968]); Grisley and Green (*AIChE J.*, **17**, 725–728 [1971]); and Bauer and Collins (“Thixotropy and Dilatancy,” in Eirich, *Rheology*, vol. 4, Academic, New York, 1967).

**Time-dependent** fluids are those for which structural rearrangements occur during deformation at a rate too slow to maintain equilibrium configurations. As a result, shear stress changes with duration of shear. **Thixotropic** fluids, such as mayonnaise, clay suspensions used as drilling muds, and some paints and inks, show decreasing shear stress with time at constant shear rate. A detailed description of thixotropic behavior and a list of thixotropic systems is found in Bauer and Collins (*ibid.*).

**Rheopeptic** behavior is the opposite of thixotropy. Shear stress increases with time at constant shear rate. Rheopeptic behavior has been observed in bentonite sols, vanadium pentoxide sols, and gypsum suspensions in water (Bauer and Collins, *ibid.*) as well as in some polyester solutions (Steg and Katz, *J. Appl. Polym. Sci.*, **9**, 3, 177 [1965]).

**Viscoelastic** fluids exhibit elastic recovery from deformation when stress is removed. Polymeric liquids comprise the largest group of fluids in this class. A property of viscoelastic fluids is the *relaxation time*, which is a measure of the time required for elastic effects to decay. Viscoelastic effects may be important with sudden changes in rates of deformation, as in flow startup and stop, rapidly oscillating flows, or as a fluid passes through sudden expansions or contractions where accelerations occur. In many fully developed flows where such effects are absent, viscoelastic fluids behave as if they were purely viscous. In viscoelastic flows, normal stresses perpendicular to the direction of shear are different from those in the parallel direction. These give rise to such behaviors as the *Weissenberg effect*, in which fluid climbs up a shaft rotating in the fluid, and *die swell*, where a stream of fluid issuing from a tube may expand to two or more times the tube diameter.

A parameter indicating whether viscoelastic effects are important is the **Deborah number**, which is the ratio of the characteristic relaxation time of the fluid to the characteristic time scale of the flow. For small Deborah numbers, the relaxation is fast compared to the characteristic time of the flow, and the fluid behavior is purely viscous. For very large Deborah numbers, the behavior closely resembles that of an elastic solid.

Analysis of viscoelastic flows is very difficult. Simple constitutive equations are unable to describe all the material behavior exhibited by viscoelastic fluids even in geometrically simple flows. More complex constitutive equations may be more accurate, but become exceedingly difficult to apply, especially for complex geometries, even with advanced numerical methods. For good discussions of viscoelastic fluid behavior, including various types of constitutive equations, see Bird, Armstrong, and Hassager (*Dynamics of Polymeric Liquids*, vol. 1: *Fluid Mechanics*, vol. 2: *Kinetic Theory*, Wiley, New York, 1977); Middleman (*The Flow of High Polymers*, Interscience (Wiley) New York, 1968); or Astarita and Marrucci (*Principles of Non-Newtonian Fluid Mechanics*, McGraw-Hill, New York, 1974).

**Polymer processing** is the field which depends most on the flow of non-Newtonian fluids. Several excellent texts are available, including Middleman (*Fundamentals of Polymer Processing*, McGraw-Hill, New York, 1977) and Tadmor and Gogos (*Principles of Polymer Processing*, Wiley, New York, 1979).

There is a wide variety of instruments for measurement of Newtonian viscosity, as well as rheological properties of non-Newtonian fluids. They are described in Van Wazer, Lyons, Kim, and Colwell (*Viscosity and Flow Measurement*, Interscience, New York, 1963); Coleman, Markowitz, and Noll (*Viscometric Flows of Non-Newtonian Fluids*, Springer-Verlag, Berlin, 1966); Dealy and Wissbrun (*Melt Rheology and Its Role in Plastics Processing*, Van Nostrand Reinhold, 1990). Measurement of rheological behavior requires well-characterized flows. Such *rheometric* flows are thoroughly discussed by Astarita and Marrucci (*Principles of Non-Newtonian Fluid Mechanics*, McGraw-Hill, New York, 1974).

## KINEMATICS OF FLUID FLOW

**Velocity** The term *kinematics* refers to the quantitative description of fluid motion or deformation. The rate of deformation depends on the distribution of velocity within the fluid. Fluid velocity  $\mathbf{v}$  is a vector quantity, with three cartesian components  $v_x$ ,  $v_y$ , and  $v_z$ . The velocity vector is a function of spatial position and time. A **steady** flow is one in which the velocity is independent of time, while in **unsteady** flow  $\mathbf{v}$  varies with time.

**Compressible and Incompressible Flow** An incompressible flow is one in which the density of the fluid is constant or nearly constant. Liquid flows are normally treated as incompressible, except in the context of hydraulic transients (see following). Compressible fluids, such as gases, may undergo incompressible flow if pressure and/or temperature changes are small enough to render density changes insignificant. Frequently, compressible flows are regarded as flows in which the density varies by more than 5 to 10 percent.

**Streamlines, Pathlines, and Streaklines** These are curves in a flow field which provide insight into the flow pattern. *Streamlines* are tangent at every point to the local instantaneous velocity vector. A *pathline* is the path followed by a material element of fluid; it coincides with a streamline if the flow is steady. In unsteady flow the pathlines generally do not coincide with streamlines. *Streaklines* are curves on which are found all the material particles which passed through a particular point in space at some earlier time. For example, a streakline is revealed by releasing smoke or dye at a point in a flow field. For steady flows, streamlines, pathlines, and streaklines are indistinguishable. In two-dimensional incompressible flows, streamlines are contours of the **stream function**.

**One-dimensional Flow** Many flows of great practical importance, such as those in pipes and channels, are treated as one-dimensional flows. There is a single direction called the *flow direction*; velocity components perpendicular to this direction are either zero or considered unimportant. Variations of quantities such as velocity, pressure, density, and temperature are considered only in the flow direction. The fundamental conservation equations of fluid mechanics are greatly simplified for one-dimensional flows. A broader category of one-dimensional flow is one where there is only one nonzero velocity component, which depends on only one coordinate direction, and this coordinate direction may or may not be the same as the flow direction.

**Rate of Deformation Tensor** For general three-dimensional flows, where all three velocity components may be important and may vary in all three coordinate directions, the concept of deformation previously introduced must be generalized. The rate of deformation tensor  $D_{ij}$  has nine components. In Cartesian coordinates,

$$D_{ij} = \left( \frac{\partial v_i}{\partial x_j} + \frac{\partial v_j}{\partial x_i} \right) \quad (6-6)$$

where the subscripts  $i$  and  $j$  refer to the three coordinate directions. Some authors define the deformation rate tensor as one-half of that given by Eq. (6-6).

**Vorticity** The relative motion between two points in a fluid can be decomposed into three components: rotation, dilatation, and deformation. The rate of deformation tensor has been defined. Dilatation refers to the volumetric expansion or compression of the fluid, and vanishes for incompressible flow. Rotation is described by a tensor  $\omega_{ij} = \partial v_i / \partial x_j - \partial v_j / \partial x_i$ . The vector of vorticity given by one-half the

## 6-6 FLUID AND PARTICLE DYNAMICS

curl of the velocity vector is another measure of rotation. In two-dimensional flow in the  $x$ - $y$  plane, the vorticity  $\omega$  is given by

$$\omega = \frac{1}{2} \left( \frac{\partial v_y}{\partial x} - \frac{\partial v_x}{\partial y} \right) \quad (6-7)$$

Here  $\omega$  is the magnitude of the vorticity vector, which is directed along the  $z$  axis. An **irrotational** flow is one with zero vorticity. Irrotational flows have been widely studied because of their useful mathematical properties and applicability to flow regions where viscous effects may be neglected. Such flows without viscous effects are called **inviscid** flows.

**Laminar and Turbulent Flow, Reynolds Number** These terms refer to two distinct types of flow. In *laminar flow*, there are smooth streamlines and the fluid velocity components vary smoothly with position, and with time if the flow is unsteady. The flow described in reference to Fig. 6-1 is laminar. In *turbulent flow*, there are no smooth streamlines, and the velocity shows chaotic fluctuations in time and space. Velocities in turbulent flow may be reported as the sum of a time-averaged velocity and a velocity fluctuation from the average. For any given flow geometry, a dimensionless **Reynolds number** may be defined for a Newtonian fluid as  $Re = LU\rho/\mu$  where  $L$  is a characteristic length. Below a critical value of  $Re$  the flow is laminar, while above the critical value a transition to turbulent flow occurs. The geometry-dependent critical Reynolds number is determined experimentally.

### CONSERVATION EQUATIONS

**Macroscopic and Microscopic Balances** Three postulates, regarded as laws of physics, are fundamental in fluid mechanics. These are *conservation of mass*, *conservation of momentum*, and *conservation of energy*. In addition, two other postulates, *conservation of moment of momentum* (angular momentum) and the *entropy inequality* (second law of thermodynamics) have occasional use. The conservation principles may be applied either to material systems or to control volumes in space. Most often, control volumes are used. The control volumes may be either of finite or differential size, resulting in either **algebraic** or **differential** conservation equations, respectively. These are often called **macroscopic** and **microscopic** balance equations.

**Macroscopic Equations** An arbitrary control volume of finite size  $V_a$  is bounded by a surface of area  $A_a$  with an outwardly directed unit normal vector  $\mathbf{n}$ . The control volume is not necessarily fixed in space. Its boundary moves with velocity  $\mathbf{w}$ . The fluid velocity is  $\mathbf{v}$ . Figure 6-3 shows the arbitrary control volume.

**Mass Balance** Applied to the control volume, the principle of conservation of mass may be written as (Whitaker, *Introduction to Fluid Mechanics*, Prentice-Hall, Englewood Cliffs, N.J., 1968, Krieger, Huntington, N.Y., 1981)

$$\frac{d}{dt} \int_{V_a} \rho dV + \int_{A_a} \rho(\mathbf{v} - \mathbf{w}) \cdot \mathbf{n} dA = 0 \quad (6-8)$$

This equation is also known as the **continuity** equation.

FIG. 6-3 Arbitrary control volume for application of conservation equations.

FIG. 6-4 Fixed control volume with one inlet and one outlet.

Simplified forms of Eq. (6-8) apply to special cases frequently found in practice. For a control volume fixed in space with one inlet of area  $A_1$  through which an incompressible fluid enters the control volume at an average velocity  $V_1$ , and one outlet of area  $A_2$  through which fluid leaves at an average velocity  $V_2$ , as shown in Fig. 6-4, the continuity equation becomes

$$V_1 A_1 = V_2 A_2 \quad (6-9)$$

The average velocity across a surface is given by

$$V = (1/A) \int_A v dA$$

where  $v$  is the local velocity component perpendicular to the inlet surface. The volumetric flow rate  $Q$  is the product of average velocity and the cross-sectional area,  $Q = VA$ . The average **mass velocity** is  $G = \rho V$ . For steady flows through fixed control volumes with multiple inlets and/or outlets, conservation of mass requires that the sum of inlet mass flow rates equals the sum of outlet mass flow rates. For incompressible flows through fixed control volumes, the sum of inlet flow rates (mass or volumetric) equals the sum of exit flow rates, whether the flow is steady or unsteady.

**Momentum Balance** Since momentum is a vector quantity, the momentum balance is a vector equation. Where gravity is the only body force acting on the fluid, the linear momentum principle, applied to the arbitrary control volume of Fig. 6-3, results in the following expression (Whitaker, *ibid.*).

$$\frac{d}{dt} \int_{V_a} \rho \mathbf{v} dV + \int_{A_a} \rho \mathbf{v}(\mathbf{v} - \mathbf{w}) \cdot \mathbf{n} dA = \int_{V_a} \rho \mathbf{g} dV + \int_{A_a} \mathbf{t}_n dA \quad (6-10)$$

Here  $\mathbf{g}$  is the gravity vector and  $\mathbf{t}_n$  is the force per unit area exerted by the surroundings on the fluid in the control volume. The integrand of the area integral on the left-hand side of Eq. (6-10) is nonzero only on the entrance and exit portions of the control volume boundary. For the special case of steady flow at a mass flow rate  $\dot{m}$  through a control volume fixed in space with one inlet and one outlet (Fig. 6-4), with the inlet and outlet velocity vectors perpendicular to planar inlet and outlet surfaces, giving average velocity vectors  $\mathbf{V}_1$  and  $\mathbf{V}_2$ , the momentum equation becomes

$$\dot{m}(\beta_2 \mathbf{V}_2 - \beta_1 \mathbf{V}_1) = -p_1 \mathbf{A}_1 - p_2 \mathbf{A}_2 + \mathbf{F} + M\mathbf{g} \quad (6-11)$$

where  $M$  is the total mass of fluid in the control volume. The factor  $\beta$  arises from the averaging of the velocity across the area of the inlet or outlet surface. It is the ratio of the area average of the square of velocity magnitude to the square of the area average velocity magnitude. For a uniform velocity,  $\beta = 1$ . For turbulent flow,  $\beta$  is nearly unity, while for laminar pipe flow with a parabolic velocity profile,  $\beta = 4/3$ . The vectors  $\mathbf{A}_1$  and  $\mathbf{A}_2$  have magnitude equal to the areas of the inlet and outlet surfaces, respectively, and are outwardly directed normal to the surfaces. The vector  $\mathbf{F}$  is the force exerted on the fluid by the non-flow boundaries of the control volume. It is also assumed that the stress vector  $\mathbf{t}_n$  is normal to the inlet and outlet surfaces, and that its magnitude may be approximated by the pressure  $p$ . Equation (6-11) may be generalized to multiple inlets and/or outlets. In such cases, the mass flow rates for all the inlets and outlets are not equal. A distinct flow rate  $\dot{m}_i$  applies to each inlet or outlet  $i$ . To generalize the equation,  $-\mathbf{p}\mathbf{A}$  terms for each inlet and outlet,  $-\dot{m}\beta\mathbf{V}$  terms for each inlet, and  $\dot{m}\beta\mathbf{V}$  terms for each outlet are included.

Balance equations for angular momentum, or moment of momentum, may also be written. They are used less frequently than the linear momentum equations. See Whitaker (*Introduction to Fluid Mechanics*, Prentice-Hall, Englewood Cliffs, N.J., 1968, Krieger, Huntington, N.Y., 1981) or Shames (*Mechanics of Fluids*, 3d ed., McGraw-Hill, New York, 1992).

**Total Energy Balance** The total energy balance derives from the first law of thermodynamics. Applied to the arbitrary control volume of Fig. 6-3, it leads to an equation for the rate of change of the sum of internal, kinetic, and gravitational potential energy. In this equation,  $u$  is the internal energy per unit mass,  $v$  is the magnitude of the velocity vector  $\mathbf{v}$ ,  $z$  is elevation,  $g$  is the gravitational acceleration, and  $\mathbf{q}$  is the heat flux vector:

$$\frac{d}{dt} \int_{V_a} \rho \left( u + \frac{v^2}{2} + gz \right) dV + \int_{A_a} \rho \left( u + \frac{v^2}{2} + gz \right) (\mathbf{v} - \mathbf{w}) \cdot \mathbf{n} dA = \int_{A_a} (\mathbf{v} \cdot \mathbf{t}_n) dA - \int_{A_a} (\mathbf{q} \cdot \mathbf{n}) dA \quad (6-12)$$

The first integral on the right-hand side is the rate of work done on the fluid in the control volume by forces at the boundary. It includes both work done by moving solid boundaries and work done at flow entrances and exits. The work done by moving solid boundaries also includes that by such surfaces as pump impellers; this work is called **shaft work**; its rate is  $\dot{W}_s$ .

A useful simplification of the total energy equation applies to a particular set of assumptions. These are a control volume with fixed solid boundaries, except for those producing shaft work, steady state conditions, and mass flow at a rate  $\dot{m}$  through a single planar entrance and a single planar exit (Fig. 6-4), to which the velocity vectors are perpendicular. As with Eq. (6-11), it is assumed that the stress vector  $\mathbf{t}_n$  is normal to the entrance and exit surfaces and may be approximated by the pressure  $p$ . The **equivalent pressure**,  $p + \rho gz$ , is assumed to be uniform across the entrance and exit. The average velocity at the entrance and exit surfaces is denoted by  $V$ . Subscripts 1 and 2 denote the entrance and exit, respectively.

$$h_1 + \alpha_1 \frac{V_1^2}{2} + gz_1 = h_2 + \alpha_2 \frac{V_2^2}{2} + gz_2 - \delta Q - \delta W_s \quad (6-13)$$

Here,  $h$  is the enthalpy per unit mass,  $h = u + p/\rho$ . The shaft work per unit of mass flowing through the control volume is  $\delta W_s = \dot{W}_s/\dot{m}$ . Similarly,  $\delta Q$  is the heat input per unit of mass. The factor  $\alpha$  is the ratio of the cross-sectional area average of the cube of the velocity to the cube of the average velocity. For a uniform velocity profile,  $\alpha = 1$ . In turbulent flow,  $\alpha$  is usually assumed to equal unity; in turbulent pipe flow, it is typically about 1.07. For laminar flow in a circular pipe with a parabolic velocity profile,  $\alpha = 2$ .

**Mechanical Energy Balance, Bernoulli Equation** A balance equation for the sum of kinetic and potential energy may be obtained from the momentum balance by forming the scalar product with the velocity vector. The resulting equation, called the *mechanical energy balance*, contains a term accounting for the dissipation of mechanical energy into thermal energy by viscous forces. The mechanical energy equation is also derivable from the total energy equation in a way that reveals the relationship between the dissipation and entropy generation. The macroscopic mechanical energy balance for the arbitrary control volume of Fig. 6-3 may be written, with  $p =$  thermodynamic pressure, as

$$\frac{d}{dt} \int_{V_a} \rho \left( \frac{v^2}{2} + gz \right) dV + \int_{A_a} \rho \left( \frac{v^2}{2} + gz \right) (\mathbf{v} - \mathbf{w}) \cdot \mathbf{n} dA = \int_{V_a} p \nabla \cdot \mathbf{v} dV + \int_{A_a} (\mathbf{v} \cdot \mathbf{t}_n) dA - \int_{V_a} \Phi dV \quad (6-14)$$

The last term is the rate of viscous energy dissipation to internal energy,  $\dot{E}_v = \int_{V_a} \Phi dV$ , also called the rate of viscous losses. These losses are the origin of frictional pressure drop in fluid flow. Whitaker and Bird, Stewart, and Lightfoot provide expressions for the dissipation function  $\Phi$  for Newtonian fluids in terms of the local velocity gradients. However, when using macroscopic balance equations the local velocity field within the control volume is usually unknown. For such

cases additional information, which may come from empirical correlations, is needed.

For the same special conditions as for Eq. (6-13), the mechanical energy equation is reduced to

$$\alpha_1 \frac{V_1^2}{2} + gz_1 + \delta W_s = \alpha_2 \frac{V_2^2}{2} + gz_2 + \int_{p_1}^{p_2} \frac{dp}{\rho} + l_v \quad (6-15)$$

Here  $l_v = \dot{E}_v/\dot{m}$  is the energy dissipation per unit mass. This equation has been called the **engineering Bernoulli equation**. For an incompressible flow, Eq. (6-15) becomes

$$\frac{p_1}{\rho} + \alpha_1 \frac{V_1^2}{2} + gz_1 + \delta W_s = \frac{p_2}{\rho} + \alpha_2 \frac{V_2^2}{2} + gz_2 + l_v \quad (6-16)$$

The Bernoulli equation can be written for incompressible, inviscid flow along a streamline, where no shaft work is done.

$$\frac{p_1}{\rho} + \frac{V_1^2}{2} + gz_1 = \frac{p_2}{\rho} + \frac{V_2^2}{2} + gz_2 \quad (6-17)$$

Unlike the momentum equation (Eq. [6-11]), the Bernoulli equation is not easily generalized to multiple inlets or outlets.

**Microscopic Balance Equations** Partial differential balance equations express the conservation principles at a point in space. Equations for mass, momentum, total energy, and mechanical energy may be found in Whitaker (ibid.), Bird, Stewart, and Lightfoot (*Transport Phenomena*, Wiley, New York, 1960), and Slattery (*Momentum, Heat and Mass Transfer in Continua*, 2d ed., Krieger, Huntington, N.Y., 1981), for example. These references also present the equations in other useful coordinate systems besides the cartesian system. The coordinate systems are fixed in inertial reference frames. The two most used equations, for mass and momentum, are presented here.

**Mass Balance, Continuity Equation** The continuity equation, expressing conservation of mass, is written in cartesian coordinates as

$$\frac{\partial \rho}{\partial t} + \frac{\partial \rho v_x}{\partial x} + \frac{\partial \rho v_y}{\partial y} + \frac{\partial \rho v_z}{\partial z} = 0 \quad (6-18)$$

In terms of the **substantial derivative**,  $D/Dt$ ,

$$\frac{D\rho}{Dt} \equiv \frac{\partial \rho}{\partial t} + v_x \frac{\partial \rho}{\partial x} + v_y \frac{\partial \rho}{\partial y} + v_z \frac{\partial \rho}{\partial z} = -\rho \left( \frac{\partial v_x}{\partial x} + \frac{\partial v_y}{\partial y} + \frac{\partial v_z}{\partial z} \right) \quad (6-19)$$

The substantial derivative, also called the **material derivative**, is the rate of change in a Lagrangian reference frame, that is, following a material particle. In vector notation the continuity equation may be expressed as

$$\frac{D\rho}{Dt} = -\rho \nabla \cdot \mathbf{v} \quad (6-20)$$

For incompressible flow,

$$\nabla \cdot \mathbf{v} = \frac{\partial v_x}{\partial x} + \frac{\partial v_y}{\partial y} + \frac{\partial v_z}{\partial z} = 0 \quad (6-21)$$

**Stress Tensor** The stress tensor is needed to completely describe the stress state for microscopic momentum balances in multidimensional flows. The components of the stress tensor  $\sigma_{ij}$  give the force in the  $j$  direction on a plane perpendicular to the  $i$  direction, using a sign convention defining a positive stress as one where the fluid with the greater  $i$  coordinate value exerts a force in the positive  $i$  direction on the fluid with the lesser  $i$  coordinate. Several references in fluid mechanics and continuum mechanics provide discussions, to various levels of detail, of stress in a fluid (Denn; Bird, Stewart, and Lightfoot; Schlichting; Fung [*A First Course in Continuum Mechanics*, 2d ed., Prentice-Hall, Englewood Cliffs, N.J., 1977]; Truesdell and Toupin [in Flügge, *Handbuch der Physik*, vol. 3/1, Springer-Verlag, Berlin, 1960]; Slattery [*Momentum, Energy and Mass Transfer in Continua*, 2d ed., Krieger, Huntington, N.Y., 1981]).

The stress has an isotropic contribution due to fluid pressure and dilatation, and a **deviatoric** contribution due to viscous deformation effects. The deviatoric contribution for a Newtonian fluid is the three-dimensional generalization of Eq. (6-2):

$$\tau_{ij} = \mu D_{ij} \quad (6-22)$$

## 6-8 FLUID AND PARTICLE DYNAMICS

The total stress is

$$\sigma_{ij} = (-p + \lambda \nabla \cdot \mathbf{v}) \delta_{ij} + \tau_{ij} \quad (6-23)$$

The identity tensor  $\delta_{ij}$  is zero for  $i \neq j$  and unity for  $i = j$ . The coefficient  $\lambda$  is a material property related to the **bulk viscosity**,  $\kappa = \lambda + 2\mu/3$ . There is considerable uncertainty about the value of  $\kappa$ . Traditionally, Stokes' hypothesis,  $\kappa = 0$ , has been invoked, but the validity of this hypothesis is doubtful (Slattery, *ibid.*). For incompressible flow, the value of bulk viscosity is immaterial as Eq. (6-23) reduces to

$$\sigma_{ij} = -p \delta_{ij} + \tau_{ij} \quad (6-24)$$

Similar generalizations to multidimensional flow are necessary for non-Newtonian constitutive equations.

**Cauchy Momentum and Navier-Stokes Equations** The differential equations for conservation of momentum are called the **Cauchy momentum equations**. These may be found in general form in most fluid mechanics texts (e.g., Slattery [*ibid.*]; Denn; Whitaker; and Schlichting). For the important special case of an incompressible Newtonian fluid with constant viscosity, substitution of Eqs. (6-22) and (6-24) leads to the **Navier-Stokes equations**, whose three Cartesian components are

$$\begin{aligned} \rho \left( \frac{\partial v_x}{\partial t} + v_x \frac{\partial v_x}{\partial x} + v_y \frac{\partial v_x}{\partial y} + v_z \frac{\partial v_x}{\partial z} \right) \\ = - \frac{\partial p}{\partial x} + \mu \left( \frac{\partial^2 v_x}{\partial x^2} + \frac{\partial^2 v_x}{\partial y^2} + \frac{\partial^2 v_x}{\partial z^2} \right) + \rho g_x \end{aligned} \quad (6-25)$$

$$\begin{aligned} \rho \left( \frac{\partial v_y}{\partial t} + v_x \frac{\partial v_y}{\partial x} + v_y \frac{\partial v_y}{\partial y} + v_z \frac{\partial v_y}{\partial z} \right) \\ = - \frac{\partial p}{\partial y} + \mu \left( \frac{\partial^2 v_y}{\partial x^2} + \frac{\partial^2 v_y}{\partial y^2} + \frac{\partial^2 v_y}{\partial z^2} \right) + \rho g_y \end{aligned} \quad (6-26)$$

$$\begin{aligned} \rho \left( \frac{\partial v_z}{\partial t} + v_x \frac{\partial v_z}{\partial x} + v_y \frac{\partial v_z}{\partial y} + v_z \frac{\partial v_z}{\partial z} \right) \\ = - \frac{\partial p}{\partial z} + \mu \left( \frac{\partial^2 v_z}{\partial x^2} + \frac{\partial^2 v_z}{\partial y^2} + \frac{\partial^2 v_z}{\partial z^2} \right) + \rho g_z \end{aligned} \quad (6-27)$$

In vector notation,

$$\rho \frac{D\mathbf{v}}{Dt} = \frac{\partial \mathbf{v}}{\partial t} + (\mathbf{v} \cdot \nabla) \mathbf{v} = -\nabla p + \mu \nabla^2 \mathbf{v} + \rho \mathbf{g} \quad (6-28)$$

The pressure and gravity terms may be combined by replacing the pressure  $p$  by the equivalent pressure  $P = p + \rho g z$ . The left-hand side terms of the Navier-Stokes equations are the **inertial terms**, while the terms including viscosity  $\mu$  are the **viscous terms**. Limiting cases under which the Navier-Stokes equations may be simplified include **creeping flows** in which the inertial terms are neglected, **potential flows** (inviscid or irrotational flows) in which the viscous terms are neglected, and **boundary layer** and **lubrication** flows in which certain terms are neglected based on scaling arguments. Creeping flows are described by Happel and Brenner (*Low Reynolds Number Hydrodynamics*, Prentice-Hall, Englewood Cliffs, N.J., 1965); potential flows by Lamb (*Hydrodynamics*, 6th ed., Dover, New York, 1945) and Milne-Thompson (*Theoretical Hydrodynamics*, 5th ed., Macmillan, New York, 1968); boundary layer theory by Schlichting (*Boundary Layer Theory*, 8th ed., McGraw-Hill, New York, 1987); and lubrication theory by Batchelor (*An Introduction to Fluid Dynamics*, Cambridge University, Cambridge, 1967) and Denn (*Process Fluid Mechanics*, Prentice-Hall, Englewood Cliffs, N.J., 1980).

Because the Navier-Stokes equations are first-order in pressure and second-order in velocity, their solution requires one pressure boundary condition and two velocity boundary conditions (for each velocity component) to completely specify the solution. The **no slip** condition, which requires that the fluid velocity equal the velocity of any bounding solid surface, occurs in most problems. Specification of velocity is a type of boundary condition sometimes called a *Dirichlet condition*. Often boundary conditions involve stresses, and thus velocity gradients, rather

than the velocities themselves. Specification of velocity derivatives is a *Neumann boundary condition*. For example, at the boundary between a viscous liquid and a gas, it is often assumed that the liquid shear stresses are zero. In numerical solution of the Navier-Stokes equations, Dirichlet and Neumann, or **essential** and **natural**, boundary conditions may be satisfied by different means.

**Fluid statics**, discussed in Sec. 10 of the *Handbook* in reference to pressure measurement, is the branch of fluid mechanics in which the fluid velocity is either zero or is uniform and constant relative to an inertial reference frame. With velocity gradients equal to zero, the momentum equation reduces to a simple expression for the pressure field,  $\nabla p = \rho \mathbf{g}$ . Letting  $z$  be directed vertically upward, so that  $g_z = -g$  where  $g$  is the gravitational acceleration (9.806 m/s<sup>2</sup>), the pressure field is given by

$$dp/dz = -\rho g \quad (6-29)$$

This equation applies to any incompressible or compressible static fluid. For an incompressible liquid, pressure varies linearly with depth. For compressible gases,  $p$  is obtained by integration accounting for the variation of  $\rho$  with  $z$ .

The **force exerted on a submerged planar surface** of area  $A$  is given by  $F = p_c A$  where  $p_c$  is the pressure at the geometrical **centroid** of the surface. The **center of pressure**, the point of application of the net force, is always lower than the centroid. For details see, for example, Shames, where may also be found discussion of forces on **curved surfaces**, **buoyancy**, and **stability of floating bodies**.

**Examples** Four examples follow, illustrating the application of the conservation equations to obtain useful information about fluid flows.

**Example 1: Force Exerted on a Reducing Bend** An incompressible fluid flows through a reducing elbow (Fig. 6-5) situated in a horizontal plane. The inlet velocity  $V_1$  is given and the pressures  $p_1$  and  $p_2$  are measured. Selecting the inlet and outlet surfaces 1 and 2 as shown, the continuity equation Eq. (6-9) can be used to find the exit velocity  $V_2 = V_1 A_1 / A_2$ . The mass flow rate is obtained by  $\dot{m} = \rho V_1 A_1$ .

Assume that the velocity profile is nearly uniform so that  $\beta$  is approximately unity. The force exerted on the fluid by the bend has  $x$  and  $y$  components; these can be found from Eq. (6-11). The  $x$  component gives

$$F_x = \dot{m}(V_{2x} - V_{1x}) + p_1 A_{1x} + p_2 A_{2x}$$

while the  $y$  component gives

$$F_y = \dot{m}(V_{2y} - V_{1y}) + p_1 A_{1y} + p_2 A_{2y}$$

The velocity components are  $V_{1x} = V_1$ ,  $V_{1y} = 0$ ,  $V_{2x} = V_2 \cos \theta$ , and  $V_{2y} = V_2 \sin \theta$ . The area vector components are  $A_{1x} = -A_1$ ,  $A_{1y} = 0$ ,  $A_{2x} = A_2 \cos \theta$ , and  $A_{2y} = A_2 \sin \theta$ . Therefore, the force components may be calculated from

$$F_x = \dot{m}(V_2 \cos \theta - V_1) - p_1 A_1 + p_2 A_2 \cos \theta$$

$$F_y = \dot{m} V_2 \sin \theta + p_2 A_2 \sin \theta$$

The force acting on the fluid is  $\mathbf{F}$ ; the equal and opposite force exerted by the fluid on the bend is  $-\mathbf{F}$ .

**FIG. 6-5** Force at a reducing bend.  $\mathbf{F}$  is the force exerted by the bend on the fluid. The force exerted by the fluid on the bend is  $-\mathbf{F}$ .

FIG. 6-6 Draft-tube ejector.

**Example 2: Simplified Ejector** Figure 6-6 shows a very simplified sketch of an ejector, a device that uses a high velocity primary fluid to pump another (secondary) fluid. The continuity and momentum equations may be applied on the control volume with inlet and outlet surfaces 1 and 2 as indicated in the figure. The cross-sectional area is uniform,  $A_1 = A_2 = A$ . Let the mass flow rates and velocities of the primary and secondary fluids be  $\dot{m}_p, \dot{m}_s, V_p$  and  $V_s$ . Assume for simplicity that the density is uniform. Conservation of mass gives  $\dot{m}_2 = \dot{m}_p + \dot{m}_s$ . The exit velocity is  $V_2 = \dot{m}_2/(\rho A)$ . The principle momentum exchange in the ejector occurs between the two fluids. Relative to this exchange, the force exerted by the walls of the device are found to be small. Therefore, the force term  $F$  is neglected from the momentum equation. Written in the flow direction, assuming uniform velocity profiles, and using the extension of Eq. (6-11) for multiple inlets, it gives the pressure rise developed by the device:

$$(p_2 - p_1)A = (\dot{m}_p + \dot{m}_s)V_2 - \dot{m}_p V_p - \dot{m}_s V_s$$

Application of the momentum equation to ejectors of other types is discussed in Lapple (*Fluid and Particle Dynamics*, University of Delaware, Newark, 1951) and in Sec. 10 of the *Handbook*.

**Example 3: Venturi Flowmeter** An incompressible fluid flows through the venturi flowmeter in Fig. 6-7. An equation is needed to relate the flow rate  $Q$  to the pressure drop measured by the manometer. This problem can be solved using the mechanical energy balance. In a well-made venturi, viscous losses are negligible, the pressure drop is entirely the result of acceleration into the throat, and the flow rate predicted neglecting losses is quite accurate. The inlet area is  $A$  and the throat area is  $a$ .

With control surfaces at 1 and 2 as shown in the figure, Eq. (6-17) in the absence of losses and shaft work gives

$$\frac{p_1}{\rho} + \frac{V_1^2}{2} = \frac{p_2}{\rho} + \frac{V_2^2}{2}$$

The continuity equation gives  $V_2 = V_1 A/a$ , and  $V_1 = Q/A$ . The pressure drop measured by the manometer is  $p_1 - p_2 = (\rho_m - \rho)g\Delta z$ . Substituting these relations into the energy balance and rearranging, the desired expression for the flow rate is found.

$$Q = \frac{1}{A} \sqrt{\frac{2(\rho_m - \rho)g\Delta z}{\rho[(A/a)^2 - 1]}}$$

**Example 4: Plane Poiseuille Flow** An incompressible Newtonian fluid flows at a steady rate in the  $x$  direction between two very large flat plates, as shown in Fig. 6-8. The flow is laminar. The velocity profile is to be found. This example is found in most fluid mechanics textbooks; the solution presented here closely follows Denn.

FIG. 6-7 Venturi flowmeter.

FIG. 6-8 Plane Poiseuille flow.

This problem requires use of the microscopic balance equations because the velocity is to be determined as a function of position. The boundary conditions for this flow result from the no-slip condition. All three velocity components must be zero at the plate surfaces,  $y = H/2$  and  $y = -H/2$ .

Assume that the flow is **fully developed**, that is, all velocity derivatives vanish in the  $x$  direction. Since the flow field is infinite in the  $z$  direction, all velocity derivatives should be zero in the  $z$  direction. Therefore, velocity components are a function of  $y$  alone. It is also assumed that there is no flow in the  $z$  direction, so  $v_z = 0$ . The continuity equation Eq. (6-21), with  $v_z = 0$  and  $\partial v_x/\partial x = 0$ , reduces to

$$\frac{dv_y}{dy} = 0$$

Since  $v_y = 0$  at  $y = \pm H/2$ , the continuity equation integrates to  $v_y = 0$ . This is a direct result of the assumption of fully developed flow.

The Navier-Stokes equations are greatly simplified when it is noted that  $v_y = v_z = 0$  and  $\partial v_x/\partial x = \partial v_x/\partial z = \partial v_x/\partial t = 0$ . The three components are written in terms of the equivalent pressure  $P$ :

$$0 = -\frac{\partial P}{\partial x} + \mu \frac{\partial^2 v_x}{\partial y^2}$$

$$0 = -\frac{\partial P}{\partial y}$$

$$0 = -\frac{\partial P}{\partial z}$$

The latter two equations require that  $P$  is a function only of  $x$ , and therefore  $\partial P/\partial x = dP/dx$ . Inspection of the first equation shows one term which is a function only of  $x$  and one which is only a function of  $y$ . This requires that both terms are constant. The pressure gradient  $-dP/dx$  is constant. The  $x$ -component equation becomes

$$\frac{d^2 v_x}{dy^2} = \frac{1}{\mu} \frac{dP}{dx}$$

Two integrations of the  $x$ -component equation give

$$v_x = \frac{1}{2\mu} \frac{dP}{dx} y^2 + C_1 y + C_2$$

where the constants of integration  $C_1$  and  $C_2$  are evaluated from the boundary conditions  $v_x = 0$  at  $y = \pm H/2$ . The result is

$$v_x = \frac{H^2}{8\mu} \left( -\frac{dP}{dx} \right) \left[ 1 - \left( \frac{2y}{H} \right)^2 \right]$$

This is a **parabolic** velocity distribution. The average velocity  $V = (1/H) \int_{-H/2}^{H/2} v_x dy$  is

$$V = \frac{H^2}{12\mu} \left( -\frac{dP}{dx} \right)$$

This flow is one-dimensional, as there is only one nonzero velocity component,  $v_x$ , which, along with the pressure, varies in only one coordinate direction.

**INCOMPRESSIBLE FLOW IN PIPES AND CHANNELS**

**Mechanical Energy Balance** The mechanical energy balance, Eq. (6-16), for **fully developed** incompressible flow in a straight circular pipe of constant diameter  $D$  reduces to

$$\frac{p_1}{\rho} + gz_1 = \frac{p_2}{\rho} + gz_2 + l_v \tag{6-30}$$

In terms of the equivalent pressure,  $P \equiv p + \rho gz$ ,

$$P_1 - P_2 = \rho l_v \tag{6-31}$$

The pressure drop due to frictional losses  $l_v$  is proportional to pipe length  $L$  for fully developed flow and may be denoted as the (positive) quantity  $\Delta P \equiv P_1 - P_2$ .

FIG. 6-9 Fanning Friction Factors. Reynolds number  $Re = DV\rho/\mu$ , where  $D$  = pipe diameter,  $V$  = velocity,  $\rho$  = fluid density, and  $\mu$  = fluid viscosity. (Based on Moody, *Trans. ASME*, **66**, 671 [1944].)

**Friction Factor and Reynolds Number** For a Newtonian fluid in a smooth pipe, dimensional analysis relates the frictional pressure drop per unit length  $\Delta P/L$  to the pipe diameter  $D$ , density  $\rho$ , viscosity  $\mu$ , and average velocity  $V$  through two dimensionless groups, the **Fanning friction factor**  $f$  and the **Reynolds number**  $Re$ .

$$f \equiv \frac{D\Delta P}{2\rho V^2 L} \tag{6-32}$$

$$Re \equiv \frac{DV\rho}{\mu} \tag{6-33}$$

For smooth pipe, the friction factor is a function only of the Reynolds number. In rough pipe, the relative roughness  $\epsilon/D$  also affects the friction factor. Figure 6-9 plots  $f$  as a function of  $Re$  and  $\epsilon/D$ . Values of  $\epsilon$  for various materials are given in Table 6-1. The Fanning friction factor should not be confused with the Darcy friction factor used by Moody (*Trans. ASME*, **66**, 671 [1944]), which is four times greater. Using the momentum equation, the stress at the wall of the pipe may be expressed in terms of the friction factor:

$$\tau_w = f \frac{\rho V^2}{2} \tag{6-34}$$

**Laminar and Turbulent Flow** Below a **critical Reynolds number** of about 2,100, the flow is laminar; over the range  $2,100 < Re < 5,000$  there is a transition to turbulent flow. Reliable correlations for the friction factor in transitional flow are not available. For laminar flow, the Hagen-Poiseuille equation

$$f = \frac{16}{Re} \quad Re \leq 2,100 \tag{6-35}$$

TABLE 6-1 Values of Surface Roughness for Various Materials\*

| Material  | Surface roughness $\epsilon$ , mm |
|---|-----------------------------------|
| Drawn tubing (brass, lead, glass, and the like) | 0.00152                           |
| Commercial steel or wrought iron                | 0.0457                            |
| Asphalted cast iron                             | 0.122                             |
| Galvanized iron                                 | 0.152                             |
| Cast iron                                       | 0.259                             |
| Wood stove                                      | 0.183–0.914                       |
| Concrete  | 0.305–3.05                        |
| Riveted steel                                   | 0.914–9.14                        |

\* From Moody, *Trans. Am. Soc. Mech. Eng.*, **66**, 671–684 (1944); *Mech. Eng.*, **69**, 1005–1006 (1947). Additional values of  $\epsilon$  for various types or conditions of concrete wrought-iron, welded steel, riveted steel, and corrugated-metal pipes are given in Brater and King, *Handbook of Hydraulics*, 6th ed., McGraw-Hill, New York, 1976, pp. 6-12–6-13. To convert millimeters to feet, multiply by  $3.281 \times 10^{-3}$ .

may be derived from the Navier-Stokes equation and is in excellent agreement with experimental data. It may be rewritten in terms of volumetric flow rate,  $Q = V\pi D^2/4$ , as

$$Q = \frac{\pi\Delta P D^4}{128\mu L} \quad Re \leq 2,100 \tag{6-36}$$

For turbulent flow in smooth tubes, the Blasius equation gives the friction factor accurately for a wide range of Reynolds numbers.

$$f = \frac{0.079}{Re^{0.25}} \quad 4,000 < Re < 10^5 \tag{6-37}$$

The Colebrook formula (Colebrook, *J. Inst. Civ. Eng. [London]*, **11**, 133–156 [1938–39]) gives a good approximation for the  $f$ - $Re$ - $(\epsilon/D)$  data for rough pipes over the entire turbulent flow range:

$$\frac{1}{\sqrt{f}} = -4 \log \left[ \frac{\epsilon}{3.7D} + \frac{1.256}{Re\sqrt{f}} \right] \quad Re > 4,000 \quad (6-38)$$

Equation (6-38) was used to construct the curves in the turbulent flow regime in Fig. 6-9.

An equation by Churchill (*Chem. Eng.*, **84**[24], 91–92 [Nov. 7, 1977]) approximating the Colebrook formula offers the advantage of being explicit in  $f$ :

$$\frac{1}{\sqrt{f}} = -4 \log \left[ \frac{0.27\epsilon}{D} + \left( \frac{7}{Re} \right)^{0.9} \right] \quad Re > 4,000 \quad (6-39)$$

Churchill also provided a single equation that may be used for Reynolds numbers in laminar, transitional, and turbulent flow, closely fitting  $f = 16/Re$  in the laminar regime, and the Colebrook formula, Eq. (6-38), in the turbulent regime. It also gives unique, reasonable values in the transition regime, where the friction factor is uncertain.

$$f = 2 \left[ \left( \frac{8}{Re} \right)^{12} + \frac{1}{(A+B)^{32}} \right]^{1/12} \quad (6-40)$$

where

$$A = \left[ 2.457 \ln \frac{1}{(7/Re)^{0.9} + 0.27\epsilon/D} \right]^{16}$$

and

$$B = \left( \frac{37,530}{Re} \right)^{16}$$

In laminar flow,  $f$  is independent of  $\epsilon/D$ . In turbulent flow, the friction factor for rough pipe follows the smooth tube curve for a range of Reynolds numbers (hydraulically smooth flow). For greater Reynolds numbers,  $f$  deviates from the smooth pipe curve, eventually becoming independent of  $Re$ . This region, often called *complete turbulence*, is frequently encountered in commercial pipe flows.

Two common pipe flow problems are calculation of pressure drop given the flow rate (or velocity) and calculation of flow rate (or velocity) given the pressure drop. When flow rate is given, the Reynolds number may be calculated directly to determine the flow regime, so that the appropriate relations between  $f$  and  $Re$  (or pressure drop and flow rate or velocity) can be selected. When flow rate is specified and the flow is turbulent, Eq. (6-39) or (6-40), being explicit in  $f$ , may be preferable to Eq. (6-38), which is implicit in  $f$  and pressure drop.

When the pressure drop is given and the velocity and flow rate are to be determined, the Reynolds number cannot be computed directly, since the velocity is unknown. Instead of guessing and checking the flow regime, it may be useful to observe that the quantity  $Re\sqrt{f} = (D^{3/2}/\mu) \sqrt{\rho \Delta P / (2L)}$ , appearing in the Colebrook equation (6-38), does not include velocity and so can be computed directly. The upper limit  $Re = 2,100$  for laminar flow and use of Eq. (6-35) corresponds to  $Re\sqrt{f} = 183$ . For smooth pipe, the lower limit  $Re = 4,000$  for the Colebrook equation corresponds to  $Re\sqrt{f} = 400$ . Thus, at least for smooth pipes, the flow regime can be determined without trial and error from  $\Delta P/L$ ,  $\mu$ ,  $\rho$ , and  $D$ . When pressure drop is given, Eq. (6-38), being explicit in velocity, is preferable to Eqs. (6-39) and (6-40), which are implicit in velocity.

As Fig. 6-9 suggests, the friction factor is uncertain in the transition range, and a conservative choice should be made for design purposes.

**Velocity Profiles** In laminar flow, the solution of the Navier-Stokes equation, corresponding to the Hagen-Poiseuille equation, gives the velocity  $v$  as a function of radial position  $r$  in a circular pipe of radius  $R$  in terms of the average velocity  $V = Q/A$ . The **parabolic** profile, with centerline velocity twice the average velocity, is shown in Fig. 6-10.

$$v = 2V \left( 1 - \frac{r^2}{R^2} \right) \quad (6-41)$$

In turbulent flow, the velocity profile is much more blunt, with most of the velocity gradient being in a region near the wall, described by a **universal** velocity profile. It is characterized by a **viscous sublayer**, a **turbulent core**, and a **buffer zone** in between.

FIG. 6-10 Parabolic velocity profile for laminar flow in a pipe, with average velocity  $V$ .

Viscous sublayer

$$u_+ = y_+ \quad \text{for} \quad y_+ < 5 \quad (6-42)$$

Buffer zone

$$u_+ = 5.00 \ln y_+ - 3.05 \quad \text{for} \quad 5 < y_+ < 30 \quad (6-43)$$

Turbulent core

$$u_+ = 2.5 \ln y_+ + 5.5 \quad \text{for} \quad y_+ > 30 \quad (6-44)$$

Here,  $u_+ = v/u_*$  is the dimensionless, time-averaged axial velocity,  $u_* = \sqrt{\tau_w/\rho}$  is the **friction velocity** and  $\tau_w = f\rho V^2/2$  is the wall stress. The friction velocity is of the order of the root mean square velocity fluctuation perpendicular to the wall in the turbulent core. The dimensionless distance from the wall is  $y_+ = y u_* \rho / \mu$ . The universal velocity profile is valid in the wall region for any cross-sectional channel shape. For incompressible flow in constant diameter circular pipes,  $\tau_w = D\Delta P/4L$  where  $\Delta P$  is the pressure drop in length  $L$ . In circular pipes, Eq. (6-44) gives a surprisingly good fit to experimental results over the entire cross section of the pipe, even though it is based on assumptions which are valid only near the pipe wall.

For rough pipes, the velocity profile in the turbulent core is given by

$$u_+ = 2.5 \ln y/\epsilon + 8.5 \quad \text{for} \quad y_+ > 30 \quad (6-45)$$

when the dimensionless roughness  $\epsilon_+ = \epsilon u_* \rho / \mu$  is greater than 5 to 10; for smaller  $\epsilon_+$ , the velocity profile in the turbulent core is unaffected by roughness.

For velocity profiles in the transition region, see Patel and Head (*J. Fluid Mech.*, **38**, part 1, 181–201 [1969]) where profiles over the range  $1,500 < Re < 10,000$  are reported.

**Entrance and Exit Effects** In the entrance region of a pipe, some distance is required for the flow to adjust from upstream conditions to the fully developed flow pattern. This distance depends on the Reynolds number and on the flow conditions upstream. For a uniform velocity profile at the pipe entrance, the computed length in laminar flow required for the centerline velocity to reach 99 percent of its fully developed value is (Dombrowski, Fomeny, Ookawara, and Riza, *Can. J. Chem. Engr.*, **71**, 472–476 [1993])

$$L_{\text{ent}}/D = 0.370 \exp(-0.148Re) + 0.0550Re + 0.260 \quad (6-46)$$

In turbulent flow, the entrance length is about

$$L_{\text{ent}}/D = 40 \quad (6-47)$$

The frictional losses in the entrance region are larger than those for the same length of fully developed flow. (See the subsection, “Frictional Losses in Pipeline Elements,” following.) At the pipe exit, the velocity profile also undergoes rearrangement, but the exit length is much shorter than the entrance length. At low  $Re$ , it is about one pipe radius. At  $Re > 100$ , the exit length is essentially 0.

**Residence Time Distribution** For laminar Newtonian pipe flow, the cumulative residence time distribution  $F(\theta)$  is given by

$$F(\theta) = 0 \quad \text{for} \quad \theta < \frac{\theta_{\text{avg}}}{2}$$

$$F(\theta) = 1 - \frac{1}{4} \left( \frac{\theta_{\text{avg}}}{\theta} \right)^2 \quad \text{for} \quad \theta \geq \frac{\theta_{\text{avg}}}{2} \quad (6-48)$$

where  $F(\theta)$  is the fraction of material which resides in the pipe for less than time  $\theta$  and  $\theta_{\text{avg}}$  is the average residence time,  $\theta = V/L$ .

The residence time distribution in long transfer lines may be made narrower (more uniform) with the use of **flow inverters** or **static mixing elements**. These devices exchange fluid between the wall and central regions. Variations on the concept may be used to provide effective mixing of the fluid. See Godfrey ("Static Mixers," in Harnby, Edwards, and Nienow, *Mixing in the Process Industries*, 2d ed., Butterworth Heinemann, Oxford, 1992); Etchells and Meyer ("Mixing in Pipelines," in Paul, Atiemo-Obeng, and Kresta, *Handbook of Industrial Mixing*, Wiley Interscience, Hoboken, N.J., 2004).

A theoretically derived equation for laminar flow in helical pipe coils by Ruthven (*Chem. Eng. Sci.*, **26**, 1113–1121 [1971]; **33**, 628–629 [1978]) is given by

$$F(\theta) = 1 - \left(\frac{1}{4}\right) \left[\frac{\theta_{\text{avg}}}{\theta}\right]^{2.51} \quad \text{for} \quad 0.5 < \frac{\theta_{\text{avg}}}{\theta} < 1.63 \quad (6-49)$$

and was substantially confirmed by Trivedi and Vasudeva (*Chem. Eng. Sci.*, **29**, 2291–2295 [1974]) for  $0.6 < \text{De} < 6$  and  $0.0036 < D/D_c < 0.097$  where  $\text{De} = \text{Re}\sqrt{D/D_c}$  is the Dean number and  $D_c$  is the diameter of curvature of the coil. Measurements by Saxena and Nigam (*Chem. Eng. Sci.*, **34**, 425–426 [1979]) indicate that such a distribution will hold for  $\text{De} > 1$ . The residence time distribution for helical coils is narrower than for straight circular pipes, due to the secondary flow which exchanges fluid between the wall and center regions.

In turbulent flow, axial mixing is usually described in terms of turbulent diffusion or dispersion coefficients, from which cumulative residence time distribution functions can be computed. Davies (*Turbulence Phenomena*, Academic, New York, 1972, p. 93) gives  $D_L = 1.01\text{vRe}^{0.875}$  for the longitudinal dispersion coefficient. Levenspiel (*Chemical Reaction Engineering*, 2d ed., Wiley, New York, 1972, pp. 253–278) discusses the relations among various residence time distribution functions, and the relation between dispersion coefficient and residence time distribution.

**Noncircular Channels** Calculation of frictional pressure drop in noncircular channels depends on whether the flow is laminar or turbulent, and on whether the channel is full or open. For **turbulent flow in ducts running full**, the **hydraulic diameter**  $D_H$  should be substituted for  $D$  in the friction factor and Reynolds number definitions, Eqs. (6-32) and (6-33). The hydraulic diameter is defined as **four times the channel cross-sectional area divided by the wetted perimeter**. For example, the hydraulic diameter for a circular pipe is  $D_H = D$ , for an annulus of inner diameter  $d$  and outer diameter  $D$ ,  $D_H = D - d$ , for a rectangular duct of sides  $a, b$ ,  $D_H = ab/[2(a + b)]$ . The **hydraulic radius**  $R_H$  is defined as **one-fourth** of the hydraulic diameter.

With the hydraulic diameter substituted for  $D$  in  $f$  and  $\text{Re}$ , Eqs. (6-37) through (6-40) are good approximations. Note that  $V$  appearing in  $f$  and  $\text{Re}$  is the actual average velocity  $V = Q/A$ ; for noncircular pipes; it is **not**  $Q/(\pi D_H^2/4)$ . The pressure drop should be calculated from the friction factor for noncircular pipes. Equations relating  $Q$  to  $\Delta P$  and  $D$  for circular pipes **may not be used** for noncircular pipes with  $D$  replaced by  $D_H$  because  $V \neq Q/(\pi D_H^2/4)$ .

Turbulent flow in noncircular channels is generally accompanied by secondary flows perpendicular to the axial flow direction (Schlichting). These flows may cause the pressure drop to be slightly greater than that computed using the hydraulic diameter method. For data on pressure drop in annuli, see Brighton and Jones (*J. Basic Eng.*, **86**, 835–842 [1964]); Okiishi and Serovy (*J. Basic Eng.*, **89**, 823–836 [1967]); and Lawn and Elliot (*J. Mech. Eng. Sci.*, **14**, 195–204 [1972]). For rectangular ducts of large aspect ratio, Dean (*J. Fluids Eng.*, **100**, 215–233 [1978]) found that the numerator of the exponent in the Blasius equation (6-37) should be increased to 0.0868. Jones (*J. Fluids Eng.*, **98**, 173–181 [1976]) presents a method to improve the estimation of friction factors for rectangular ducts using a modification of the hydraulic diameter-based Reynolds number.

The hydraulic diameter method does not work well for **laminar flow** because the shape affects the flow resistance in a way that cannot be expressed as a function only of the ratio of cross-sectional area to wetted perimeter. For some shapes, the Navier-Stokes equations have been integrated to yield relations between flow rate and pressure drop. These relations may be expressed in terms of **equivalent diameters**  $D_E$  defined to make the relations reduce to the second form of the Hagen-Poiseuille equation, Eq. (6-36); that is,  $D_E \equiv$

$(128Q\mu L/\pi\Delta P)^{1/4}$ . **Equivalent diameters are not the same as hydraulic diameters**. Equivalent diameters yield the correct relation between flow rate and pressure drop when substituted into Eq. (6-36), but not Eq. (6-35) because  $V \neq Q/(\pi D_E/4)$ . Equivalent diameter  $D_E$  is not to be used in the friction factor and Reynolds number;  $f \neq 16/\text{Re}$  using the equivalent diameters defined in the following. This situation is, by arbitrary definition, opposite to that for the hydraulic diameter  $D_H$  used for turbulent flow.

**Ellipse**, semiaxes  $a$  and  $b$  (Lamb, *Hydrodynamics*, 6th ed., Dover, New York, 1945, p. 587):

$$D_E = \left(\frac{32a^3b^3}{a^2 + b^2}\right)^{1/4} \quad (6-50)$$

**Rectangle**, width  $a$ , height  $b$  (Owen, *Trans. Am. Soc. Civ. Eng.*, **119**, 1157–1175 [1954]):

$$D_E = \left(\frac{128ab^3}{\pi K}\right)^{1/4} \quad (6-51)$$

|         |       |       |       |       |       |       |       |          |
|---------|-------|-------|-------|-------|-------|-------|-------|----------|
| $a/b =$ | 1     | 1.5   | 2     | 3     | 4     | 5     | 10    | $\infty$ |
| $K =$   | 28.45 | 20.43 | 17.49 | 15.19 | 14.24 | 13.73 | 12.81 | 12       |

**Annulus**, inner diameter  $D_1$ , outer diameter  $D_2$  (Lamb, op. cit., p. 587):

$$D_E = \left\{ (D_2^2 - D_1^2) \left[ D_2^2 + D_1^2 - \frac{D_2^2 - D_1^2}{\ln(D_2/D_1)} \right] \right\}^{1/4} \quad (6-52)$$

For isosceles triangles and regular polygons, see Sparrow (*AIChE J.*, **8**, 599–605 [1962]), Carlson and Irvine (*J. Heat Transfer*, **83**, 441–444 [1961]), Cheng (*Proc. Third Int. Heat Transfer Conf.*, New York, **1**, 64–76 [1966]), and Shih (*Can. J. Chem. Eng.*, **45**, 285–294 [1967]).

The critical Reynolds number for **transition from laminar to turbulent flow** in noncircular channels varies with channel shape. In rectangular ducts,  $1,900 < \text{Re}_c < 2,800$  (Hanks and Ruo, *Ind. Eng. Chem. Fundam.*, **5**, 558–561 [1966]). In triangular ducts,  $1,600 < \text{Re}_c < 1,800$  (Cope and Hanks, *Ind. Eng. Chem. Fundam.*, **11**, 106–117 [1972]; Bandopadhyay and Hinwood, *J. Fluid Mech.*, **59**, 775–783 [1973]).

**Nonisothermal Flow** For nonisothermal flow of **liquids**, the friction factor may be increased if the liquid is being cooled or decreased if the liquid is being heated, because of the effect of temperature on viscosity near the wall. In shell and tube heat-exchanger design, the recommended practice is to first estimate  $f$  using the bulk mean liquid temperature over the tube length. Then, in laminar flow, the result is divided by  $(\mu_w/\mu_e)^{0.23}$  in the case of cooling or  $(\mu_w/\mu_e)^{0.38}$  in the case of heating. For turbulent flow,  $f$  is divided by  $(\mu_w/\mu_e)^{0.11}$  in the case of cooling or  $(\mu_w/\mu_e)^{0.17}$  in case of heating. Here,  $\mu_w$  is the viscosity at the average bulk temperature and  $\mu_e$  is the viscosity at the average wall temperature (Seider and Tate, *Ind. Eng. Chem.*, **28**, 1429–1435 [1936]). In the case of rough commercial pipes, rather than heat-exchanger tubing, it is common for flow to be in the "complete" turbulence regime where  $f$  is independent of  $\text{Re}$ . In such cases, the friction factor should not be corrected for wall temperature. If the liquid density varies with temperature, the average bulk density should be used to calculate the pressure drop from the friction factor. In addition, a (usually small) correction may be applied for acceleration effects by adding the term  $G^2[(1/\rho_2) - (1/\rho_1)]$  from the mechanical energy balance to the pressure drop  $\Delta P = P_1 - P_2$ , where  $G$  is the mass velocity. This acceleration results from small compressibility effects associated with temperature-dependent density. Christiansen and Gordon (*AIChE J.*, **15**, 504–507 [1969]) present equations and charts for frictional loss in laminar nonisothermal flow of Newtonian and non-Newtonian liquids heated or cooled with constant wall temperature.

Frictional dissipation of mechanical energy can result in significant heating of fluids, particularly for very viscous liquids in small channels. Under adiabatic conditions, the bulk liquid temperature rise is given by  $\Delta T = \Delta P/C_p \rho$  for incompressible flow through a channel of constant cross-sectional area. For flow of polymers, this amounts to about 4°C per 10 MPa pressure drop, while for hydrocarbon liquids it is about

6°C per 10 MPa. The temperature rise in laminar flow is highly nonuniform, being concentrated near the pipe wall where most of the dissipation occurs. This may result in significant viscosity reduction near the wall, and greatly increased flow or reduced pressure drop, and a flattened velocity profile. Compensation should generally be made for the heat effect when  $\Delta P$  exceeds 1.4 MPa (203 psi) for adiabatic walls or 3.5 MPa (508 psi) for isothermal walls (Gerard, Steidler, and Appeldoorn, *Ind. Eng. Chem. Fundam.*, **4**, 332–339 [1969]).

**Open Channel Flow** For flow in **open channels**, the data are largely based on experiments with water in turbulent flow, in channels of sufficient roughness that there is no Reynolds number effect. The hydraulic radius approach may be used to estimate a friction factor with which to compute friction losses. Under conditions of **uniform flow** where liquid depth and cross-sectional area do not vary significantly with position in the flow direction, there is a balance between gravitational forces and wall stress, or equivalently between frictional losses and potential energy change. The mechanical energy balance reduces to  $l_v = g(z_1 - z_2)$ . In terms of the friction factor and hydraulic diameter or hydraulic radius,

$$l_v = \frac{2fV^2L}{D_H} = \frac{fV^2L}{2R_H} = g(z_1 - z_2) \quad (6-53)$$

The hydraulic radius is the cross-sectional area divided by the wetted perimeter, where the wetted perimeter *does not include the free surface*. Letting  $S = \sin \theta =$  channel slope (elevation loss per unit length of channel,  $\theta =$  angle between channel and horizontal), Eq. (6-53) reduces to

$$V = \sqrt{\frac{2gSR_H}{f}} \quad (6-54)$$

The most often used friction correlation for open channel flows is due to Manning (*Trans. Inst. Civ. Engrs. Ireland*, **20**, 161 [1891]) and is equivalent to

$$f = \frac{29n^2}{R_H^{1/3}} \quad (6-55)$$

where  $n$  is the channel roughness, with dimensions of (length)<sup>1/6</sup>. Table 6-2 gives roughness values for several channel types.

For gradual changes in channel cross section and liquid depth, and for slopes less than 10°, the momentum equation for a rectangular channel of width  $b$  and liquid depth  $h$  may be written as a differential equation in the flow direction  $x$ .

$$\frac{dh}{dx} (1 - Fr) - Fr \left( \frac{h}{b} \right) \frac{db}{dx} = S - \frac{fV^2(b + 2h)}{2gbh} \quad (6-56)$$

For a given fixed flow rate  $Q = Vbh$ , and channel width profile  $b(x)$ , Eq. (6-56) may be integrated to determine the liquid depth profile

**TABLE 6-2 Average Values of  $n$  for Manning Formula, Eq. (6-55)**

| Surface   | $n$ , m <sup>1/6</sup> | $n$ , ft <sup>1/6</sup> |

SOURCE: Brater and King, *Handbook of Hydraulics*, 6th ed., McGraw-Hill, New York, 1976, p. 7-22. For detailed information, see Chow, *Open-Channel Hydraulics*, McGraw-Hill, New York, 1959, pp. 110–123.

$h(x)$ . The dimensionless Froude number is  $Fr = V^2/gh$ . When  $Fr = 1$ , the flow is **critical**, when  $Fr < 1$ , the flow is **subcritical**, and when  $Fr > 1$ , the flow is **supercritical**. Surface disturbances move at a wave velocity  $c = \sqrt{gh}$ ; they cannot propagate upstream in supercritical flows. The **specific energy**  $E_{sp}$  is nearly constant.

$$E_{sp} = h + \frac{V^2}{2g} \quad (6-57)$$

This equation is cubic in liquid depth. Below a minimum value of  $E_{sp}$  there are no real positive roots; above the minimum value there are two positive real roots. At this minimum value of  $E_{sp}$  the flow is critical; that is,  $Fr = 1$ ,  $V = \sqrt{gh}$ , and  $E_{sp} = (3/2)h$ . Near critical flow conditions, wave motion and sudden depth changes called **hydraulic jumps** are likely. Chow (*Open Channel Hydraulics*, McGraw-Hill, New York, 1959) discusses the numerous surface profile shapes which may exist in nonuniform open channel flows.

For flow over a sharp-crested weir of width  $b$  and height  $L$ , from a liquid depth  $H$ , the flow rate is given approximately by

$$Q = \frac{2}{3} C_d b \sqrt{2g} (H - L)^{3/2} \quad (6-58)$$

where  $C_d \approx 0.6$  is a discharge coefficient. Flow through notched weirs is described under flow meters in Sec. 10 of the *Handbook*.

**Non-Newtonian Flow** For **isothermal laminar flow** of time-independent non-Newtonian liquids, integration of the Cauchy momentum equations yields the fully developed velocity profile and flow rate–pressure drop relations. For the **Bingham plastic** fluid described by Eq. (6-3), in a pipe of diameter  $D$  and a pressure drop per unit length  $\Delta P/L$ , the flow rate is given by

$$Q = \frac{\pi D^3 \tau_w}{32\mu_\infty} \left[ 1 - \frac{4\tau_y}{3\tau_w} + \frac{\tau_y^4}{3\tau_w^4} \right] \quad (6-59)$$

where the wall stress is  $\tau_w = D\Delta P/(4L)$ . The velocity profile consists of a central nondeforming plug of radius  $r_p = 2\tau_y/(\Delta P/L)$  and an annular deforming region. The velocity profile in the annular region is given by

$$v_z = \frac{1}{\mu_\infty} \left[ \frac{\Delta P}{4L} (R^2 - r^2) - \tau_y (R - r) \right] \quad r_p \leq r \leq R \quad (6-60)$$

where  $r$  is the radial coordinate and  $R$  is the pipe radius. The velocity of the central, nondeforming plug is obtained by setting  $r = r_p$  in Eq. (6-60). When  $Q$  is given and Eq. (6-59) is to be solved for  $\tau_w$  and the pressure drop, multiple positive roots for the pressure drop may be found. The root corresponding to  $\tau_w < \tau_y$  is physically unrealizable, as it corresponds to  $r_p > R$  and the pressure drop is insufficient to overcome the yield stress.

For a **power law fluid**, Eq. (6-4), with constant properties  $K$  and  $n$ , the flow rate is given by

$$Q = \pi \left( \frac{\Delta P}{2KL} \right)^{1/n} \left( \frac{n}{1 + 3n} \right) R^{(1 + 3n)/n} \quad (6-61)$$

and the velocity profile by

$$v_z = \left( \frac{\Delta P}{2KL} \right)^{1/n} \left( \frac{n}{1 + n} \right) [R^{(1 + n)/n} - r^{(1 + n)/n}] \quad (6-62)$$

Similar relations for other non-Newtonian fluids may be found in Govier and Aziz and in Bird, Armstrong, and Hassager (*Dynamics of Polymeric Liquids*, vol. 1: *Fluid Mechanics*, Wiley, New York, 1977).

For steady-state laminar flow of any time-independent viscous fluid, at average velocity  $V$  in a pipe of diameter  $D$ , the Rabinowitsch-Mooney relations give a general relationship for the shear rate at the pipe wall.

$$\dot{\gamma}_w = \frac{8V}{D} \left( \frac{1 + 3n'}{4n'} \right) \quad (6-63)$$

where  $n'$  is the slope of a plot of  $D\Delta P/(4L)$  versus  $8V/D$  on logarithmic coordinates,

$$n' = \frac{d \ln [D\Delta P/(4L)]}{d \ln (8V/D)} \quad (6-64)$$

By plotting capillary viscometry data this way, they can be used directly for pressure drop design calculations, or to construct the rheogram for the fluid. For pressure drop calculation, the flow rate and diameter determine the velocity, from which  $SV/D$  is calculated and  $D\Delta P/(4L)$  read from the plot. For a Newtonian fluid,  $n' = 1$  and the shear rate at the wall is  $\dot{\gamma} = SV/D$ . For a power law fluid,  $n' = n$ . To construct a rheogram,  $n'$  is obtained from the slope of the experimental plot at a given value of  $SV/D$ . The shear rate at the wall is given by Eq. (6-63) and the corresponding shear stress at the wall is  $\tau_w = D\Delta P/(4L)$  read from the plot. By varying the value of  $SV/D$ , the shear rate versus shear stress plot can be constructed.

The generalized approach of Metzner and Reed (*AIChE J.*, **1**, 434 [1955]) for time-independent non-Newtonian fluids defines a modified Reynolds number as

$$\text{Re}_{\text{MR}} \equiv \frac{D^n V^{2-n} \rho}{K' 8^{n'-1}} \quad (6-65)$$

where  $K'$  satisfies

$$\frac{D\Delta P}{4L} = K' \left( \frac{SV}{D} \right)^{n'} \quad (6-66)$$

With this definition,  $f = 16/\text{Re}_{\text{MR}}$  is automatically satisfied at the value of  $SV/D$  where  $K'$  and  $n'$  are evaluated. Equation (6-66) may be obtained by integration of Eq. (6-64) only when  $n'$  is a constant, as, for example, the cases of Newtonian and power law fluids. For Newtonian fluids,  $K' = \mu$  and  $n' = 1$ ; for power law fluids,  $K' = K[(1 + 3n)/(4n)]^n$  and  $n' = n$ . For Bingham plastics,  $K'$  and  $n'$  are variable, given as a function of  $\tau_w$  (Metzner, *Ind. Eng. Chem.*, **49**, 1429–1432 [1957]).

$$K = \tau_w^{1-n'} \left[ \frac{\mu_\infty}{1 - 4\tau_y/3\tau_w + (\tau_y/\tau_w)^{4/3}} \right]^{n'} \quad (6-67)$$

$$n' = \frac{1 - 4\tau_y/(3\tau_w) + (\tau_y/\tau_w)^{4/3}}{1 - (\tau_y/\tau_w)^4} \quad (6-68)$$

For laminar flow of power law fluids in channels of noncircular cross section, see Schechter (*AIChE J.*, **7**, 445–448 [1961]), Wheeler and Wissler (*AIChE J.*, **11**, 207–212 [1965]), Bird, Armstrong, and Hassager (*Dynamics of Polymeric Liquids*, vol. 1: *Fluid Mechanics*, Wiley, New York, 1977), and Skelland (*Non-Newtonian Flow and Heat Transfer*, Wiley, New York, 1967).

Steady-state, fully developed laminar flows of viscoelastic fluids in straight, constant-diameter pipes show no effects of viscoelasticity. The viscous component of the constitutive equation may be used to develop the flow rate–pressure drop relations, which apply downstream of the entrance region after viscoelastic effects have disappeared. A similar situation exists for time-dependent fluids.

The **transition to turbulent flow** begins at  $\text{Re}_{\text{MR}}$  in the range of 2,000 to 2,500 (Metzner and Reed, *AIChE J.*, **1**, 434 [1955]). For Bingham plastic materials,  $K'$  and  $n'$  must be evaluated for the  $\tau_w$  condition in question in order to determine  $\text{Re}_{\text{MR}}$  and establish whether the flow is laminar. An alternative method for Bingham plastics is by Hanks (Hanks, *AIChE J.*, **9**, 306 [1963]; **14**, 691 [1968]; Hanks and Pratt, *Soc. Petrol. Engrs. J.*, **7**, 342 [1967]; and Govier and Aziz, pp. 213–215). The transition from laminar to turbulent flow is influenced by **viscoelastic** properties (Metzner and Park, *J. Fluid Mech.*, **20**, 291 [1964]) with the critical value of  $\text{Re}_{\text{MR}}$  increased to beyond 10,000 for some materials.

For **turbulent flow of non-Newtonian fluids**, the design chart of Dodge and Metzner (*AIChE J.*, **5**, 189 [1959]), Fig. 6-11, is most widely used. For Bingham plastic materials in turbulent flow, it is generally assumed that stresses greatly exceed the yield stress, so that the friction factor–Reynolds number relationship for Newtonian fluids applies, with  $\mu_\infty$  substituted for  $\mu$ . This is equivalent to setting  $n' = 1$  and  $\tau_y/\tau_w = 0$  in the Dodge-Metzner method, so that  $\text{Re}_{\text{MR}} = DV\rho/\mu_\infty$ . Wilson and Thomas (*Can. J. Chem. Eng.*, **63**, 539–546 [1985]) give friction factor equations for turbulent flow of power law fluids and Bingham plastic fluids.

Power law fluids:

$$\frac{1}{\sqrt{f}} = \frac{1}{\sqrt{f_N}} + 8.2 \frac{1-n}{1+n} + 1.77 \ln \left( \frac{1+n}{2} \right) \quad (6-69)$$

FIG. 6-11 Fanning friction factor for non-Newtonian flow. The abscissa is defined in Eq. (6-65). (From Dodge and Metzner, *Am. Inst. Chem. Eng. J.*, **5**, 189 [1959].)

where  $f_N$  is the friction factor for Newtonian fluid evaluated at  $\text{Re} = DV\rho/\mu_{\text{eff}}$  where the effective viscosity is

$$\mu_{\text{eff}} = K \left( \frac{3n+1}{4n} \right)^{n-1} \left( \frac{SV}{D} \right)^{n-1} \quad (6-70)$$

Bingham fluids:

$$\frac{1}{\sqrt{f}} = \frac{1}{\sqrt{f_N}} + 1.77 \ln \left( \frac{(1-\xi)^2}{1+\xi} \right) + \xi(10 + 0.884\xi) \quad (6-71)$$

where  $f_N$  is evaluated at  $\text{Re} = DV\rho/\mu_\infty$  and  $\xi = \tau_y/\tau_w$ . Iteration is required to use this equation since  $\tau_w = f\rho V^2/2$ .

**Drag reduction** in turbulent flow can be achieved by adding soluble high molecular weight polymers in extremely low concentration to Newtonian liquids. The reduction in friction is generally believed to be associated with the viscoelastic nature of the solutions effective in the wall region. For a given polymer, there is a minimum molecular weight necessary to initiate drag reduction at a given flow rate, and a critical concentration above which drag reduction will not occur (Kim, Little, and Ting, *J. Colloid Interface Sci.*, **47**, 530–535 [1974]). Drag reduction is reviewed by Hoyt (*J. Basic Eng.*, **94**, 258–285 [1972]); Little, et al. (*Ind. Eng. Chem. Fundam.*, **14**, 283–296 [1975]) and Virk (*AIChE J.*, **21**, 625–656 [1975]). At maximum possible drag reduction in smooth pipes,

$$\frac{1}{\sqrt{f}} = -19 \log \left( \frac{50.73}{\text{Re}\sqrt{f}} \right) \quad (6-72)$$

or, approximately,  $f = \frac{0.58}{\text{Re}^{0.58}}$  (6-73)

for 4,000 <  $\text{Re}$  < 40,000. The actual drag reduction depends on the polymer system. For further details, see Virk (*ibid.*).

**Economic Pipe Diameter, Turbulent Flow** The economic optimum pipe diameter may be computed so that the last increment of investment reduces the operating cost enough to produce the required minimum return on investment. For long cross-country pipelines, alloy pipes of appreciable length and complexity, or pipelines with control valves, detailed analyses of investment and operating costs should be made. Peters and Timmerhaus (*Plant Design and Economics for Chemical Engineers*, 4th ed., McGraw-Hill, New York, 1991) provide a detailed method for determining the economic optimum size. For pipelines of the lengths usually encountered in chemical plants and petroleum refineries, simplified selection charts are often adequate. In many cases there is an economic optimum velocity that is nearly independent of diameter, which may be used to estimate the economic diameter from the flow rate. For low-viscosity liquids in schedule 40 steel pipe, economic optimum velocity is typically in the range of 1.8 to 2.4 m/s (5.9 to 7.9 ft/s). For gases with density ranging

from 0.2 to 20 kg/m<sup>3</sup> (0.013 to 1.25 lbm/ft<sup>3</sup>), the economic optimum velocity is about 40 m/s to 9 m/s (131 to 30 ft/s). Charts and rough guidelines for economic optimum size do not apply to multiphase flows.

**Economic Pipe Diameter, Laminar Flow** Pipelines for the transport of high-viscosity liquids are seldom designed purely on the basis of economics. More often, the size is dictated by operability considerations such as available pressure drop, shear rate, or residence time distribution. Peters and Timmerhaus (ibid., Chap. 10) provide an economic pipe diameter chart for laminar flow. For non-Newtonian fluids, see Skelland (*Non-Newtonian Flow and Heat Transfer*, Chap. 7, Wiley, New York, 1967).

**Vacuum Flow** When gas flows under high vacuum conditions or through very small openings, the continuum hypothesis is no longer appropriate if the channel dimension is not very large compared to the mean free path of the gas. When the mean free path is comparable to the channel dimension, flow is dominated by collisions of molecules with the wall, rather than by collisions between molecules. An approximate expression based on Brown, et al. (*J. Appl. Phys.*, **17**, 802–813 [1946]) for the mean free path is

$$\lambda = \left(\frac{2\mu}{p}\right) \sqrt{\frac{8RT}{\pi M_w}} \quad (6-74)$$

The Knudsen number Kn is the ratio of the mean free path to the channel dimension. For pipe flow, Kn = λ/D. **Molecular flow** is characterized by Kn > 1.0; continuum viscous (laminar or turbulent) flow is characterized by Kn < 0.01. **Transition** or **slip** flow applies over the range 0.01 < Kn < 1.0.

Vacuum flow is usually described with flow variables different from those used for normal pressures, which often leads to confusion. **Pumping speed** S is the actual volumetric flow rate of gas through a flow cross section. **Throughput** Q is the product of pumping speed and absolute pressure. In the SI system, Q has units of Pa·m<sup>3</sup>/s.

$$Q = Sp \quad (6-75)$$

The mass flow rate w is related to the throughput using the ideal gas law.

$$w = \frac{M_w}{RT} Q \quad (6-76)$$

Throughput is therefore proportional to mass flow rate. For a given mass flow rate, throughput is independent of pressure. The relation between throughput and pressure drop Δp = p<sub>1</sub> - p<sub>2</sub> across a flow element is written in terms of the **conductance** C. **Resistance** is the reciprocal of conductance. Conductance has dimensions of volume per time.

$$Q = C\Delta p \quad (6-77)$$

The conductance of a series of flow elements is given by

$$\frac{1}{C} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3} + \dots \quad (6-78)$$

while for elements in parallel,

$$C = C_1 + C_2 + C_3 + \dots \quad (6-79)$$

For a vacuum pump of speed S<sub>p</sub> withdrawing from a vacuum vessel through a connecting line of conductance C, the pumping speed at the vessel is

$$S = \frac{S_p C}{S_p + C} \quad (6-80)$$

**Molecular Flow** Under molecular flow conditions, conductance is independent of pressure. It is proportional to √T/M<sub>w</sub>, with the proportionality constant a function of geometry. For fully developed pipe flow,

$$C = \frac{\pi D^3}{8L} \sqrt{\frac{RT}{M_w}} \quad (6-81)$$

For an orifice of area A,

$$C = 0.40A \sqrt{\frac{RT}{M_w}} \quad (6-82)$$

Conductance equations for several other geometries are given by Ryans and Roper (*Process Vacuum System Design and Operation*, Chap. 2, McGraw-Hill, New York, 1986). For a circular annulus of outer and inner diameters D<sub>1</sub> and D<sub>2</sub> and length L, the method of Guthrie and Wakerling (*Vacuum Equipment and Techniques*, McGraw-Hill, New York, 1949) may be written

$$C = 0.42K \frac{(D_1 - D_2)^2(D_1 + D_2)}{L} \sqrt{\frac{RT}{M_w}} \quad (6-83)$$

where K is a dimensionless constant with values given in Table 6-3.

For a short pipe of circular cross section, the conductance as calculated for an orifice from Eq. (6-82) is multiplied by a correction factor K which may be approximated as (Kennard, *Kinetic Theory of Gases*, McGraw-Hill, New York, 1938, pp. 306–308)

$$K = \frac{1}{1 + (L/D)} \quad \text{for } 0 \leq L/D \leq 0.75 \quad (6-84)$$

$$K = \frac{1 + 0.8(L/D)}{1 + 1.90(L/D) + 0.6(L/D)^2} \quad \text{for } L/D > 0.75 \quad (6-85)$$

For L/D > 100, the error in neglecting the end correction by using the fully developed pipe flow equation (6-81) is less than 2 percent. For rectangular channels, see Normand (*Ind. Eng. Chem.*, **40**, 783–787 [1948]).

Yu and Sparrow (*J. Basic Eng.*, **70**, 405–410 [1970]) give a theoretically derived chart for slot seals with or without a sheet located in or passing through the seal, giving mass flow rate as a function of the ratio of seal plate thickness to gap opening.

**Slip Flow** In the transition region between molecular flow and continuum viscous flow, the conductance for fully developed pipe flow is most easily obtained by the method of Brown, et al. (*J. Appl. Phys.*, **17**, 802–813 [1946]), which uses the parameter

$$X = \sqrt{\frac{8}{\pi}} \left(\frac{\lambda}{D}\right) = \left(\frac{2\mu}{p_m D}\right) \sqrt{\frac{RT}{M}} \quad (6-86)$$

where p<sub>m</sub> is the arithmetic mean absolute pressure. A correction factor F, read from Fig. 6-12 as a function of X, is applied to the conductance

FIG. 6-12 Correction factor for Poiseuille's equation at low pressures. Curve A: experimental curve for glass capillaries and smooth metal tubes. (From Brown, et al., *J. Appl. Phys.*, **17**, 802 [1946].) Curve B: experimental curve for iron pipe (From Riggle, courtesy of E. I. du Pont de Nemours & Co.)

for viscous flow.

$$C = F \frac{\pi D^4 p_m}{128 \mu L} \tag{6-87}$$

For slip flow through **square channels**, see Milligan and Wilkerson (*J. Eng. Ind.*, **95**, 370–372 [1973]). For slip flow through **annuli**, see Maegley and Berman (*Phys. Fluids*, **15**, 780–785 [1972]).

The **pump-down time**  $\theta$  for evacuating a vessel in the absence of air in-leakage is given approximately by

$$\theta = \left( \frac{V_i}{S_0} \right) \ln \left( \frac{p_1 - p_0}{p_2 - p_0} \right) \tag{6-88}$$

where  $V_i$  = volume of vessel plus volume of piping between vessel and pump;  $S_0$  = system speed as given by Eq. (6-80), assumed independent of pressure;  $p_1$  = initial vessel pressure;  $p_2$  = final vessel pressure; and  $p_0$  = lowest pump intake pressure attainable with the pump in question. See Dushman and Lafferty (*Scientific Foundations of Vacuum Technique*, 2d ed., Wiley, New York, 1962).

The amount of inerts which has to be removed by a pumping system after the pump-down stage depends on the in-leakage of air at the various fittings, connections, and so on. Air leakage is often correlated with system volume and pressure, but this approach introduces uncertainty because the number and size of leaks does not necessarily correlate with system volume, and leakage is sensitive to maintenance quality. Ryans and Roper (*Process Vacuum System Design and Operation*, McGraw-Hill, New York, 1986) present a thorough discussion of air leakage.

**FRICIONAL LOSSES IN PIPELINE ELEMENTS**

The viscous or frictional loss term in the mechanical energy balance for most cases is obtained experimentally. For many common fittings found in piping systems, such as expansions, contractions, elbows, and valves, data are available to estimate the losses. Substitution into the energy balance then allows calculation of pressure drop. A common error is to assume that pressure drop and frictional losses are equivalent. Equation (6-16) shows that in addition to frictional losses, other factors such as shaft work and velocity or elevation change influence pressure drop.

Losses  $l_v$  for incompressible flow in sections of straight pipe of constant diameter may be calculated as previously described using the Fanning friction factor:

$$l_v = \frac{\Delta P}{\rho} = \frac{2fV^2L}{D} \tag{6-89}$$

where  $\Delta P$  = drop in equivalent pressure,  $P = p + \rho gz$ , with  $p$  = pressure,  $\rho$  = fluid density,  $g$  = acceleration of gravity, and  $z$  = elevation. Losses in the fittings of a piping network are frequently termed *minor losses* or *miscellaneous losses*. These descriptions are misleading because in process piping fitting losses are often much greater than the losses in straight piping sections.

**Equivalent Length and Velocity Head Methods** Two methods are in common use for estimating fitting loss. One, the **equivalent length** method, reports the losses in a piping element as the length of straight pipe which would have the same loss. For turbulent flows, the equivalent length is usually reported as a number of diameters of pipe of the same size as the fitting connection;  $L_e/D$  is given as

a fixed quantity, independent of  $D$ . This approach tends to be most accurate for a single fitting size and loses accuracy with deviation from this size. For laminar flows,  $L_e/D$  correlations normally have a size dependence through a Reynolds number term.

The other method is the **velocity head** method. The term  $V^2/2g$  has dimensions of length and is commonly called a *velocity head*. Application of the Bernoulli equation to the problem of frictionless discharge at velocity  $V$  through a nozzle at the bottom of a column of liquid of height  $H$  shows that  $H = V^2/2g$ . Thus  $H$  is the liquid head corresponding to the velocity  $V$ . Use of the velocity head to scale pressure drops has wide application in fluid mechanics. Examination of the Navier-Stokes equations suggests that when the inertial terms dominate the viscous terms, pressure gradients are expected to be proportional to  $\rho V^2$  where  $V$  is a characteristic velocity of the flow.

In the velocity head method, the losses are reported as a number of velocity heads  $K$ . Then, the engineering Bernoulli equation for an incompressible fluid can be written

$$p_1 - p_2 = \alpha_2 \frac{\rho V_2^2}{2} - \alpha_1 \frac{\rho V_1^2}{2} + \rho g(z_2 - z_1) + K \frac{\rho V^2}{2} \tag{6-90}$$

where  $V$  is the reference velocity upon which the velocity head loss coefficient  $K$  is based. For a section of straight pipe,  $K = 4fL/D$ .

**Contraction and Entrance Losses** For a **sudden contraction** at a sharp-edged entrance to a pipe or sudden reduction in cross-sectional area of a channel, as shown in Fig. 6-13a, the loss coefficient based on the downstream velocity  $V_2$  is given for **turbulent flow** in Crane Co. Tech Paper 410 (1980) approximately by

$$K = 0.5 \left( 1 - \frac{A_2}{A_1} \right) \tag{6-91}$$

**Example 5: Entrance Loss** Water,  $\rho = 1,000 \text{ kg/m}^3$ , flows from a large vessel through a sharp-edged entrance into a pipe at a velocity in the pipe of 2 m/s. The flow is turbulent. Estimate the pressure drop from the vessel into the pipe.

With  $A_2/A_1 \rightarrow 0$ , the viscous loss coefficient is  $K = 0.5$  from Eq. (6-91). The mechanical energy balance, Eq. (6-16) with  $V_1 = 0$  and  $z_2 - z_1 = 0$  and assuming uniform flow ( $\alpha_2 = 1$ ) becomes

$$p_1 - p_2 = \frac{\rho V_2^2}{2} + 0.5 \frac{\rho V_2^2}{2} = 4,000 + 2,000 = 6,000 \text{ Pa}$$

Note that the total pressure drop consists of 0.5 velocity heads of frictional loss contribution, and 1 velocity head of velocity change contribution. The frictional contribution is a permanent loss of mechanical energy by viscous dissipation. The acceleration contribution is reversible; if the fluid were subsequently decelerated in a frictionless diffuser, a 4,000 Pa pressure rise would occur.

For a **trumpet-shaped** rounded entrance, with a radius of rounding greater than about 15 percent of the pipe diameter (Fig. 6-13b), the turbulent flow loss coefficient  $K$  is only about 0.1 (Vennard and Street, *Elementary Fluid Mechanics*, 5th ed., Wiley, New York, 1975, pp. 420–421). Rounding of the inlet prevents formation of the **vena contracta**, thereby reducing the resistance to flow.

For **laminar flow** the losses in sudden contraction may be estimated for area ratios  $A_2/A_1 < 0.2$  by an equivalent additional pipe length  $L_e$  given by

$$L_e/D = 0.3 + 0.04\text{Re} \tag{6-92}$$

**FIG. 6-13** Contractions and enlargements: (a) sudden contraction, (b) rounded contraction, (c) sudden enlargement, and (d) uniformly diverging duct.

where  $D$  is the diameter of the smaller pipe and  $Re$  is the Reynolds number in the smaller pipe. For laminar flow in the entrance to rectangular ducts, see Shah (*J. Fluids Eng.*, **100**, 177–179 [1978]) and Roscoe (*Philos. Mag.*, **40**, 338–351 [1949]). For creeping flow,  $Re < 1$ , of power law fluids, the entrance loss is approximately  $L_e/D = 0.3n$  (Boger, Gupta, and Tanner, *J. Non-Newtonian Fluid Mech.*, **4**, 239–248 [1978]). For viscoelastic fluid flow in circular channels with sudden contraction, a toroidal vortex forms upstream of the contraction plane. Such flows are reviewed by Boger (*Ann. Review Fluid Mech.*, **19**, 157–182 [1987]).

For creeping flow through **conical converging channels**, inertial acceleration terms are negligible and the viscous pressure drop  $\Delta p = \rho l_v$  may be computed by integration of the differential form of the Hagen-Poiseuille equation Eq. (6-36), provided the angle of convergence is small. The result for a power law fluid is

$$\Delta p = 4K \left( \frac{3n+1}{4n} \right)^n \left( \frac{8V_2}{D_2} \right)^n \left\{ \frac{1}{6n \tan(\alpha/2)} \left[ 1 - \left( \frac{D_2}{D_1} \right)^{3n} \right] \right\} \quad (6-93)$$

where  $D_1$  = inlet diameter  
 $D_2$  = exit diameter  
 $V_2$  = velocity at the exit  
 $\alpha$  = total included angle

Equation (6-93) agrees with experimental data (Kemblowski and Kiljanski, *Chem. Eng. J. (Lausanne)*, **9**, 141–151 [1975]) for  $\alpha < 11^\circ$ . For Newtonian liquids, Eq. (6-93) simplifies to

$$\Delta p = \mu \left( \frac{32V_2}{D_2} \right) \left\{ \frac{1}{6 \tan(\alpha/2)} \left[ 1 - \left( \frac{D_2}{D_1} \right)^3 \right] \right\} \quad (6-94)$$

For creeping flow through noncircular converging channels, the differential form of the Hagen-Poiseuille equation with equivalent diameter given by Eqs. (6-50) to (6-52) may be used, provided the convergence is gradual.

**Expansion and Exit Losses** For ducts of any cross section, the frictional loss for a **sudden enlargement** (Fig. 6-13c) with turbulent flow is given by the Borda-Carnot equation:

$$l_v = \frac{V_1^2 - V_2^2}{2} = \frac{V_1^2}{2} \left( 1 - \frac{A_1}{A_2} \right)^2 \quad (6-95)$$

where  $V_1$  = velocity in the smaller duct  
 $V_2$  = velocity in the larger duct  
 $A_1$  = cross-sectional area of the smaller duct  
 $A_2$  = cross-sectional area of the larger duct

Equation (6-95) is valid for incompressible flow. For compressible flows, see Benedict, Wyler, Dudek, and Glead (*J. Eng. Power*, **98**, 327–334 [1976]). For an infinite expansion,  $A_1/A_2 = 0$ , Eq. (6-95) shows that the **exit loss** from a pipe is 1 velocity head. This result is easily deduced from the mechanical energy balance Eq. (6-90), noting that  $p_1 = p_2$ . This exit loss is due to the dissipation of the discharged jet; there is no pressure drop at the exit.

For creeping Newtonian flow ( $Re < 1$ ), the frictional loss due to a sudden enlargement should be obtained from the same equation for a sudden contraction (Eq. [6-92]). Note, however, that Boger, Gupta, and Tanner (*ibid.*) give an exit friction equivalent length of 0.12 diameter, increasing for power law fluids as the exponent decreases. For laminar flows at higher Reynolds numbers, the pressure drop is twice that given by Eq. (6-95). This results from the velocity profile factor  $\alpha$  in the mechanical energy balance being 2.0 for the parabolic laminar velocity profile.

If the transition from a small to a large duct of any cross-sectional shape is accomplished by a **uniformly diverging duct** (see Fig. 6-13d) with a straight axis, the total frictional pressure drop can be computed by integrating the differential form of Eq. (6-89),  $dl_v/dx = 2fV^2/D$  over the length of the expansion, provided the total angle  $\alpha$  between the diverging walls is less than  $7^\circ$ . For angles between  $7^\circ$  and  $45^\circ$ , the loss coefficient may be estimated as 2.6  $\sin(\alpha/2)$  times the loss coefficient for a sudden expansion; see Hooper (*Chem. Eng.*, Nov. 7, 1988). Gibson (*Hydraulics and Its Applications*, 5th ed., Constable, London 1952, p. 93) recommends multiplying the sudden enlargement loss by 0.13 for  $5^\circ < \alpha < 7.5^\circ$  and by  $0.0110\alpha^{1.22}$  for  $7.5^\circ < \alpha <$

$35^\circ$ . For angles greater than  $35^\circ$  to  $45^\circ$ , the losses are normally considered equal to those for a sudden expansion, although in some cases the losses may be greater. Expanding flow through standard pipe reducers should be treated as sudden expansions.

**Trumpet-shaped enlargements for turbulent flow** designed for constant decrease in velocity head per unit length were found by Gibson (*ibid.*, p. 95) to give 20 to 60 percent less frictional loss than straight taper pipes of the same length.

A special feature of expansion flows occurs when **viscoelastic** liquids are extruded through a die at a low Reynolds number. The extrudate may expand to a diameter several times greater than the die diameter, whereas for a Newtonian fluid the diameter expands only 10 percent. This phenomenon, called **die swell**, is most pronounced with short dies (Graessley, Glasscock, and Crawley, *Trans. Soc. Rheol.*, **14**, 519–544 [1970]). For velocity distribution measurements near the die exit, see Goulden and MacSporran (*J. Non-Newtonian Fluid Mech.*, **1**, 183–198 [1976]) and Whipple and Hill (*AIChE J.*, **24**, 664–671 [1978]). At high flow rates, the extrudate becomes distorted, suffering **melt fracture** at wall shear stresses greater than  $10^5$  N/m<sup>2</sup>. This phenomenon is reviewed by Denn (*Ann. Review Fluid Mech.*, **22**, 13–34 [1990]). Ramamurthy (*J. Rheol.*, **30**, 337–357 [1986]) has found a dependence of apparent stick-slip behavior in melt fracture to be dependent on the material of construction of the die.

**Fittings and Valves** For **turbulent flow**, the frictional loss for fittings and valves can be expressed by the equivalent length or velocity head methods. As fitting size is varied,  $K$  values are relatively more constant than  $L_e/D$  values, but since fittings generally do not achieve geometric similarity between sizes,  $K$  values tend to decrease with increasing fitting size. Table 6-4 gives  $K$  values for many types of fittings and valves.

Manufacturers of valves, especially control valves, express valve capacity in terms of a flow coefficient  $C_v$ , which gives the flow rate through the valve in gal/min of water at 60°F under a pressure drop of 1 lbf/in<sup>2</sup>. It is related to  $K$  by

$$C_v = \frac{C_1 d^2}{\sqrt{K}} \quad (6-96)$$

where  $C_1$  is a dimensional constant equal to 29.9 and  $d$  is the diameter of the valve connections in inches.

For **laminar flow**, data for the frictional loss of valves and fittings are meager (Beck and Miller, *J. Am. Soc. Nav. Eng.*, **56**, 62–83 [1944]; Beck, *ibid.*, **56**, 235–271, 366–388, 389–395 [1944]; De Craene, *Heat. Piping Air Cond.*, **27**[10], 90–95 [1955]; Karr and Schutz, *J. Am. Soc. Nav. Eng.*, **52**, 239–256 [1940]; and Kittredge and Rowley, *Trans. ASME*, **79**, 1759–1766 [1957]). The data of Kittredge and Rowley indicate that  $K$  is constant for Reynolds numbers above 500 to 2,000, but increases rapidly as  $Re$  decreases below 500. Typical values for  $K$  for laminar flow Reynolds numbers are shown in Table 6-5.

Methods to calculate losses for **tee and wye junctions** for dividing and combining flow are given by Miller (*Internal Flow Systems*, 2d ed., Chap. 13, BHRA, Cranfield, 1990), including effects of Reynolds number, angle between legs, area ratio, and radius. Junctions with more than three legs are also discussed. The sources of data for the loss coefficient charts are Blaisdell and Manson (*U.S. Dept. Agric. Res. Serv. Tech. Bull.* 1283 [August 1963]) for combining flow and Gardel (*Bull. Tech. Suisses Romande*, **85**[9], 123–130 [1957]; **85**[10], 143–148 [1957]) together with additional unpublished data for dividing flow.

Miller (*Internal Flow Systems*, 2d ed., Chap. 13, BHRA, Cranfield, 1990) gives the most complete information on losses in **bends and curved pipes**. For turbulent flow in circular cross-section bends of constant area, as shown in Fig. 6-14a, a more accurate estimate of the loss coefficient  $K$  than that given in Table 6-4 is

$$K = K^\circ C_{Re} C_o C_f \quad (6-97)$$

where  $K^\circ$ , given in Fig. 6-14b, is the loss coefficient for a smooth-walled bend at a Reynolds number of  $10^6$ . The Reynolds number correction factor  $C_{Re}$  is given in Fig. 6-14c. For  $0.7 < r/D < 1$  or for  $K^\circ < 0.4$ , use the  $C_{Re}$  value for  $r/D = 1$ . Otherwise, if  $r/D < 1$ , obtain  $C_{Re}$  from

$$C_{Re} = \frac{K^\circ}{K^\circ + 0.2(1 - C_{Re, r/D=1})} \quad (6-98)$$

**TABLE 6-4 Additional Frictional Loss for Turbulent Flow through Fittings and Valves<sup>a</sup>**

| Type of fitting or valve                                  | Additional friction loss, equivalent no. of velocity heads, K |

SOURCE: From curves by Kirtledge and Rowley, *Trans. Am. Soc. Mech. Eng.*, **79**, 1759–1766 (1957).

The correction  $C_o$  (Fig. 6-14d) accounts for the extra losses due to developing flow in the outlet tangent of the pipe, of length  $L_o$ . The total loss for the bend plus outlet pipe includes the bend loss  $K$  plus the straight pipe frictional loss in the outlet pipe  $4fL_o/D$ . Note that  $C_o = 1$  for  $L_o/D$  greater than the termination of the curves on Fig. 6-14d, which indicate the distance at which fully developed flow in the outlet pipe is reached. Finally, the roughness correction is

$$C_f = \frac{f_{\text{rough}}}{f_{\text{smooth}}} \quad (6-99)$$

where  $f_{\text{rough}}$  is the friction factor for a pipe of diameter  $D$  with the roughness of the bend, at the bend inlet Reynolds number. Similarly,  $f_{\text{smooth}}$  is the friction factor for smooth pipe. For  $Re > 10^6$  and  $r/D \geq 1$ , use the value of  $C_f$  for  $Re = 10^6$ .

**Example 6: Losses with Fittings and Valves** It is desired to calculate the liquid level in the vessel shown in Fig. 6-15 required to produce a discharge velocity of 2 m/s. The fluid is water at 20°C with  $\rho = 1,000 \text{ kg/m}^3$  and  $\mu = 0.001 \text{ Pa} \cdot \text{s}$ , and the butterfly valve is at  $\theta = 10^\circ$ . The pipe is 2-in Schedule 40, with an inner diameter of 0.0525 m. The pipe roughness is 0.046 mm. Assuming the flow is turbulent and taking the velocity profile factor  $\alpha = 1$ , the engineering Bernoulli equation Eq. (6-16), written between surfaces 1 and 2, where the pressures are both atmospheric and the fluid velocities are 0 and  $V = 2 \text{ m/s}$ , respectively, and there is no shaft work, simplifies to

$$gZ = \frac{V^2}{2} + l_e$$

Contributing to  $l_e$  are losses for the entrance to the pipe, the three sections of straight pipe, the butterfly valve, and the 90° bend. Note that no exit loss is used because the discharged jet is outside the control volume. Instead, the  $V^2/2$  term accounts for the kinetic energy of the discharging stream. The Reynolds number in the pipe is

$$Re = \frac{DV\rho}{\mu} = \frac{0.0525 \times 2 \times 1000}{0.001} = 1.05 \times 10^5$$

From Fig. 6-9 or Eq. (6-38), at  $\epsilon/D = 0.046 \times 10^{-3}/0.0525 = 0.00088$ , the friction factor is about 0.0054. The straight pipe losses are then

$$\begin{aligned} l_{e(\text{sp})} &= \left( \frac{4fL}{D} \right) \frac{V^2}{2} \\ &= \left( \frac{4 \times 0.0054 \times (1 + 1 + 1)}{0.0525} \right) \frac{V^2}{2} \\ &= 1.23 \frac{V^2}{2} \end{aligned}$$

The losses from Table 6-4 in terms of velocity heads  $K$  are  $K = 0.5$  for the sudden contraction and  $K = 0.52$  for the butterfly valve. For the 90° standard radius ( $r/D = 1$ ), the table gives  $K = 0.75$ . The method of Eq. (6-94), using Fig. 6-14, gives

$$\begin{aligned} K &= K^* C_{\text{re}} C_o C_f \\ &= 0.24 \times 1.24 \times 1.0 \times \left( \frac{0.0054}{0.0044} \right) \\ &= 0.37 \end{aligned}$$

This value is more accurate than the value in Table 6-4. The value  $f_{\text{smooth}} = 0.0044$  is obtainable either from Eq. (6-37) or Fig. 6-9.

The total losses are then

$$l_e = (1.23 + 0.5 + 0.52 + 0.37) \frac{V^2}{2} = 2.62 \frac{V^2}{2}$$

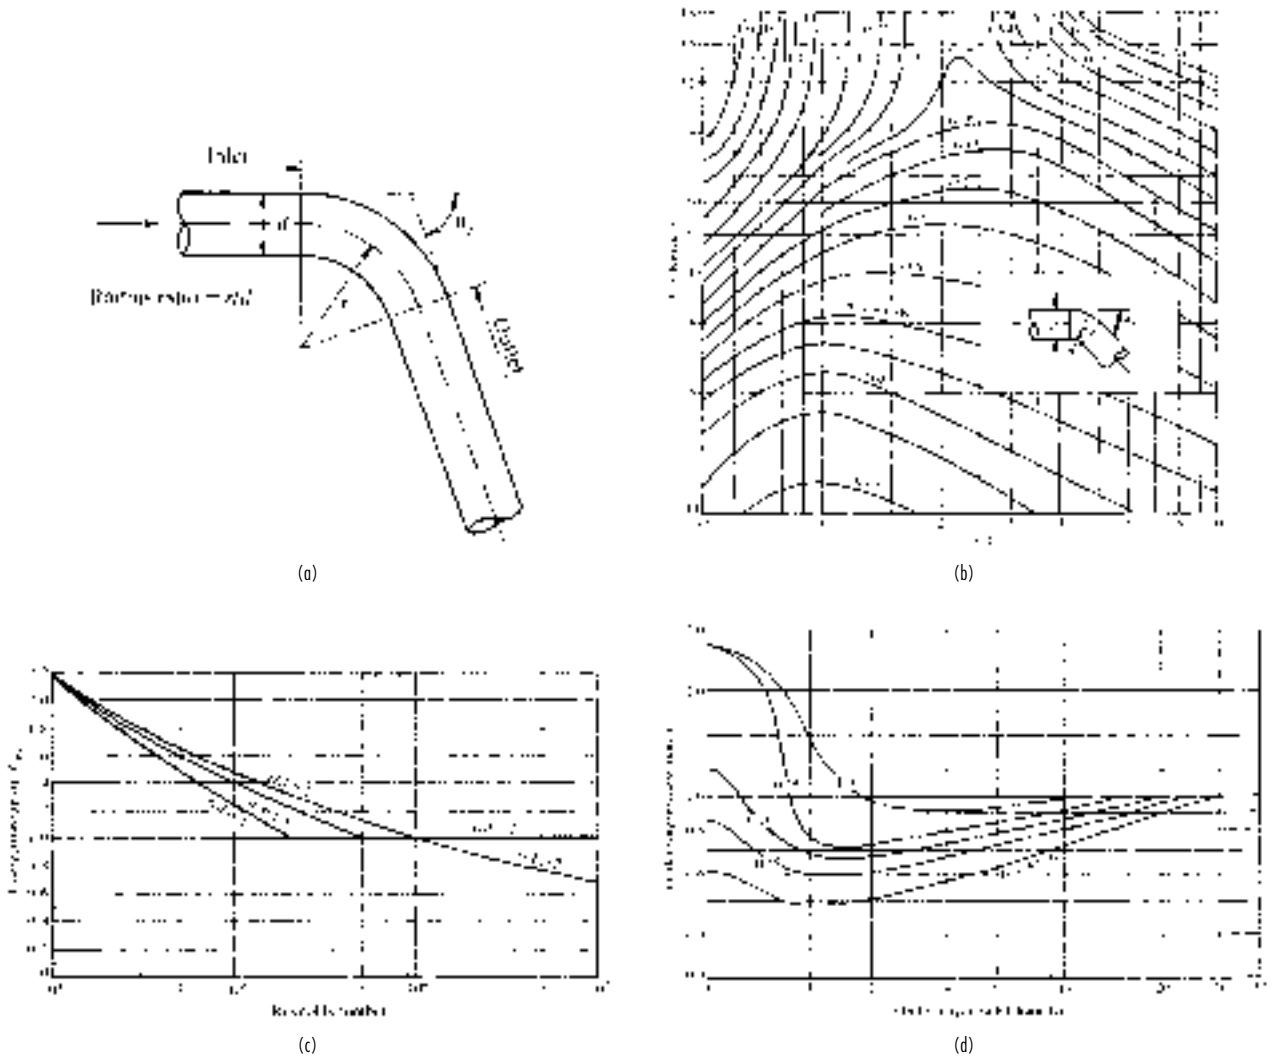

FIG. 6-14 Loss coefficients for flow in bends and curved pipes: (a) flow geometry, (b) loss coefficient for a smooth-walled bend at  $Re = 10^6$ , (c)  $Re$  correction factor, (d) outlet pipe correction factor. (From D. S. Miller; Internal Flow Systems, 2d ed., BHRA, Cranfield, U.K., 1990.)

and the liquid level  $Z$  is

$$Z = \frac{1}{g} \left( \frac{V^2}{2} + 2.62 \frac{V^2}{2} \right) = 3.62 \frac{V^2}{2g}$$

$$= \frac{3.62 \times 2^2}{2 \times 9.81} = 0.73 \text{ m}$$

FIG. 6-15 Tank discharge example.

**Curved Pipes and Coils** For flow through curved pipe or coil, a secondary circulation perpendicular to the main flow called the **Dean effect** occurs. This circulation increases the friction relative to straight pipe flow and stabilizes laminar flow, delaying the transition Reynolds number to about

$$Re_{crit} = 2,100 \left( 1 + 12 \sqrt{\frac{D}{D_c}} \right) \quad (6-100)$$

where  $D_c$  is the coil diameter. Equation (6-100) is valid for  $10 < D_c/D < 250$ . The **Dean number** is defined as

$$De = \frac{Re}{(D_c/D)^{1/2}} \quad (6-101)$$

In laminar flow, the friction factor for curved pipe  $f_c$  may be expressed in terms of the straight pipe friction factor  $f = 16/Re$  as (Hart, *Chem. Eng. Sci.*, **43**, 775-783 [1988])

$$f_c/f = 1 + 0.090 \left( \frac{De^{1.5}}{70 + De} \right) \quad (6-102)$$

## 6-20 FLUID AND PARTICLE DYNAMICS

For turbulent flow, equations by Ito (*J. Basic Eng.*, **81**, 123 [1959]) and Srinivasan, Nandapurkar, and Holland (*Chem. Eng. [London]* no. 218, CE113-CE119 [May 1968]) may be used, with probable accuracy of  $\pm 15$  percent. Their equations are similar to

$$f_c = \frac{0.079}{\text{Re}^{0.25}} + \frac{0.0073}{\sqrt{(D_c/D)}} \quad (6-103)$$

The pressure drop for flow in **spirals** is discussed by Srinivasan, et al. (loc. cit.) and Ali and Seshadri (*Ind. Eng. Chem. Process Des. Dev.*, **10**, 328-332 [1971]). For friction loss in laminar flow through **semi-circular ducts**, see Masliyah and Nandakumar (*AIChE J.*, **25**, 478-487 [1979]); for curved channels of **square cross section**, see Cheng, Lin, and Ou (*J. Fluids Eng.*, **98**, 41-48 [1976]).

For **non-Newtonian (power law) fluids** in coiled tubes, Mashelkar and Devarajan (*Trans. Inst. Chem. Eng. (London)*, **54**, 108-114 [1976]) propose the correlation

$$f_c = (9.07 - 9.44n + 4.37n^2)(D/D_c)^{0.5}(\text{De}')^{-0.768 + 0.122n} \quad (6-104)$$

where  $\text{De}'$  is a modified Dean number given by

$$\text{De}' = \frac{1}{8} \left( \frac{6n+2}{n} \right)^n \text{Re}_{\text{MR}} \sqrt{\frac{D}{D_c}} \quad (6-105)$$

where  $\text{Re}_{\text{MR}}$  is the Metzner-Reed Reynolds number, Eq. (6-65). This correlation was tested for the range  $\text{De}' = 70$  to 400,  $D/D_c = 0.01$  to 0.135, and  $n = 0.35$  to 1. See also Oliver and Asghar (*Trans. Inst. Chem. Eng. [London]*, **53**, 181-186 [1975]).

**Screens** The pressure drop for incompressible flow across a screen of fractional free area  $\alpha$  may be computed from

$$\Delta p = K \frac{\rho V^2}{2} \quad (6-106)$$

where  $\rho$  = fluid density  
 $V$  = superficial velocity based upon the gross area of the screen  
 $K$  = velocity head loss

$$K = \left( \frac{1}{C^2} \right) \left( \frac{1 - \alpha^2}{\alpha^2} \right) \quad (6-107)$$

The discharge coefficient for the screen  $C$  with aperture  $D_s$  is given as a function of screen Reynolds number  $\text{Re} = D_s(V/\alpha)\rho/\mu$  in Fig. 6-16 for **plain square-mesh screens**,  $\alpha = 0.14$  to 0.79. This curve fits most of the data within  $\pm 20$  percent. In the laminar flow region,  $\text{Re} < 20$ , the discharge coefficient can be computed from

$$C = 0.1\sqrt{\text{Re}} \quad (6-108)$$

Coefficients greater than 1.0 in Fig. 6-16 probably indicate partial pressure recovery downstream of the minimum aperture, due to rounding of the wires.

Grootenhuis (*Proc. Inst. Mech. Eng. [London]*, **A168**, 837-846 [1954]) presents data which indicate that for a series of screens, the total pressure drop equals the number of screens times the pressure drop for one screen, and is not affected by the spacing between screens or their orientation with respect to one another, and presents a correlation for frictional losses across plain square-mesh screens and sintered gauzes. Armour and Cannon (*AIChE J.*, **14**, 415-420 [1968]) give a correlation based on a packed bed model for plain, twill, and "dutch" weaves. For losses through monofilament fabrics see Pederesen (*Filtr. Sep.*, **11**, 586-589 [1975]). For screens **inclined at an angle  $\theta$** , use the normal velocity component  $V'$

$$V' = V \cos \theta \quad (6-109)$$

(Carothers and Baines, *J. Fluids Eng.*, **97**, 116-117 [1975]) in place of  $V$  in Eq. (6-106). This applies for  $\text{Re} > 500$ ,  $C = 1.26$ ,  $\alpha \leq 0.97$ , and  $0 < \theta < 45^\circ$ , for square-mesh screens and diamond-mesh netting. Screens inclined at an angle to the flow direction also experience a tangential stress.

For **non-Newtonian** fluids in slow flow, friction loss across a square-woven or full-twill-woven screen can be estimated by considering the screen as a set of parallel tubes, each of diameter equal to the average minimal opening between adjacent wires, and length twice the diameter, without entrance effects (Carley and Smith, *Polym. Eng. Sci.*, **18**, 408-415 [1978]). For screen stacks, the losses of individual screens should be summed.

### JET BEHAVIOR

A **free jet**, upon leaving an outlet, will entrain the surrounding fluid, expand, and decelerate. To a first approximation, total momentum is conserved as jet momentum is transferred to the entrained fluid. For practical purposes, a jet is considered free when its cross-sectional area is less than one-fifth of the total cross-sectional flow area of the region through which the jet is flowing (Elrod, *Heat. Piping Air Cond.*, **26**[3], 149-155 [1954]), and the surrounding fluid is the same as the jet fluid. A **turbulent jet** in this discussion is considered to be a free jet with Reynolds number greater than 2,000. Additional discussion on the relation between Reynolds number and turbulence in jets is given by Elrod (ibid.). Abramowicz (*The Theory of Turbulent Jets*, MIT Press, Cambridge, 1963) and Rajaratnam (*Turbulent Jets*, Elsevier, Amsterdam, 1976) provide thorough discourses on turbulent jets. Hussein, et al. (*J. Fluid Mech.*, **258**, 31-75 [1994]) give extensive

FIG. 6-16 Screen discharge coefficients, plain square-mesh screens. (Courtesy of E. I. du Pont de Nemours & Co.)

FIG. 6-17 Configuration of a turbulent free jet.

velocity data for a free jet, as well as an extensive discussion of free jet experimentation and comparison of data with momentum conservation equations.

A turbulent free jet is normally considered to consist of four flow regions (Tuve, *Heat. Piping Air Cond.*, **25**[1], 181–191 [1953]; Davies, *Turbulence Phenomena*, Academic, New York, 1972) as shown in Fig. 6-17:

1. Region of flow establishment—a short region whose length is about 6.4 nozzle diameters. The fluid in the conical core of the same length has a velocity about the same as the initial discharge velocity. The termination of this *potential core* occurs when the growing mixing or boundary layer between the jet and the surroundings reaches the centerline of the jet.
2. A transition region that extends to about 8 nozzle diameters.
3. Region of established flow—the principal region of the jet. In this region, the velocity profile transverse to the jet is self-preserving when normalized by the centerline velocity.
4. A terminal region where the residual centerline velocity reduces rapidly within a short distance. For air jets, the residual velocity will reduce to less than 0.3 m/s, (1.0 ft/s) usually considered still air.

Several references quote a length of 100 nozzle diameters for the length of the established flow region. However, this length is dependent on initial velocity and Reynolds number.

Table 6-6 gives characteristics of **rounded-inlet circular jets** and **rounded-inlet infinitely wide slot jets** (aspect ratio > 15). The information in the table is for a homogeneous, incompressible air system under isothermal conditions. The table uses the following nomenclature:

- $B_0$  = slot height
- $D_0$  = circular nozzle opening
- $q$  = total jet flow at distance  $x$
- $q_0$  = initial jet flow rate
- $r$  = radius from circular jet centerline
- $y$  = transverse distance from slot jet centerline
- $V_c$  = centerline velocity
- $V_r$  = circular jet velocity at  $r$
- $V_y$  = velocity at  $y$

Witze (*Am. Inst. Aeronaut. Astronaut. J.*, **12**, 417–418 [1974]) gives equations for the centerline velocity decay of different types of subsonic and supersonic circular free jets. Entrainment of surrounding fluid in the region of flow establishment is lower than in the region of established flow (see Hill, *J. Fluid Mech.*, **51**, 773–779 [1972]). Data of Donald and Singer (*Trans. Inst. Chem. Eng. [London]*, **37**, 255–267 [1959]) indicate that jet angle and the coefficients given in Table 6-6 depend upon the fluids; for a water system, the jet angle for a circular jet is 14° and the entrainment ratio is about 70 percent of that for an air system. Most likely these variations are due to Reynolds number effects which are not taken into account in Table 6-6. Rushton (*AIChE J.*, **26**, 1038–1041 [1980]) examined available published results for circular jets and found that the centerline velocity decay is given by

$$\frac{V_c}{V_0} = 1.41Re^{0.135} \left( \frac{D_0}{x} \right) \quad (6-110)$$

where  $Re = D_0V_0\rho/\mu$  is the initial jet Reynolds number. This result corresponds to a jet angle  $\tan \alpha/2$  proportional to  $Re^{-0.135}$ .

TABLE 6-6 Turbulent Free-Jet Characteristics

Where both jet fluid and entrained fluid are air

| Rounded-inlet circular jet  |  |
|---|--|
| Longitudinal distribution of velocity along jet center line <sup>a†</sup> |  |
| $\frac{V_c}{V_0} = K \frac{D_0}{x}$                                       | for $7 < \frac{x}{D_0} < 100$                              |
| $K = 5$   | for $V_0 = 2.5$ to $5.0$ m/s                               |
| $K = 6.2$   | for $V_0 = 10$ to $50$ m/s                                 |
| Radial distribution of longitudinal velocity <sup>†</sup>                 |  |
| $\log \left( \frac{V_c}{V_r} \right) = 40 \left( \frac{r}{x} \right)^2$   | for $7 < \frac{x}{D_0} < 100$                              |
| Jet angle <sup>o†</sup>   |  |
| $\alpha \approx 20^\circ$   | for $\frac{x}{D_0} < 100$                                  |
| Entrainment of surrounding fluid <sup>‡</sup>                             |  |
| $\frac{q}{q_0} = 0.32 \frac{x}{D_0}$                                      | for $7 < \frac{x}{D_0} < 100$                              |
| Rounded-inlet, infinitely wide slot jet                                   |  |
| Longitudinal distribution of velocity along jet centerline <sup>‡</sup>   |  |
| $\frac{V_c}{V_0} = 2.28 \left( \frac{B_0}{x} \right)^{0.5}$               | for $5 < \frac{x}{B_0} < 2,000$ and $V_0 = 12$ to $55$ m/s |
| Transverse distribution of longitudinal velocity <sup>‡</sup>             |  |
| $\log \left( \frac{V_c}{V_x} \right) = 18.4 \left( \frac{y}{x} \right)^2$ | for $5 < \frac{x}{B_0} < 2,000$                            |
| Jet angle <sup>‡</sup>  |  |
| $\alpha$ is slightly larger than that for a circular jet                  |  |

| $\frac{q}{q_0} = 0.62 \left( \frac{x}{B_0} \right)^{0.5}$                 | for $5 < \frac{x}{B_0} < 2,000$                            |

<sup>a</sup>Nottage, Slaby, and Gojsza, *Heat. Piping Air Cond.*, **24**(1), 165–176 (1952).

<sup>†</sup>Tuve, *Heat. Piping Air Cond.*, **25**(1), 181–191 (1953).

<sup>‡</sup>Albertson, Dai, Jensen, and Rouse, *Trans. Am. Soc. Civ. Eng.*, **115**, 639–664 (1950), and Discussion, *ibid.*, **115**, 665–697 (1950).

Characteristics of **rectangular jets** of various aspect ratios are given by Elrod (*Heat., Piping, Air Cond.*, **26**[3], 149–155 [1954]). For **slot jets discharging into a moving fluid**, see Weinstein, Osterle, and Forstall (*J. Appl. Mech.*, **23**, 437–443 [1967]). **Coaxial jets** are discussed by Forstall and Shapiro (*J. Appl. Mech.*, **17**, 399–408 [1950]), and **double concentric jets** by Chigier and Beer (*J. Basic Eng.*, **86**, 797–804 [1964]). **Axisymmetric confined jets** are described by Barchilon and Curtet (*J. Basic Eng.*, **777–787** [1964]). **Restrained** turbulent jets of liquid discharging into air are described by Davies (*Turbulence Phenomena*, Academic, New York, 1972). These jets are inherently unstable and break up into drops after some distance. Lienhard and Day (*J. Basic Eng. Trans. AIME*, p. 515 [September 1970]) discuss the breakup of superheated liquid jets which flash upon discharge.

**Density gradients** affect the spread of a single-phase jet. A jet of lower density than the surroundings spreads more rapidly than a jet of the same density as the surroundings, and, conversely, a denser jet spreads less rapidly. Additional details are given by Keagy and Weller (*Proc. Heat Transfer Fluid Mech. Inst., ASME*, pp. 89–98, June 22–24 [1949]) and Cleaves and Boelter (*Chem. Eng. Prog.*, **43**, 123–134 [1947]).

Few experimental data exist on **laminar jets** (see Gutfinger and Shinnar, *AIChE J.*, **10**, 631–639 [1964]). Theoretical analysis for velocity distributions and entrainment ratios are available in Schlichting and in Morton (*Phys. Fluids*, **10**, 2120–2127 [1967]).

Theoretical analyses of jet flows for power law **non-Newtonian fluids** are given by Vlachopoulos and Stournaras (*AIChE J.*, **21**, 385–388 [1975]), Mitwally (*J. Fluids Eng.*, **100**, 363 [1978]), and Sridhar and Rankin (*J. Fluids Eng.*, **100**, 500 [1978]).

FIG. 6-18 Flow through an orifice.

### FLOW THROUGH ORIFICES

Section 10 of this *Handbook* describes the use of orifice meters for flow measurement. In addition, **orifices** are commonly found within pipelines as flow-restricting devices, in perforated pipe distributing and return manifolds, and in perforated plates. Incompressible flow through an orifice in a pipeline, as shown in Fig. 6-18, is commonly described by the following equation for flow rate  $Q$  in terms of the pressures  $P_1$ ,  $P_2$ , and  $P_3$ ; the orifice area  $A_o$ ; the pipe cross-sectional area  $A$ ; and the density  $\rho$ .

$$\begin{aligned} Q &= v_o A_o = C_o A_o \sqrt{\frac{2(P_1 - P_2)}{\rho[1 - (A_o/A)^2]}} \\ &= C_o A_o \sqrt{\frac{2(P_1 - P_3)}{\rho(1 - A_o/A)[1 - (A_o/A)^2]}} \end{aligned} \quad (6-111)$$

The velocity based on the hole area is  $v_o$ . The pressure  $P_1$  is the pressure upstream of the orifice, typically about 1 pipe diameter upstream, the pressure  $P_2$  is the pressure at the **vena contracta**, where the flow passes through a minimum area which is less than the orifice area, and the pressure  $P_3$  is the pressure downstream of the vena contracta after pressure recovery associated with deceleration of the fluid. The velocity of approach factor  $1 - (A_o/A)^2$  accounts for the kinetic energy approaching the orifice, and the **orifice coefficient** or **discharge coefficient**  $C_o$  accounts for the vena contracta. The location of the vena contracta varies with  $A_o/A$ , but is about 0.7 pipe diameter for  $A_o/A < 0.25$ . The factor  $1 - A_o/A$  accounts for pressure recovery. Pressure recovery is complete by about 4 to 8 pipe diameters downstream of the orifice. The permanent pressure drop is  $P_1 - P_3$ . When the orifice is at the end of pipe, discharging directly into a large chamber, there is negligible pressure recovery, the permanent pressure drop is  $P_1 - P_2$ , and the last equality in Eq. (6-111) does not apply. Instead,  $P_2 = P_3$ . Equation (6-111) may also be used for flow across a perforated plate with open area  $A_o$  and total area  $A$ . The location of the vena contracta and complete recovery would scale not with the vessel or pipe diameter in which the plate is installed, but with the hole diameter and pitch between holes.

The orifice coefficient has a value of about 0.62 at large Reynolds numbers ( $Re = D_o V_o \rho / \mu > 20,000$ ), although values ranging from 0.60 to 0.70 are frequently used. At lower Reynolds numbers, the orifice coefficient varies with both  $Re$  and with the area or diameter ratio. See Sec. 10 for more details.

When liquids discharge vertically downward from a pipe of diameter  $D_p$ , through orifices into gas, gravity increases the discharge coefficient. Figure 6-19 shows this effect, giving the discharge coefficient in terms of a modified Froude number,  $Fr = \Delta p / (\rho g D_p)$ .

The orifice coefficient deviates from its value for sharp-edged orifices when the orifice wall thickness exceeds about 75 percent of the orifice diameter. Some pressure recovery occurs within the orifice and the orifice coefficient increases. Pressure drop across **segmental orifices** is roughly 10 percent greater than that for concentric circular orifices of the same open area.

### COMPRESSIBLE FLOW

Flows are typically considered **compressible** when the density varies by more than 5 to 10 percent. In practice compressible flows are normally limited to gases, supercritical fluids, and multiphase flows

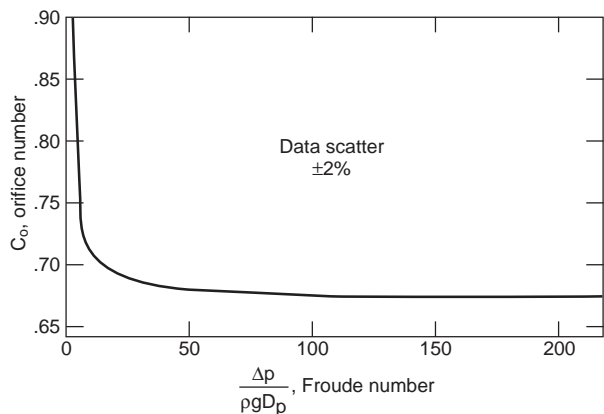

FIG. 6-19 Orifice coefficient vs. Froude number. (Courtesy E. I. duPont de Nemours &amp; Co.)

containing gases. Liquid flows are normally considered incompressible, except for certain calculations involved in **hydraulic transient** analysis (see following) where compressibility effects are important even for nearly incompressible liquids with extremely small density variations. Textbooks on compressible gas flow include Shapiro (*Dynamics and Thermodynamics of Compressible Fluid Flow*, vols. I and II, Ronald Press, New York [1953]) and Zucrow and Hoffman (*Gas Dynamics*, vols. I and II, Wiley, New York [1976]).

In chemical process applications, one-dimensional gas flows through nozzles or orifices and in pipelines are the most important applications of compressible flow. Multidimensional external flows are of interest mainly in aerodynamic applications.

**Mach Number and Speed of Sound** The **Mach number**  $M = V/c$  is the ratio of fluid velocity,  $V$ , to the **speed of sound** or **acoustic velocity**,  $c$ . The speed of sound is the propagation velocity of infinitesimal pressure disturbances and is derived from a momentum balance. The compression caused by the pressure wave is adiabatic and frictionless, and therefore isentropic.

$$c = \sqrt{\left(\frac{\partial p}{\partial \rho}\right)_s} \quad (6-112)$$

The derivative of pressure  $p$  with respect to density  $\rho$  is taken at constant entropy  $s$ . For an ideal gas,

$$\left(\frac{\partial p}{\partial \rho}\right)_s = \frac{kRT}{M_w}$$

where  $k$  = ratio of specific heats,  $C_p/C_v$   
 $R$  = universal gas constant (8,314 J/kgmol K)  
 $T$  = absolute temperature  
 $M_w$  = molecular weight

Hence for an ideal gas,

$$c = \sqrt{\frac{kRT}{M_w}} \quad (6-113)$$

Most often, the Mach number is calculated using the speed of sound evaluated at the local pressure and temperature. When  $M = 1$ , the flow is **critical** or **sonic** and the velocity equals the local speed of sound. For **subsonic** flow  $M < 1$  while **supersonic** flows have  $M > 1$ . Compressibility effects are important when the Mach number exceeds 0.1 to 0.2. A common error is to assume that compressibility effects are always negligible when the Mach number is small. The proper assessment of whether compressibility is important should be based on relative density changes, not on Mach number.

**Isothermal Gas Flow in Pipes and Channels** Isothermal compressible flow is often encountered in long transport lines, where there is sufficient heat transfer to maintain constant temperature. Velocities and Mach numbers are usually small, yet compressibility

effects are important when the total pressure drop is a large fraction of the absolute pressure. For an ideal gas with  $\rho = pM_w/RT$ , integration of the differential form of the momentum or mechanical energy balance equations, assuming a constant friction factor  $f$  over a length  $L$  of a channel of constant cross section and hydraulic diameter  $D_H$ , yields,

$$p_1^2 - p_2^2 = G^2 \frac{RT}{M_w} \left[ \frac{4fL}{D_H} + 2 \ln \left( \frac{p_1}{p_2} \right) \right] \quad (6-114)$$

where the mass velocity  $G = w/A = \rho V$  is the mass flow rate per unit cross-sectional area of the channel. The logarithmic term on the right-hand side accounts for the pressure change caused by acceleration of gas as its density decreases, while the first term is equivalent to the calculation of frictional losses using the density evaluated at the average pressure  $(p_1 + p_2)/2$ .

Solution of Eq. (6-114) for  $G$  and differentiation with respect to  $p_2$  reveals a maximum mass flux  $G_{\max} = p_2 \sqrt{M_w/(RT)}$  and a corresponding exit velocity  $V_{2,\max} = \sqrt{RT/M_w}$  and exit Mach number  $M_2 = 1/\sqrt{k}$ . This apparent **choking** condition, though often cited, is not physically meaningful for isothermal flow because at such high velocities, and high rates of expansion, isothermal conditions are not maintained.

**Adiabatic Frictionless Nozzle Flow** In process plant pipelines, compressible flows are usually more nearly adiabatic than isothermal. Solutions for adiabatic flows through frictionless nozzles and in channels with constant cross section and constant friction factor are readily available.

Figure 6-20 illustrates adiabatic discharge of a **perfect** gas through a frictionless nozzle from a large chamber where velocity is effectively zero. A perfect gas obeys the ideal gas law  $\rho = pM_w/RT$  and also has constant specific heat. The subscript 0 refers to the **stagnation** conditions in the chamber. More generally, stagnation conditions refer to the conditions which would be obtained by isentropically decelerating a gas flow to zero velocity. The minimum area section, or **throat**, of the nozzle is at the nozzle exit. The flow through the nozzle is isentropic because it is frictionless (reversible) and adiabatic. In terms of the exit Mach number  $M_1$  and the upstream stagnation conditions, the flow conditions at the nozzle exit are given by

$$\frac{p_0}{p_1} = \left( 1 + \frac{k-1}{2} M_1^2 \right)^{k/(k-1)} \quad (6-115)$$

$$\frac{T_0}{T_1} = 1 + \frac{k-1}{2} M_1^2 \quad (6-116)$$

$$\frac{\rho_0}{\rho_1} = \left( 1 + \frac{k-1}{2} M_1^2 \right)^{1/(k-1)} \quad (6-117)$$

The mass velocity  $G = w/A$ , where  $w$  is the mass flow rate and  $A$  is the nozzle exit area, at the nozzle exit is given by

$$G = p_0 \sqrt{\frac{kM_w}{RT_0}} \frac{M_1}{\left( 1 + \frac{k-1}{2} M_1^2 \right)^{(k+1)/2(k-1)}} \quad (6-118)$$

These equations are consistent with the isentropic relations for a per-

FIG. 6-20 Isentropic flow through a nozzle.

fect gas  $p/p_0 = (\rho/\rho_0)^k$ ,  $T/T_0 = (p/p_0)^{(k-1)/k}$ . Equation (6-116) is valid for adiabatic flows with or without friction; it does not require isentropic flow. However, Eqs. (6-115) and (6-117) do require isentropic flow.

**The exit Mach number  $M_1$  may not exceed unity.** At  $M_1 = 1$ , the flow is said to be **choked**, **sonic**, or **critical**. When the flow is choked, the pressure at the exit is greater than the pressure of the surroundings into which the gas flow discharges. The pressure drops from the exit pressure to the pressure of the surroundings in a series of shocks which are highly nonisentropic. Sonic flow conditions are denoted by  $^*$ ; sonic exit conditions are found by substituting  $M_1 = M_1^* = 1$  into Eqs. (6-115) to (6-118).

$$\frac{p^*}{p_0} = \left( \frac{2}{k+1} \right)^{k/(k-1)} \quad (6-119)$$

$$\frac{T^*}{T_0} = \frac{2}{k+1} \quad (6-120)$$

$$\frac{\rho^*}{\rho_0} = \left( \frac{2}{k+1} \right)^{1/(k-1)} \quad (6-121)$$

$$G^* = p_0 \sqrt{\left( \frac{2}{k+1} \right)^{(k+1)/(k-1)} \left( \frac{kM_w}{RT_0} \right)} \quad (6-122)$$

Note that under choked conditions, the exit velocity is  $V = V^* = c^* = \sqrt{kRT^*/M_w}$ , not  $\sqrt{kRT_0/M_w}$ . Sonic velocity must be evaluated at the exit temperature. For air, with  $k = 1.4$ , the critical pressure ratio  $p^*/p_0$  is 0.5285 and the critical temperature ratio  $T^*/T_0 = 0.8333$ . Thus, for air discharging from 300 K, the temperature drops by 50 K (90 R). This large temperature decrease results from the conversion of internal energy into kinetic energy and is reversible. As the discharged jet decelerates in the external stagnant gas, it recovers its initial enthalpy.

When it is desired to determine the discharge rate through a nozzle from upstream pressure  $p_0$  to external pressure  $p_2$ , Equations (6-115) through (6-122) are best used as follows. The critical pressure is first determined from Eq. (6-119). If  $p_2 > p^*$ , then the flow is subsonic (subcritical, unchoked). Then  $p_1 = p_2$  and  $M_1$  may be obtained from Eq. (6-115). Substitution of  $M_1$  into Eq. (6-118) then gives the desired mass velocity  $G$ . Equations (6-116) and (6-117) may be used to find the exit temperature and density. On the other hand, if  $p_2 \leq p^*$ , then the flow is choked and  $M_1 = 1$ . Then  $p_1 = p^*$ , and the mass velocity is  $G^*$  obtained from Eq. (6-122). The exit temperature and density may be obtained from Eqs. (6-120) and (6-121).

When the flow is choked,  $G = G^*$  is independent of external downstream pressure. Reducing the downstream pressure will not increase the flow. The mass flow rate under choking conditions is directly proportional to the upstream pressure.

**Example 7: Flow through Frictionless Nozzle** Air at  $p_0$  and temperature  $T_0 = 293$  K discharges through a frictionless nozzle to atmospheric pressure. Compute the discharge mass flux  $G$ , the pressure, temperature, Mach number, and velocity at the exit. Consider two cases: (1)  $p_0 = 7 \times 10^5$  Pa absolute, and (2)  $p_0 = 1.5 \times 10^5$  Pa absolute.

1.  $p_0 = 7.0 \times 10^5$  Pa. For air with  $k = 1.4$ , the critical pressure ratio from Eq. (6-119) is  $p^*/p_0 = 0.5285$  and  $p^* = 0.5285 \times 7.0 \times 10^5 = 3.70 \times 10^5$  Pa. Since this is greater than the external atmospheric pressure  $p_2 = 1.01 \times 10^5$  Pa, the flow is choked and the exit pressure is  $p_1 = 3.70 \times 10^5$  Pa. The exit Mach number is 1.0, and the mass flux is equal to  $G^*$  given by Eq. (6-118).

$$G^* = 7.0 \times 10^5 \times \sqrt{\left( \frac{2}{1.4+1} \right)^{(1.4+1)/(1.4-1)} \left( \frac{1.4 \times 29}{8314 \times 293} \right)} = 1,650 \text{ kg/m}^2 \cdot \text{s}$$

The exit temperature, since the flow is choked, is

$$T^* = \left( \frac{T^*}{T_0} \right) T_0 = \left( \frac{2}{1.4+1} \right) \times 293 = 244 \text{ K}$$

The exit velocity is  $V = Mc = c^* = \sqrt{kRT^*/M_w} = 313$  m/s.

2.  $p_0 = 1.5 \times 10^5$  Pa. In this case  $p^* = 0.79 \times 10^5$  Pa, which is less than  $p_2$ . Hence,  $p_1 = p_2 = 1.01 \times 10^5$  Pa. The flow is unchoked (subsonic). Equation (6-115) is solved for the Mach number.

$$\frac{1.5 \times 10^5}{1.01 \times 10^5} = \left( 1 + \frac{1.4-1}{2} M_1^2 \right)^{1.4/(1.4-1)}$$

$$M_1 = 0.773$$

Substitution into Eq. (6-118) gives  $G$ .

$$G = 1.5 \times 10^5 \times \sqrt{\frac{1.4 \times 29}{8,314 \times 293}} \times \frac{0.773}{\left(1 + \frac{(1.4-1)}{2} \times 0.773^2\right)^{(1.4+1/2)(1.4-1)}} = 337 \text{ kg/m}^2 \cdot \text{s}$$

The exit temperature is found from Eq. (6-116) to be 261.6 K or  $-11.5^\circ\text{C}$ . The exit velocity is

$$V = Mc = 0.773 \times \sqrt{\frac{1.4 \times 8314 \times 261.6}{29}} = 250 \text{ m/s}$$

**Adiabatic Flow with Friction in a Duct of Constant Cross Section** Integration of the differential forms of the continuity, momentum, and total energy equations for a perfect gas, assuming a constant friction factor, leads to a tedious set of simultaneous algebraic equations. These may be found in Shapiro (*Dynamics and Thermodynamics of Compressible Fluid Flow*, vol. I, Ronald Press, New York, 1953) or Zucrow and Hoffmann (*Gas Dynamics*, vol. I, Wiley, New York, 1976). Lapple's (*Trans. AICHE*, **39**, 395–432 [1943]) widely cited graphical presentation of the solution of these equations contained a subtle error, which was corrected by Levenspiel (*AICHE J.*, **23**, 402–403 [1977]). Levenspiel's graphical solutions are presented in Fig. 6-21. These charts refer to the physical situation illustrated in Fig. 6-22, where a perfect gas discharges from stagnation conditions in a large chamber through an isentropic nozzle followed by a duct of length  $L$ . The resistance parameter is  $N = 4fL/D_H$ , where  $f = \text{Fanning friction factor}$  and  $D_H = \text{hydraulic diameter}$ .

The exit Mach number  $M_2$  may not exceed unity.  $M_2 = 1$  corresponds to choked flow; sonic conditions may exist only at the pipe exit. The mass velocity  $G^\circ$  in the charts is the choked **mass flux for an isentropic nozzle** given by Eq. (6-118). For a pipe of finite length, the mass flux is less than  $G^\circ$  under choking conditions. The curves in Fig. 6-21 become vertical at the choking point, where flow becomes independent of downstream pressure.

The equations for nozzle flow, Eqs. (6-114) through (6-118), remain valid for the nozzle section even in the presence of the discharge pipe. Equations (6-116) and (6-120), for the temperature variation, may also be used for the pipe, with  $M_2, p_2$  replacing  $M_1, p_1$  since they are valid for adiabatic flow, with or without friction.

The graphs in Fig. 6-21 are based on accurate calculations, but are difficult to interpolate precisely. While they are quite useful for rough estimates, precise calculations are best done using the equations for one-dimensional adiabatic flow with friction, which are suitable for computer programming. Let subscripts 1 and 2 denote two points along a pipe of diameter  $D$ , point 2 being downstream of point 1. From a given point in the pipe, where the Mach number is  $M$ , the additional length of pipe required to accelerate the flow to sonic velocity ( $M = 1$ ) is denoted  $L_{\text{max}}$  and may be computed from

$$\frac{4fL_{\text{max}}}{D} = \frac{1-M^2}{kM^2} + \frac{k+1}{2k} \ln \left( \frac{\frac{k+1}{2} M^2}{1 + \frac{k-1}{2} M^2} \right) \quad (6-123)$$

With  $L = \text{length of pipe between points 1 and 2}$ , the change in Mach number may be computed from

$$\frac{4fL}{D} = \left( \frac{4fL_{\text{max}}}{D} \right)_1 - \left( \frac{4fL_{\text{max}}}{D} \right)_2 \quad (6-124)$$

Equations (6-116) and (6-113), which are valid for adiabatic flow with friction, may be used to determine the temperature and speed of sound at points 1 and 2. Since the mass flux  $G = \rho v = \rho c M$  is constant, and  $\rho = PM_w/RT$ , the pressure at point 2 (or 1) can be found from  $G$  and the pressure at point 1 (or 2).

The additional frictional losses due to pipeline fittings such as elbows may be added to the velocity head loss  $N = 4fL/D_H$  using the same velocity head loss values as for incompressible flow. This works well for fittings which do not significantly reduce the channel cross-sectional area, but may cause large errors when the flow area is greatly

reduced, as, for example, by restricting orifices. Compressible flow across restricting orifices is discussed in Sec. 10 of this *Handbook*. Similarly, elbows near the exit of a pipeline may choke the flow even though the Mach number is less than unity due to the nonuniform velocity profile in the elbow. For an abrupt contraction rather than rounded nozzle inlet, an additional 0.5 velocity head should be added to  $N$ . This is a reasonable approximation for  $G$ , but note that it allocates the additional losses to the pipeline, even though they are actually incurred in the entrance. It is an error to include one velocity head exit loss in  $N$ . The kinetic energy at the exit is already accounted for in the integration of the balance equations.

**Example 8: Compressible Flow with Friction Losses** Calculate the discharge rate of air to the atmosphere from a reservoir at  $10^6 \text{ Pa}$  gauge and  $20^\circ\text{C}$  through 10 m of straight 2-in Schedule 40 steel pipe (inside diameter = 0.0525 m), and 3 standard radius, flanged  $90^\circ$  elbows. Assume 0.5 velocity heads lost for the elbows.

For commercial steel pipe, with a roughness of 0.046 mm, the friction factor for fully rough flow is about 0.0047, from Eq. (6-38) or Fig. 6-9. It remains to be verified that the Reynolds number is sufficiently large to assume fully rough flow. Assuming an abrupt entrance with 0.5 velocity heads lost,

$$N = 4 \times 0.0047 \times \frac{10}{0.0525} + 0.5 + 3 \times 0.5 = 5.6$$

The pressure ratio  $p_3/p_0$  is

$$\frac{1.01 \times 10^5}{(1 \times 10^6 + 1.01 \times 10^5)} = 0.092$$

From Fig. 6-21b at  $N = 5.6$ ,  $p_3/p_0 = 0.092$  and  $k = 1.4$  for air, the flow is seen to be choked. At the choke point with  $N = 5.6$  the critical pressure ratio  $p_2/p_0$  is about 0.25 and  $G/G^\circ$  is about 0.48. Equation (6-122) gives

$$G^\circ = 1.101 \times 10^6 \times \sqrt{\left(\frac{2}{1.4+1}\right)^{(1.4+1)(1.4-1)} \left(\frac{1.4 \times 29}{8,314 \times 293.15}\right)} = 2,600 \text{ kg/m}^2 \cdot \text{s}$$

Multiplying by  $G/G^\circ = 0.48$  yields  $G = 1,250 \text{ kg/m}^2 \cdot \text{s}$ . The discharge rate is  $w = GA = 1,250 \times \pi \times 0.0525^2/4 = 2.7 \text{ kg/s}$ .

Before accepting this solution, the Reynolds number should be checked. At the pipe exit, the temperature is given by Eq. (6-120) since the flow is choked. Thus,  $T_2 = T^* = 244.6 \text{ K}$ . The viscosity of air at this temperature is about  $1.6 \times 10^{-5} \text{ Pa} \cdot \text{s}$ . Then

$$\text{Re} = \frac{DV\rho}{\mu} = \frac{DG}{\mu} = \frac{0.0525 \times 1,250}{1.6 \times 10^{-5}} = 4.1 \times 10^6$$

At the beginning of the pipe, the temperature is greater, giving greater viscosity and a Reynolds number of  $3.6 \times 10^6$ . Over the entire pipe length the Reynolds number is very large and the fully rough flow friction factor choice was indeed valid.

Once the mass flux  $G$  has been determined, Fig. 6-21a or 6-21b can be used to determine the pressure at any point along the pipe, simply by reducing  $4fL/D_H$  and computing  $p_2$  from the figures, given  $G$ , instead of the reverse. Charts for calculation between two points in a pipe with known flow and known pressure at either upstream or downstream locations have been presented by Loeb (*Chem. Eng.*, **76**[5], 179–184 [1969]) and for known downstream conditions by Powley (*Can. J. Chem. Eng.*, **36**, 241–245 [1958]).

**Convergent/Divergent Nozzles (De Laval Nozzles)** During frictionless adiabatic one-dimensional flow with changing cross-sectional area  $A$  the following relations are obeyed:

$$\frac{dA}{A} = \frac{dp}{\rho V^2} (1 - M^2) = \frac{1 - M^2}{M^2} \frac{dp}{\rho} = -(1 - M^2) \frac{dV}{V} \quad (6-125)$$

Equation (6-125) implies that in converging channels, subsonic flows are accelerated and the pressure and density decrease. In diverging channels, subsonic flows are decelerated as the pressure and density increase. In subsonic flow, the converging channels act as nozzles and diverging channels as diffusers. In supersonic flows, the opposite is true. Diverging channels act as nozzles accelerating the flow, while converging channels act as diffusers decelerating the flow.

Figure 6-23 shows a converging/diverging nozzle. When  $p_2/p_0$  is less than the critical pressure ratio ( $p^*/p_0$ ), the flow will be subsonic in the converging portion of the nozzle, sonic at the throat, and supersonic in the diverging portion. At the throat, where the flow is critical and the velocity is sonic, the area is denoted  $A^*$ . The cross-sectional

**FIG. 6-21** Design charts for adiabatic flow of gases; (a) useful for finding the allowable pipe length for given flow rate; (b) useful for finding the discharge rate in a given piping system. (From Levenspiel, *Am. Inst. Chem. Eng. J.*, 23, 402 [1977].)

area and pressure vary with Mach number along the converging/diverging flow path according to the following equations for isentropic flow of a perfect gas:

$$\frac{A}{A^*} = \frac{1}{M} \left[ \frac{2}{k+1} \left( 1 + \frac{k-1}{2} M^2 \right) \right]^{(k+1)/2(k-1)} \quad (6-126)$$

$$\frac{p_0}{p} = \left( 1 + \frac{k-1}{2} M^2 \right)^{k/(k-1)} \quad (6-127)$$

**FIG. 6-22** Adiabatic compressible flow in a pipe with a well-rounded entrance.

FIG. 6-23 Converging/diverging nozzle.

The temperature obeys the adiabatic flow equation for a perfect gas,

$$\frac{T_0}{T} = 1 + \frac{k-1}{2} M^2 \quad (6-128)$$

Equation (6-128) does not require frictionless (isentropic) flow. The sonic mass flux through the throat is given by Eq. (6-122). With  $A$  set equal to the nozzle exit area, the exit Mach number, pressure, and temperature may be calculated. Only if the exit pressure equals the ambient discharge pressure is the ultimate expansion velocity reached in the nozzle. Expansion will be incomplete if the exit pressure exceeds the ambient discharge pressure; shocks will occur outside the nozzle. If the calculated exit pressure is less than the ambient discharge pressure, the nozzle is overexpanded and compression shocks within the expanding portion will result.

The shape of the converging section is a smooth trumpet shape similar to the simple converging nozzle. However, special shapes of the diverging section are required to produce the maximum supersonic exit velocity. Shocks result if the divergence is too rapid and excessive boundary layer friction occurs if the divergence is too shallow. See Liepmann and Roshko (*Elements of Gas Dynamics*, Wiley, New York, 1957, p. 284). If the nozzle is to be used as a thrust device, the diverging section can be conical with a total included angle of  $30^\circ$  (Sutton, *Rocket Propulsion Elements*, 2d ed., Wiley, New York, 1956). To obtain large exit Mach numbers, slot-shaped rather than axisymmetric nozzles are used.

## MULTIPHASE FLOW

Multiphase flows, even when restricted to simple pipeline geometry, are in general quite complex, and several features may be identified which make them more complicated than single-phase flow. Flow pattern description is not merely an identification of laminar or turbulent flow. The relative quantities of the phases and the topology of the interfaces must be described. Because of phase density differences, vertical flow patterns are different from horizontal flow patterns, and horizontal flows are not generally axisymmetric. Even when phase equilibrium is achieved by good mixing in two-phase flow, the changing equilibrium state as pressure drops with distance, or as heat is added or lost, may require that interphase mass transfer, and changes in the relative amounts of the phases, be considered.

Wallis (*One-dimensional Two-phase Flow*, McGraw-Hill, New York, 1969) and Govier and Aziz present mass, momentum, mechanical energy, and total energy balance equations for two-phase flows. These equations are based on one-dimensional behavior for each phase. Such equations, for the most part, are used as a framework in which to interpret experimental data. Reliable prediction of multiphase flow behavior generally requires use of data or correlations. **Two-fluid modeling**, in which the full three-dimensional microscopic (partial differential) equations of motion are written for each phase, treating each as a continuum, occupying a volume fraction which is a continuous function of position, is a rapidly developing technique made possible by improved computational methods. For some relatively simple examples not requiring numerical computation, see Pearson (*Chem. Engr. Sci.*, **49**, 727–732 [1994]). Constitutive equations for two-fluid models are not yet sufficiently robust for accurate general-purpose two-phase flow computation, but may be quite good for particular classes of flows.

**Liquids and Gases** For cocurrent flow of liquids and gases in vertical (upflow), horizontal, and inclined pipes, a very large literature of experimental and theoretical work has been published, with less work on countercurrent and cocurrent vertical downflow. Much of the effort has been devoted to predicting flow patterns, pressure drop, and volume fractions of the phases, with emphasis on fully developed flow. In practice, many two-phase flows in process plants are not fully developed.

The most reliable methods for fully developed gas/liquid flows use **mechanistic models** to predict flow pattern, and use different pressure drop and void fraction estimation procedures for each flow pattern. Such methods are too lengthy to include here, and are well suited to incorporation into computer programs; commercial codes for gas/liquid pipeline flows are available. Some key references for mechanistic methods for flow pattern transitions and flow regime-specific pressure drop and void fraction methods include Taitel and Dukler (*AIChE J.*, **22**, 47–55 [1976]), Barnea, et al. (*Int. J. Multiphase Flow*, **6**, 217–225 [1980]), Barnea (*Int. J. Multiphase Flow*, **12**, 733–744 [1986]), Taitel, Barnea, and Dukler (*AIChE J.*, **26**, 345–354 [1980]), Wallis (*One-dimensional Two-phase Flow*, McGraw-Hill, New York, 1969), and Dukler and Hubbard (*Ind. Eng. Chem. Fundam.*, **14**, 337–347 [1975]). For preliminary or approximate calculations, **flow pattern maps** and flow regime-independent empirical correlations, are simpler and faster to use. Such methods for horizontal and vertical flows are provided in the following.

In **horizontal pipe**, flow patterns for fully developed flow have been reported in numerous studies. Transitions between flow patterns are gradual, and subjective owing to the visual interpretation of individual investigators. In some cases, statistical analysis of pressure fluctuations has been used to distinguish flow patterns. Figure 6-24 (Alves, *Chem. Eng. Progr.*, **50**, 449–456 [1954]) shows seven flow patterns for horizontal gas/liquid flow. **Bubble flow** is prevalent at high ratios of liquid to gas flow rates. The gas is dispersed as bubbles which move at velocity similar to the liquid and tend to concentrate near the top of the pipe at lower liquid velocities. **Plug flow** describes a pattern in which alternate plugs of gas and liquid move along the upper part of the pipe. In **stratified flow**, the liquid flows along the bottom of the pipe and the gas flows over a smooth liquid/gas interface. Similar to stratified flow, **wavy flow** occurs at greater gas velocities and has waves moving in the flow direction. When wave crests are sufficiently high to bridge the pipe, they form frothy slugs which move at much greater than the average liquid velocity. **Slug flow** can cause severe and sometimes dangerous vibrations in equipment because of impact of the high-velocity slugs against bends or other fittings. Slugs may also flood gas/liquid separation equipment.

In **annular flow**, liquid flows as a thin film along the pipe wall and gas flows in the core. Some liquid is entrained as droplets in the gas

FIG. 6-24 Gas/liquid flow patterns in horizontal pipes. (From Alves, *Chem. Eng. Progr.*, **50**, 449–456 [1954].)

FIG. 6-25 Flow-pattern regions in cocurrent liquid/gas flow through horizontal pipes. To convert lbm/(ft<sup>2</sup> · s) to kg/(m<sup>2</sup> · s), multiply by 4.8824. (From Baker, *Oil Gas J.*, 53[12], 185–190, 192, 195 [1954].)

core. At very high gas velocities, nearly all the liquid is entrained as small droplets. This pattern is called **spray, dispersed, or mist flow**. Approximate prediction of flow pattern may be quickly done using **flow pattern maps**, an example of which is shown in Fig. 6-25 (Baker, *Oil Gas J.*, 53[12], 185–190, 192–195 [1954]). The Baker chart remains widely used; however, for critical calculations the mechanistic model methods referenced previously are generally preferred for their greater accuracy, especially for large pipe diameters and fluids with physical properties different from air/water at atmospheric pressure. In the chart,

$$\lambda = (\rho'_G \rho'_L)^{1/2} \tag{6-129}$$

$$\psi = \frac{1}{\sigma'} \left[ \frac{\mu'_L}{(\rho'_L)^2} \right]^{1/3} \tag{6-130}$$

$G_L$  and  $G_C$  are the liquid and gas mass velocities,  $\mu'_L$  is the ratio of liquid viscosity to water viscosity,  $\rho'_G$  is the ratio of gas density to air density,  $\rho'_L$  is the ratio of liquid density to water density, and  $\sigma'$  is the ratio of liquid surface tension to water surface tension. The reference properties are at 20°C (68°F) and atmospheric pressure, water density 1,000 kg/m<sup>3</sup> (62.4 lbm/ft<sup>3</sup>), air density 1.20 kg/m<sup>3</sup> (0.075 lbm/ft<sup>3</sup>), water viscosity 0.001 Pa · s (1.0 cP), and surface tension 0.073 N/m (0.0050 lbf/ft). The empirical parameters  $\lambda$  and  $\psi$  provide a crude accounting for physical properties. The Baker chart is dimensionally inconsistent since the dimensional quantity  $G_C/\lambda$  is plotted against a dimensionless one,  $G_L\lambda\psi/G_C$ , and so must be used with  $G_C$  in lbm/(ft<sup>2</sup> · s) units on the ordinate. To convert to kg/(m<sup>2</sup> · s), multiply by 4.8824.

Rapid approximate predictions of **pressure drop** for fully developed, incompressible horizontal gas/liquid flow may be made using the method of Lockhart and Martinelli (*Chem. Eng. Prog.*, 45, 39–48 [1949]). First, the pressure drops that would be expected for each of the two phases as if flowing alone in single-phase flow are calculated. The Lockhart-Martinelli parameter  $X$  is defined in terms of the ratio of these pressure drops:

$$X = \left[ \frac{(\Delta p/L)_L}{(\Delta p/L)_G} \right]^{1/2} \tag{6-131}$$

The two-phase pressure drop may then be estimated from either of the single-phase pressure drops, using

$$\left( \frac{\Delta p}{L} \right)_{TP} = Y_L \left( \frac{\Delta p}{L} \right)_L \tag{6-132}$$

or

$$\left( \frac{\Delta p}{L} \right)_{TP} = Y_C \left( \frac{\Delta p}{L} \right)_C \tag{6-133}$$

where  $Y_L$  and  $Y_C$  are read from Fig. 6-26 as functions of  $X$ . The curve labels refer to the flow regime (laminar or turbulent) found for each of

FIG. 6-26 Parameters for pressure drop in liquid/gas flow through horizontal pipes. (Based on Lockhart and Martinelli, *Chem. Eng. Prog.*, 45, 39 [1949].)

the phases flowing alone. The common turbulent-turbulent case is approximated well by

$$Y_L = 1 + \frac{20}{X} + \frac{1}{X^2} \tag{6-134}$$

Lockhart and Martinelli (ibid.) correlated pressure drop data from pipes 25 mm (1 in) in diameter or less within about ±50 percent. In general, the predictions are high for stratified, wavy, and slug flows and low for annular flow. The correlation can be applied to pipe diameters up to about 0.1 m (4 in) with about the same accuracy.

The **volume fraction**, sometimes called **holdup**, of each phase in two-phase flow is generally not equal to its volumetric flow rate fraction, because of velocity differences, or **slip**, between the phases. For each phase, denoted by subscript  $i$ , the relations among superficial velocity  $V_b$ , in situ velocity  $v_b$ , volume fraction  $R_b$ , total volumetric flow rate  $Q_b$ , and pipe area  $A$  are

$$Q_i = V_i A = v_i R_i A \tag{6-135}$$

$$v_i = \frac{V_i}{R_i} \tag{6-136}$$

The **slip velocity** between gas and liquid is  $v_s = v_G - v_L$ . For two-phase gas/liquid flow,  $R_L + R_G = 1$ . A very common mistake in practice is to assume that in situ phase volume fractions are equal to input volume fractions.

For fully developed incompressible horizontal gas/liquid flow, a quick estimate for  $R_L$  may be obtained from Fig. 6-27, as a function of the Lockhart-Martinelli parameter  $X$  defined by Eq. (6-131). Indications are that liquid volume fractions may be overpredicted for liquids more viscous than water (Alves, *Chem. Eng. Prog.*, 50, 449–456 [1954]), and underpredicted for pipes larger than 25 mm diameter (Baker, *Oil Gas J.*, 53[12], 185–190, 192–195 [1954]).

A method for predicting pressure drop and volume fraction for **non-Newtonian fluids** in annular flow has been proposed by Eisenberg and Weinberger (*AIChE J.*, 25, 240–245 [1979]). Das, Biswas, and Matra (*Can. J. Chem. Eng.*, 70, 431–437 [1993]) studied holdup in both horizontal and vertical gas/liquid flow with non-Newtonian liquids. Farooqi and Richardson (*Trans. Inst. Chem. Engrs.*, 60, 292–305, 323–333 [1982]) developed correlations for holdup and pressure drop for gas/non-Newtonian liquid horizontal flow. They used a modified Lockhart-Martinelli parameter for non-Newtonian

FIG. 6-27 Liquid volume fraction in liquid/gas flow through horizontal pipes. (From Lockhart and Martinelli, *Eng. Prog.*, **45**, 39 [1949].)

liquid holdup. They found that two-phase pressure drop may actually be less than the single-phase liquid pressure drop with shear thinning liquids in laminar flow.

Pressure drop data for a 1-in feed tee with the liquid entering the run and gas entering the branch are given by Alves (*Chem. Eng. Progr.*, **50**, 449–456 [1954]). Pressure drop and division of two-phase annular flow in a tee are discussed by Fouada and Rhodes (*Trans. Inst. Chem. Eng. [London]*, **52**, 354–360 [1974]). Flow through tees can result in unexpected flow splitting. Further reading on gas/liquid flow through tees may be found in Mudde, Groen, and van den Akker (*Int. J. Multiphase Flow*, **19**, 563–573 [1993]); Issa and Oliveira (*Computers and Fluids*, **23**, 347–372 [1993]) and Azzopardi and Smith (*Int. J. Multiphase Flow*, **18**, 861–875 [1992]).

Results by Chenoweth and Martin (*Pet. Refiner*, **34**[10], 151–155 [1955]) indicate that single-phase data for fittings and valves can be used in their correlation for two-phase pressure drop. Smith, Murdock, and Applebaum (*J. Eng. Power*, **99**, 343–347 [1977]) evaluated existing correlations for two-phase flow of steam/water and other gas/liquid mixtures through sharp-edged orifices meeting ASTM standards for flow measurement. The correlation of Murdock (*J. Basic Eng.*, **84**, 419–433 [1962]) may be used for these orifices. See also Collins and Gaceta (*J. Basic Eng.*, **93**, 11–21 [1971]), for measurements with steam and water beyond the limits of this correlation.

For pressure drop and holdup in inclined pipe with upward or downward flow, see Beggs and Brill (*J. Pet. Technol.*, **25**, 607–617 [1973]); the mechanistic model methods referenced above may also be applied to inclined pipes. Up to 10° from horizontal, upward pipe inclination has little effect on holdup (Gregory, *Can. J. Chem. Eng.*, **53**, 384–388 [1975]).

For fully developed incompressible cocurrent upflow of gases and liquids in vertical pipes, a variety of flow pattern terminologies and descriptions have appeared in the literature; some of these have been summarized and compared by Govier, Radford, and Dunn (*Can. J. Chem. Eng.*, **35**, 58–70 [1957]). One reasonable classification of patterns is illustrated in Fig. 6-28.

In bubble flow, gas is dispersed as bubbles throughout the liquid, but with some tendency to concentrate toward the center of the pipe. In slug flow, the gas forms large Taylor bubbles of diameter nearly equal to the pipe diameter. A thin film of liquid surrounds the Taylor bubble. Between the Taylor bubbles are liquid slugs containing some bubbles. Froth or churn flow is characterized by strong intermittency and intense mixing, with neither phase easily described as continuous or dispersed. There remains disagreement in the literature as to whether churn flow is a real fully developed flow pattern or is an indication of large entry length for developing slug flow (Zao and Dukler, *Int. J. Multiphase Flow*, **19**, 377–383 [1993]; Hewitt and Jayanti, *Int. J. Multiphase Flow*, **19**, 527–529 [1993]).

Ripple flow has an upward-moving wavy layer of liquid on the pipe wall; it may be thought of as a transition region to annular, annular mist, or film flow, in which gas flows in the core of the pipe while an annulus of liquid flows up the pipe wall. Some of the liquid is

FIG. 6-28 Flow patterns in cocurrent upward vertical gas/liquid flow. (From Taitel, Barnea, and Dukler, *AIChE J.*, **26**, 345–354 [1980]. Reproduced by permission of the American Institute of Chemical Engineers © 1980 AIChE. All rights reserved.)

entrained as droplets in the gas core. Mist flow occurs when all the liquid is carried as fine drops in the gas phase; this pattern occurs at high gas velocities, typically 20 to 30 m/s (66 to 98 ft/s).

The correlation by Govier, et al. (*Can. J. Chem. Eng.*, **35**, 58–70 [1957]), Fig. 6-29, may be used for quick estimate of flow pattern.

Slip, or relative velocity between phases, occurs for vertical flow as well as for horizontal. No completely satisfactory, flow regime-independent correlation for volume fraction or holdup exists for vertical flow. Two frequently used flow regime-independent methods are those by Hughmark and Pressburg (*AIChE J.*, **7**, 677 [1961]) and Hughmark (*Chem. Eng. Progr.*, **58**[4], 62 [April 1962]). Pressure drop in upflow may be calculated by the procedure described in Hughmark (*Ind. Eng. Chem. Fundam.*, **2**, 315–321 [1963]). The mechanistic, flow regime-based methods are advisable for critical applications.

For upflow in helically coiled tubes, the flow pattern, pressure drop, and holdup can be predicted by the correlations of Banerjee, Rhodes, and Scott (*Can. J. Chem. Eng.*, **47**, 445–453 [1969]) and

FIG. 6-29 Flow-pattern regions in cocurrent liquid/gas flow in upflow through vertical pipes. To convert ft/s to m/s, multiply by 0.3048. (From Govier, Radford, and Dunn, *Can. J. Chem. Eng.*, **35**, 58–70 [1957].)

FIG. 6-30 Critical head for drain and overflow pipes. (From Kalinske, Univ. Iowa Stud. Eng., Bull. 26 [1939-1940].)

Akagawa, Sakaguchi, and Ueda (*Bull JSME*, 14, 564-571 [1971]). Correlations for flow patterns in **downflow** in vertical pipe are given by Oshinowo and Charles (*Can. J. Chem. Eng.*, 52, 25-35 [1974]) and Barnea, Shoham, and Taitel (*Chem. Eng. Sci.*, 37, 741-744 [1982]). Use of **drift flux theory** for void fraction modeling in downflow is presented by Clark and Flemmer (*Chem. Eng. Sci.*, 39, 170-173 [1984]). **Downward inclined** two-phase flow data and modeling are given by Barnea, Shoham, and Taitel (*Chem. Eng. Sci.*, 37, 735-740 [1982]). Data for **downflow in helically coiled tubes** are presented by Casper (*Chem. Ing. Tech.*, 42, 349-354 [1970]).

The entrance to a **drain** is flush with a horizontal surface, while the entrance to an **overflow** pipe is above the horizontal surface. When such pipes do not run full, considerable amounts of gas can be drawn down by the liquid. The amount of gas entrained is a function of pipe diameter, pipe length, and liquid flow rate, as well as the drainpipe outlet boundary condition. Extensive data on air entrainment and liquid head above the entrance as a function of water flow rate for pipe diameters from 43.9 to 148.3 mm (1.7 to 5.8 in) and lengths from about 1.22 to 5.18 m (4.0 to 17.0 ft) are reported by Kalinske (*Univ. Iowa Stud. Eng., Bull.* 26, pp. 26-40 [1939-1940]). For heads greater than the critical, the pipes will run full with no entrainment. The critical head  $h$  for flow of water in drains and overflow pipes is given in Fig. 6-30. Kalinske's results show little effect of the height of protrusion of overflow pipes when the protrusion height is greater than about one pipe diameter. For conservative design, McDuffie (*AIChE J.*, 23, 37-40 [1977]) recommends the following relation for minimum liquid height to prevent entrainment.

$$Fr \leq 1.6 \left( \frac{h}{D} \right)^2 \tag{6-137}$$

where the Froude number is defined by

$$Fr \equiv \frac{V_L}{\sqrt{g(\rho_L - \rho_C)D/\rho_L}} \tag{6-138}$$

where  $g$  = acceleration due to gravity  
 $V_L$  = liquid velocity in the drain pipe  
 $\rho_L$  = liquid density  
 $\rho_C$  = gas density  
 $D$  = pipe inside diameter  
 $h$  = liquid height

For additional information, see Simpson (*Chem. Eng.*, 75[6], 192-214 [1968]). A critical Froude number of 0.31 to ensure vented flow is widely cited. Recent results (Thorpe, *3d Int. Conf. Multi-phase Flow*, The Hague, Netherlands, 18-20 May 1987, paper K2, and *4th Int. Conf. Multi-phase Flow*, Nice, France, 19-21 June 1989, paper K4) show hysteresis, with different critical Froude numbers for flooding and unflowing of drain pipes, and the influence of end effects. Wallis, Crowley, and Hagi (*Trans. ASME J. Fluids Eng.*, 405-413 [June 1977]) examine the conditions for horizontal discharge pipes to run full.

**Flashing flow** and **condensing flow** are two examples of multi-phase flow with **phase change**. Flashing flow occurs when pressure drops below the bubble point pressure of a flowing liquid. A frequently

used one-dimensional model for flashing flow through nozzles and pipes is the **homogeneous equilibrium model** which assumes that both phases move at the same in situ velocity, and maintain vapor/liquid equilibrium. It may be shown that a **critical flow** condition, analogous to sonic or critical flow during compressible gas flow, is given by the following expression for the mass flux  $G$  in terms of the derivative of pressure  $p$  with respect to mixture density  $\rho_m$  at constant entropy:

$$G_{crit} = \rho_m \sqrt{\left( \frac{\partial p}{\partial \rho_m} \right)_s} \tag{6-139}$$

The corresponding acoustic velocity  $\sqrt{(\partial p / \partial \rho_m)_s}$  is normally much less than the acoustic velocity for gas flow. The mixture density is given in terms of the individual phase densities and the **quality** (mass flow fraction vapor)  $x$  by

$$\frac{1}{\rho_m} = \frac{x}{\rho_C} + \frac{1-x}{\rho_L} \tag{6-140}$$

Choked and unchoked flow situations arise in pipes and nozzles in the same fashion for homogeneous equilibrium flashing flow as for gas flow. For nozzle flow from stagnation pressure  $p_0$  to exit pressure  $p_1$ , the mass flux is given by

$$G^2 = -2\rho_{m1}^2 \int_{p_0}^{p_1} \frac{dp}{\rho_m} \tag{6-141}$$

The integration is carried out over an isentropic flash path: flashes at constant entropy must be carried out to evaluate  $\rho_m$  as a function of  $p$ . Experience shows that isenthalpic flashes provide good approximations unless the liquid mass fraction is very small. Choking occurs when  $G$  obtained by Eq. (6-141) goes through a maximum at a value of  $p_1$  greater than the external discharge pressure. Equation (6-139) will also be satisfied at that point. In such a case the pressure at the nozzle exit equals the choking pressure and flashing shocks occur outside the nozzle exit.

For homogeneous flow in a pipe of diameter  $D$ , the differential form of the Bernoulli equation (6-15) rearranges to

$$\frac{dp}{\rho_m} + g dz + \frac{G^2}{\rho_m} d \frac{1}{\rho_m} + 2f \frac{dx'}{D} \frac{G^2}{\rho_m^2} = 0 \tag{6-142}$$

where  $x'$  is distance along the pipe. Integration over a length  $L$  of pipe assuming constant friction factor  $f$  yields

$$G^2 = \frac{-\int_{p_1}^{p_2} \rho_m dp - g \int_{z_1}^{z_2} \rho_m^2 dz}{\ln(\rho_{m1}/\rho_{m2}) + 2fL/D} \tag{6-143}$$

Frictional pipe flow is not isentropic. Strictly speaking, the flashes must be carried out at constant  $h + V^2/2 + gz$ , where  $h$  is the enthalpy per unit mass of the two-phase flashing mixture. The flash calculations are fully coupled with the integration of the Bernoulli equation; the velocity  $V$  must be known at every pressure  $p$  to evaluate  $\rho_m$ . Computational routines, employing the thermodynamic and material balance features of flowsheet simulators, are the most practical way to carry out such flashing flow calculations, particularly when multicomponent systems are involved. Significant simplification arises when the mass fraction liquid is large, for then the effect of the  $V^2/2$  term on the flash splits may be neglected. If elevation effects are also negligible, the flash computations are decoupled from the Bernoulli equation integration. For many horizontal flashing flow calculations, this is satisfactory and the flash computations may be carried out first, to find  $\rho_m$  as a function of  $p$  from  $p_1$  to  $p_2$ , which may then be substituted into Eq. (6-143).

With flashes carried out along the appropriate thermodynamic paths, the formalism of Eqs. (6-139) through (6-143) applies to all homogeneous equilibrium compressible flows, including, for example, flashing flow, ideal gas flow, and nonideal gas flow. Equation (6-118), for example, is a special case of Eq. (6-141) where the quality  $x = 1$  and the vapor phase is a perfect gas.

Various **nonequilibrium** and **slip** flow models have been proposed as improvements on the homogeneous equilibrium flow model. See, for example, Henry and Fauske (*Trans. ASME J. Heat Transfer*, 179-187 [May 1971]). Nonequilibrium and slip effects both increase

computed mass flux for fixed pressure drop, compared to homogeneous equilibrium flow. For flow paths greater than about 100 mm, homogeneous equilibrium behavior appears to be the best assumption (Fischer, et al., *Emergency Relief System Design Using DIERS Technology*, AIChE, New York [1992]). For shorter flow paths, the best estimate may sometimes be given by linearly interpolating (as a function of length) between **frozen flow** (constant quality, no flashing) at 0 length and equilibrium flow at 100 mm.

In a series of papers by Leung and coworkers (*AIChE J.*, **32**, 1743–1746 [1986]; **33**, 524–527 [1987]; **34**, 688–691 [1988]; *J. Loss Prevention Proc. Ind.*, **2**[2], 78–86 [April 1989]; **3**[1], 27–32 [January 1990]; *Trans. ASME J. Heat Transfer*, **112**, 524–528, 528–530 [1990]; **113**, 269–272 [1991]) approximate techniques have been developed for homogeneous equilibrium calculations based on pseudo-equation of state methods for flashing mixtures.

Relatively less work has been done on **condensing flows**. Slip effects are more important for condensing than for flashing flows. Soliman, Schuster, and Berenson (*J. Heat Transfer*, **90**, 267–276 [1968]) give a model for condensing vapor in **horizontal pipe**. They assume the condensate flows as an annular ring. The Lockhart-Martinelli correlation is used for the frictional pressure drop. To this pressure drop is added an acceleration term based on homogeneous flow, equivalent to the  $C^2 d(1/\rho_m)$  term in Eq. (6-142). Pressure drop is computed by integration of the incremental pressure changes along the length of pipe.

For **condensing vapor in vertical downflow**, in which the liquid flows as a thin annular film, the frictional contribution to the pressure drop may be estimated based on the gas flow alone, using the friction factor plotted in Fig. 6-31, where  $Re_c$  is the Reynolds number for the gas flowing alone (Bergelin et al., *Proc. Heat Transfer Fluid Mech. Inst.*, ASME, June 22–24, 1949, pp. 19–28).

$$-\frac{dp}{dz} = \frac{2f_c \rho_c V_c^2}{D} \quad (6-144)$$

To this should be added the  $C_c^2 d(1/\rho_c)/dx$  term to account for velocity change effects.

**Gases and Solids** The flow of gases and solids in **horizontal pipe** is usually classified as either **dilute phase** or **dense phase** flow. Unfortunately, there is no clear delineation between the two types of flow, and the **dense phase** description may take on more than one meaning, creating some confusion (Knowlton et al., *Chem. Eng. Progr.*, **90**[4], 44–54 [April 1994]). For dilute phase flow, achieved at low solids-to-gas weight ratios (loadings), and high gas velocities, the solids may be fully suspended and fairly uniformly dispersed over the pipe cross section (homogeneous flow), particularly for low-density or small particle size solids. At lower gas velocities, the solids may

**FIG. 6-31** Friction factors for condensing liquid/gas flow downward in vertical pipe. In this correlation  $\Gamma/\rho L$  is in  $\text{ft}^2/\text{h}$ . To convert  $\text{ft}^2/\text{h}$  to  $\text{m}^2/\text{s}$ , multiply by 0.00155. (From Bergelin et al., *Proc. Heat Transfer Fluid Mech. Inst.*, ASME, 1949, p. 19.)

bounce along the bottom of the pipe. With higher loadings and lower gas velocities, the particles may settle to the bottom of the pipe, forming dunes, with the particles moving from dune to dune. In dense phase conveying, solids tend to concentrate in the lower portion of the pipe at high gas velocity. As gas velocity decreases, the solids may first form dense moving strands, followed by slugs. Discrete plugs of solids may be created intentionally by timed injection of solids, or the plugs may form spontaneously. Eventually the pipe may become blocked. For more information on flow patterns, see Coulson and Richardson (*Chemical Engineering*, vol. 2, 2d ed., Pergamon, New York, 1968, p. 583); Korn (*Chem. Eng.*, **57**[3], 108–111 [1950]); Patterson (*J. Eng. Power*, **81**, 43–54 [1959]); Wen and Simons (*AIChE J.*, **5**, 263–267 [1959]); and Knowlton et al. (*Chem. Eng. Progr.*, **90**[4], 44–54 [April 1994]).

For the **minimum velocity** required to prevent formation of dunes or settled beds in **horizontal flow**, some data are given by Zenz (*Ind. Eng. Chem. Fundam.*, **3**, 65–75 [1964]), who presented a correlation for the minimum velocity required to keep particles from depositing on the bottom of the pipe. This rather tedious estimation procedure may also be found in Govier and Aziz, who provide additional references and discussion on transition velocities. In practice, the actual conveying velocities used in systems with loadings less than 10 are generally over 15 m/s (49 ft/s) while for high loadings (>20) they are generally less than 7.5 m/s (24.6 ft/s) and are roughly twice the actual solids velocity (Wen and Simons, *AIChE J.*, **5**, 263–267 [1959]).

**Total pressure drop for horizontal gas/solid flow** includes acceleration effects at the entrance to the pipe and frictional effects beyond the entrance region. A great number of correlations for pressure gradient are available, none of which is applicable to all flow regimes. Govier and Aziz review many of these and provide recommendations on when to use them.

For **upflow** of gases and solids in **vertical pipes**, the **minimum conveying velocity** for low loadings may be estimated as twice the terminal settling velocity of the largest particles. Equations for terminal settling velocity are found in the “Particle Dynamics” subsection, following. **Choking** occurs as the velocity is dropped below the minimum conveying velocity and the solids are no longer transported, collapsing into solid plugs (Knowlton, et al., *Chem. Eng. Progr.*, **90**[4], 44–54 [April 1994]). See Smith (*Chem. Eng. Sci.*, **33**, 745–749 [1978]) for an equation to predict the onset of choking.

**Total pressure drop** for vertical upflow of gases and solids includes acceleration and frictional effects also found in horizontal flow, plus potential energy or hydrostatic effects. Govier and Aziz review many of the pressure drop calculation methods and provide recommendations for their use. See also Yang (*AIChE J.*, **24**, 548–552 [1978]).

**Drag reduction** has been reported for low loadings of small diameter particles (<60  $\mu\text{m}$  diameter), ascribed to damping of turbulence near the wall (Rossettia and Pfeffer, *AIChE J.*, **18**, 31–39 [1972]).

For **dense phase transport in vertical pipes** of small diameter, see Sandy, Daubert, and Jones (*Chem. Eng. Progr.*, **66**, *Symp. Ser.*, 105, 133–142 [1970]).

The **flow of bulk solids through restrictions and bins** is discussed in symposium articles (*J. Eng. Ind.*, **91**[2] [1969]) and by Stepanoff (*Gravity Flow of Bulk Solids and Transportation of Solids in Suspension*, Wiley, New York, 1969). Some problems encountered in discharge from bins include (Knowlton et al., *Chem. Eng. Progr.*, **90**[4], 44–54 [April 1994]) flow stoppage due to **ratholing** or **arching**, **segregation** of fine and coarse particles, **flooding** upon collapse of ratholes, and poor **residence time distribution** when **funnel flow** occurs.

**Solid and Liquids** Slurry flow may be divided roughly into two categories based on settling behavior (see Etchells in Shamlou, *Processing of Solid-Liquid Suspensions*, Chap. 12, Butterworth-Heinemann, Oxford, 1993). **Nonsettling** slurries are made up of very fine, highly concentrated, or neutrally buoyant particles. These slurries are normally treated as pseudohomogeneous fluids. They may be quite viscous and are frequently non-Newtonian. Slurries of particles that tend to settle out rapidly are called **settling slurries** or **fast-settling slurries**. While in some cases positively buoyant solids are encountered, the present discussion will focus on solids which are more dense than the liquid.

For **horizontal flow of fast-settling slurries**, the following rough description may be made (Govier and Aziz). Ultrafine particles, 10  $\mu\text{m}$

FIG. 6-32 Flow pattern regimes and pressure gradients in horizontal slurry flow. (From Govier and Aziz, *The Flow of Complex Mixtures in Pipes*, Van Nostrand Reinhold, New York, 1972.)

or smaller, are generally fully suspended and the particle distributions are not influenced by gravity. Fine particles 10 to 100 μm (3.3 × 10<sup>-5</sup> to 33 × 10<sup>-5</sup> ft) are usually fully suspended, but gravity causes concentration gradients. Medium-size particles, 100 to 1000 μm, may be fully suspended at high velocity, but often form a moving deposit on the bottom of the pipe. Coarse particles, 1,000 to 10,000 μm (0.0033 to 0.033 ft), are seldom fully suspended and are usually conveyed as a moving deposit. Ultracoarse particles larger than 10,000 μm (0.033 ft) are not suspended at normal velocities unless they are unusually light.

Figure 6-32, taken from Govier and Aziz, schematically indicates four flow pattern regions superimposed on a plot of pressure gradient vs. mixture velocity  $V_M = V_L + V_S = (Q_L + Q_S)/A$  where  $V_L$  and  $V_S$  are the superficial liquid and solid velocities,  $Q_L$  and  $Q_S$  are liquid and solid volumetric flow rates, and  $A$  is the pipe cross-sectional area.  $V_{M4}$  is the transition velocity above which a bed exists in the bottom of the pipe, part of which is stationary and part of which moves by saltation, with the upper particles tumbling and bouncing over one another, often with formation of dunes. With a broad particle-size distribution, the finer particles may be fully suspended. Near  $V_{M3}$ , the pressure gradient rapidly increases as  $V_M$  decreases. Above  $V_{M3}$ , the entire bed moves. Above  $V_{M2}$ , the solids are fully suspended; that is, there is no deposit, moving or stationary, on the bottom of the pipe. However, the concentration distribution of solids is asymmetric. This flow pattern is the most frequently used for fast-settling slurry transport. Typical mixture velocities are in the range of 1 to 3 m/s (3.3 to 9.8 ft/s). The minimum in the pressure gradient is found to be near  $V_{M2}$ . Above  $V_{M1}$ , the particles are symmetrically distributed, and the pressure gradient curve is nearly parallel to that for the liquid by itself.

The most important transition velocity, often regarded as the minimum transport or conveying velocity for settling slurries, is  $V_{M2}$ . The Durand equation (Durand, Minnesota Int. Hydraulics Conf., Proc., 89, Int. Assoc. for Hydraulic Research [1953]; Durand and Condolios, Proc. Colloq. On the Hyd. Transport of Solids in Pipes, Nat. Coal Board [UK], Paper IV, 39-35 [1952]) gives the minimum transport velocity as

$$V_{M2} = F_L [2gD(s - 1)]^{0.5} \tag{6-145}$$

- where  $g$  = acceleration of gravity
- $D$  = pipe diameter
- $s = \rho_s/\rho_L$  = ratio of solid to liquid density
- $F_L$  = a factor influenced by particle size and concentration

Probably  $F_L$  is a function of particle Reynolds number and concentration, but Fig. 6-33 gives Durand's empirical correlation for  $F_L$  as a function of particle diameter and the input, feed volume fraction

FIG. 6-33 Durand factor for minimum suspension velocity. (From Govier and Aziz, *The Flow of Complex Mixtures in Pipes*, Van Nostrand Reinhold, New York, 1972.)

solids,  $C_S = Q_S/(Q_S + Q_L)$ . The form of Eq. (6-145) may be derived from turbulence theory, as shown by Davies (*Chem. Eng. Sci.*, **42**, 1667-1670 [1987]).

No single correlation for **pressure drop** in horizontal solid/liquid flow has been found satisfactory for all particle sizes, densities, concentrations, and pipe sizes. However, with reference to Fig. 6-32, the following simplifications may be considered. The minimum pressure gradient occurs near  $V_{M2}$  and for conservative purposes it is generally desirable to exceed  $V_{M2}$ . When  $V_{M2}$  is exceeded, a rough guide for pressure drop is 25 percent greater than that calculated assuming that the slurry behaves as a pseudohomogeneous fluid with the density of the mixture and the viscosity of the liquid. Above the transition velocity to symmetric suspension,  $V_{M1}$ , the pressure drop closely approaches the pseudohomogeneous pressure drop. The following correlation by Spells (*Trans. Inst. Chem. Eng. [London]*, **33**, 79-84 [1955]) may be used for  $V_{M1}$ .

$$V_{M1}^2 = 0.075 \left( \frac{DV_{M1}\rho_M}{\mu} \right)^{0.775} gD_S(s - 1) \tag{6-146}$$

- where  $D$  = pipe diameter
- $D_S$  = particle diameter (such that 85 percent by weight of particles are smaller than  $D_S$ )
- $\rho_M$  = the slurry mixture density
- $\mu$  = liquid viscosity
- $s = \rho_s/\rho_L$  = ratio of solid to liquid density

Between  $V_{M2}$  and  $V_{M1}$  the concentration of solids gradually becomes more uniform in the vertical direction. This transition has been modeled by several authors as a concentration gradient where turbulent diffusion balances gravitational settling. See, for example, Karabelas (*AIChE J.*, **23**, 426-434 [1977]).

Published correlations for pressure drop are frequently very complicated and tedious to use, may not offer significant accuracy advantages over the simple guide given here, and many of them are applicable only for velocities above  $V_{M2}$ . One which does include the effect of sliding beds is due to Gaessler (Doctoral Dissertation, Technische Hochschule, Karlsruhe, Germany [1967]; reproduced by Govier and Aziz, pp. 668-669). Turian and Yuan (*AIChE J.*, **23**, 232-243 [1977]; see also Turian and Oroskar, *AIChE J.*, **24**, 1144 [1978]) segregated a large body of data into four flow regime groups

and developed empirical correlations for predicting pressure drop in each flow regime.

Pressure drop data for the flow of **paper stock** in pipes are given in the data section of *Standards of the Hydraulic Institute* (Hydraulic Institute, 1965). The flow behavior of fiber suspensions is discussed by Bobkovicz and Gauvin (*Chem. Eng. Sci.*, **22**, 229–241 [1967]), Bugliarello and Daily (*TAPPI*, **44**, 881–893 [1961]), and Daily and Bugliarello (*TAPPI*, **44**, 497–512 [1961]).

In **vertical flow** of fast-settling slurries, the in situ concentration of solids with density greater than the liquid will exceed the feed concentration  $C = Q_s/(Q_s + Q_l)$  for upflow and will be smaller than  $C$  for downflow. This results from slip between the phases. The **slip velocity**, the difference between the in situ average velocities of the two phases, is roughly equal to the terminal settling velocity of the solids in the liquid. Specification of the slip velocity for a pipe of a given diameter, along with the phase flow rates, allows calculation of in situ volume fractions, average velocities, and holdup ratios by simple material balances. Slip velocity may be affected by particle concentration and by turbulence conditions in the liquid. **Drift-flux theory**, a framework incorporating certain functional forms for empirical expressions for slip velocity, is described by Wallis (*One-Dimensional Two-Phase Flow*, McGraw-Hill, New York, 1969). **Minimum transport velocity** for upflow for design purposes is usually taken as twice the particle settling velocity. **Pressure drop** in vertical pipe flow includes the effects of kinetic and potential energy (elevation) changes and friction. Rose and Duckworth (*The Engineer*, **227**[5,903], 392 [1969]; **227**[5,904], 430 [1969]; **227**[5,905], 478 [1969]; see also Govier and Aziz, pp. 487–493) have developed a calculation procedure including all these effects, which may be applied not only to vertical solid/liquid flow, but also to gas/solid flow and to horizontal flow.

For fast-settling slurries, ensuring conveyance is usually the key design issue while pressure drop is somewhat less important. For **nonsettling slurries** conveyance is not an issue, because the particles do not separate from the liquid. Here, viscous and rheological behavior, which control pressure drop, take on critical importance.

Fine particles, often at high concentration, form nonsettling slurries for which useful design equations can be developed by treating them as homogeneous fluids. These fluids are usually very viscous and often non-Newtonian. Shear-thinning and Bingham plastic behavior are common; dilatancy is sometimes observed. Rheology of such fluids must in general be empirically determined, although theoretical results are available for some very limited circumstances. Further discussion of both fast-settling and nonsettling slurries may be found in Shook (in Shamlou, *Processing of Solid-Liquid Suspensions*, Chap. 11, Butterworth-Heinemann, Oxford, 1993).

## FLUID DISTRIBUTION

Uniform fluid distribution is essential for efficient operation of chemical-processing equipment such as contactors, reactors, mixers, burners, heat exchangers, extrusion dies, and textile-spinning chimneys. To obtain optimum distribution, proper consideration must be given to flow behavior in the distributor, flow conditions upstream and downstream of the distributor, and the distribution requirements of the equipment. Even though the principles of fluid distribution have been well developed for more than three decades, they are frequently overlooked by equipment designers, and a significant fraction of process equipment needlessly suffers from maldistribution. In this subsection, guides for the design of various types of fluid distributors, taking into account only the flow behavior within the distributor, are given.

**Perforated-Pipe Distributors** The simple perforated pipe or sparger (Fig. 6-34) is a common type of distributor. As shown, the flow

FIG. 6-34 Perforated-pipe distributor.

distribution is uniform; this is the case in which pressure recovery due to kinetic energy or momentum changes, frictional pressure drop along the length of the pipe, and pressure drop across the outlet holes have been properly considered. In typical turbulent flow applications, inertial effects associated with velocity changes may dominate frictional losses in determining the pressure distribution along the pipe, unless the length between orifices is large. Application of the momentum or mechanical energy equations in such a case shows that the pressure inside the pipe increases with distance from the entrance of the pipe. If the outlet holes are uniform in size and spacing, the discharge flow will be biased toward the closed end. Disturbances upstream of the distributor, such as pipe bends, may increase or decrease the flow to the holes at the beginning of the distributor. When frictional pressure drop dominates the inertial pressure recovery, the distribution is biased toward the feed end of the distributor.

For turbulent flow, with roughly uniform distribution, assuming a constant friction factor, the combined effect of friction and inertial (momentum) pressure recovery is given by

$$\Delta p = \left( \frac{4fL}{3D} - 2K \right) \frac{\rho V_i^2}{2} \quad (\text{discharge manifolds}) \quad (6-147)$$

where  $\Delta p$  = net pressure drop over the length of the distributor

$L$  = pipe length

$D$  = pipe diameter

$f$  = Fanning friction factor

$V_i$  = distributor inlet velocity

The factor  $K$  would be 1 in the case of full momentum recovery, or 0.5 in the case of negligible viscous losses in the portion of flow which remains in the pipe after the flow divides at a takeoff point (Denn, pp. 126–127). Experimental data (Van der Hegge Zijnen, *Appl. Sci. Res.*, **A3**, 144–162 [1951–1953]; and Bailey, *J. Mech. Eng. Sci.*, **17**, 338–347 [1975]), while scattered, show that  $K$  is probably close to 0.5 for discharge manifolds. For inertially dominated flows,  $\Delta p$  will be negative. For **return manifolds** the recovery factor  $K$  is close to 1.0, and the pressure drop between the first hole and the exit is given by

$$\Delta p = \left( \frac{4fL}{3D} + 2K \right) \frac{\rho V_e^2}{2} \quad (\text{return manifolds}) \quad (6-148)$$

where  $V_e$  is the pipe exit velocity.

One means to obtain a desired uniform distribution is to make the average pressure drop across the holes  $\Delta p_o$  large compared to the pressure variation over the length of pipe  $\Delta p$ . Then, the relative variation in pressure drop across the various holes will be small, and so will be the variation in flow. When the area of an individual hole is small compared to the cross-sectional area of the pipe, hole pressure drop may be expressed in terms of the discharge coefficient  $C_o$  and the velocity across the hole  $V_o$  as

$$\Delta p_o = \frac{1}{C_o^2} \frac{\rho V_o^2}{2} \quad (6-149)$$

Provided  $C_o$  is the same for all the holes, the *percent maldistribution*, defined as the percentage variation in flow between the first and last holes, may be estimated reasonably well for small maldistribution by (Senecal, *Ind. Eng. Chem.*, **49**, 993–997 [1957])

$$\text{Percent maldistribution} = 100 \left( 1 - \sqrt{\frac{\Delta p_o - |\Delta p|}{\Delta p_o}} \right) \quad (6-150)$$

This equation shows that for 5 percent maldistribution, the pressure drop across the holes should be about 10 times the pressure drop over the length of the pipe. For discharge manifolds with  $K = 0.5$  in Eq. (6-147), and with  $4fL/3D \ll 1$ , the pressure drop across the holes should be 10 times the inlet velocity head,  $\rho V_i^2/2$  for 5 percent maldistribution. This leads to a simple design equation.

Discharge manifolds,  $4fL/3D \ll 1$ , 5% maldistribution:

$$\frac{V_o}{V_i} = \frac{A_p}{A_o} = \sqrt{10C_o} \quad (6-151)$$

Here  $A_p$  = pipe cross-sectional area and  $A_o$  is the total hole area of the distributor. Use of large hole velocity to pipe velocity ratios promotes perpendicular discharge streams. In practice, there are many cases where the  $4fL/3D$  term will be less than unity but not close to zero. In such cases, Eq. (6-151) will be conservative, while Eqs. (6-147), (6-149), and (6-150) will give more accurate design calculations. In cases where  $4fL/(3D) > 2$ , friction effects are large enough to render Eq. (6-151) nonconservative. When significant variations in  $f$  along the length of the distributor occur, calculations should be made by dividing the distributor into small enough sections that constant  $f$  may be assumed over each section.

For return manifolds with  $K = 1.0$  and  $4fL/(3D) \ll 1$ , 5 percent maldistribution is achieved when hole pressure drop is 20 times the pipe exit velocity head.

Return manifolds,  $4fL/3D \ll 1$ , 5% maldistribution:

$$\frac{V_o}{V_e} = \frac{A_p}{A_o} = \sqrt{20C_o} \tag{6-152}$$

When  $4fL/3D$  is not negligible, Eq. (6-152) is not conservative and Eqs. (6-148), (6-149), and (6-150) should be used.

One common misconception is that good distribution is always provided by high pressure drop, so that increasing flow rate improves distribution by increasing pressure drop. Conversely, it is mistakenly believed that turndown of flow through a perforated pipe designed using Eqs. (6-151) and (6-152) will cause maldistribution. However, when the distribution is nearly uniform, decreasing the flow rate decreases  $\Delta p$  and  $\Delta p_o$  in the same proportion, and Eqs. (6-151) and (6-152) are still satisfied, preserving good distribution independent of flow rate, as long as friction losses remain small compared to inertial (velocity head change) effects. Conversely, increasing the flow rate through a distributor with severe maldistribution will not generally produce good distribution.

Often, the pressure drop required for design flow rate is unacceptably large for a distributor pipe designed for uniform velocity through uniformly sized and spaced orifices. Several measures may be taken in such situations. These include the following:

1. Taper the diameter of the distributor pipe so that the pipe velocity and velocity head remain constant along the pipe, thus substantially reducing pressure variation in the pipe.
2. Vary the hole size and/or the spacing between holes to compensate for the pressure variation along the pipe. This method may be sensitive to flow rate and a distributor optimized for one flow rate may suffer increased maldistribution as flow rate deviates from design rate.
3. Feed or withdraw from both ends, reducing the pipe flow velocity head and required hole pressure drop by a factor of 4.

The orifice discharge coefficient  $C_o$  is usually taken to be about 0.62. However,  $C_o$  is dependent on the ratio of hole diameter to pipe diameter, pipe wall thickness to hole diameter ratio, and pipe velocity to hole velocity ratio. As long as all these are small, the coefficient 0.62 is generally adequate.

**Example 9: Pipe Distributor** A 3-in schedule 40 (inside diameter 7.793 cm) pipe is to be used as a distributor for a flow of 0.010 m<sup>3</sup>/s of water ( $\rho = 1,000 \text{ kg/m}^3$ ,  $\mu = 0.001 \text{ Pa} \cdot \text{s}$ ). The pipe is 0.7 m long and is to have 10 holes of uniform diameter and spacing along the length of the pipe. The distributor pipe is submerged. Calculate the required hole size to limit maldistribution to 5 percent, and estimate the pressure drop across the distributor.

The inlet velocity computed from  $V_i = Q/A = 4Q/(\pi D^2)$  is 2.10 m/s, and the inlet Reynolds number is

$$Re = \frac{DV_i\rho}{\mu} = \frac{0.07793 \times 2.10 \times 1,000}{0.001} = 1.64 \times 10^5$$

For commercial pipe with roughness  $\epsilon = 0.046 \text{ mm}$ , the friction factor is about 0.0043. Approaching the last hole, the flow rate, velocity, and Reynolds number are about one-tenth their inlet values. At  $Re = 16,400$  the friction factor  $f$  is about 0.0070. Using an average value of  $f = 0.0057$  over the length of the pipe,  $4fL/3D$  is 0.068 and may reasonably be neglected so that Eq. (6-151) may be used. With  $C_o = 0.62$ ,

$$\frac{V_o}{V_i} = \frac{A_p}{A_o} = \sqrt{10C_o} = \sqrt{10} \times 0.62 = 1.96$$

With pipe cross-sectional area  $A_p = 0.00477 \text{ m}^2$ , the total hole area is  $0.00477/1.96 = 0.00243 \text{ m}^2$ . The area and diameter of each hole are then

$0.00243/10 = 0.000243 \text{ m}^2$  and 1.76 cm. With  $V_o/V_i = 1.96$ , the hole velocity is  $1.96 \times 2.10 = 4.12 \text{ m/s}$  and the pressure drop across the holes is obtained from Eq. (6-149).

$$\Delta p_o = \frac{1}{C_o^2} \frac{\rho V_o^2}{2} = \frac{1}{0.62^2} \times \frac{1,000(4.12)^2}{2} = 22,100 \text{ Pa}$$

Since the hole pressure drop is 10 times the pressure variation in the pipe, the total pressure drop from the inlet of the distributor may be taken as approximately 22,100 Pa.

Further detailed information on pipe distributors may be found in Senecal (*Ind. Eng. Chem.*, **49**, 993–997 [1957]). Much of the information on tapered manifold design has appeared in the pulp and paper literature (Spengos and Kaiser, *TAPPI*, **46**[3], 195–200 [1963]; Madeley, *Paper Technology*, **9**[1], 35–39 [1968]; Mardon, et al., *TAPPI*, **46**[3], 172–187 [1963]; Mardon, et al., *Pulp and Paper Magazine of Canada*, **72**[11], 76–81 [November 1971]; Truffitt, *TAPPI*, **58**[11], 144–145 [1975]).

**Slot Distributors** These are generally used in sheeting dies for extrusion of films and coatings and in air knives for control of thickness of a material applied to a moving sheet. A simple slotted pipe for turbulent flow conditions may give severe maldistribution because of nonuniform discharge velocity, but also because this type of design does not readily give perpendicular discharge (Koestel and Tuve, *Heat. Piping Air Cond.*, **20**[1], 153–157 [1948]; Senecal, *Ind. Eng. Chem.*, **49**, 993–997 [1957]; Koestel and Young, *Heat. Piping Air Cond.*, **23**[7], 111–115 [1951]). For slots in tapered ducts where the duct cross-sectional area decreases linearly to zero at the far end, the discharge angle will be constant along the length of the duct (Koestel and Young, *ibid.*). One way to ensure an almost perpendicular discharge is to have the ratio of the area of the slot to the cross-sectional area of the pipe equal to or less than 0.1. As in the case of perforated-pipe distributors, pressure variation within the slot manifold and pressure drop across the slot must be carefully considered.

In practice, the following methods may be used to keep the diameter of the pipe to a minimum consistent with good performance (Senecal, *Ind. Eng. Chem.*, **49**, 993–997 [1957]):

1. Feed from both ends.
2. Modify the cross-sectional design (Fig. 6-35); the slot is thus farther away from the influence of feed-stream velocity.
3. Increase pressure drop across the slot; this can be accomplished by lengthening the lips (Fig. 6-35).
4. Use screens (Fig. 6-35) to increase overall pressure drop across the slot.

Design considerations for air knives are discussed by Senecal (*ibid.*). Design procedures for extrusion dies when the flow is laminar, as with highly viscous fluids, are presented by Bernhardt (*Processing of Thermoplastic Materials*, Rheinhold, New York, 1959, pp. 248–281).

**Turning Vanes** In applications such as ventilation, the discharge profile from slots can be improved by turning vanes. The tapered duct is the most amenable for turning vanes because the discharge angle remains constant. One way of installing the vanes is shown in Fig. 6-36. The vanes should have a depth twice the spacing (*Heating, Ventilating, Air Conditioning Guide*, vol. 38, American Society of Heating, Refrigerating and Air-Conditioning Engineers, 1960, pp. 282–283) and a curvature at the upstream end of the vanes of a circular arc which is tangent to the discharge angle  $\theta$  of a slot without vanes and perpendicular at the downstream or discharge end of the vanes (Koestel and Young, *Heat. Piping Air Cond.*, **23**[7], 111–115 [1951]). Angle  $\theta$  can be estimated from

$$\cot \theta = \frac{C_d A_s}{A_d} \tag{6-153}$$

FIG. 6-35 Modified slot distributor.

FIG. 6-36 Turning vanes in a slot distributor.

where  $A_s$  = slot area  
 $A_d$  = duct cross-sectional area at upstream end  
 $C_d$  = discharge coefficient of slot

Vanes may be used to improve velocity distribution and reduce frictional loss in bends, when the ratio of bend turning radius to pipe diameter is less than 1.0. For a miter bend with low-velocity flows, simple circular arcs (Fig. 6-37) can be used, and with high-velocity flows, vanes of special airfoil shapes are required. For additional details and references, see Ower and Pankhurst (*The Measurement of Air Flow*, Pergamon, New York, 1977, p. 102); Pankhurst and Holder (*Wind-Tunnel Technique*, Pitman, London, 1952, pp. 92–93); Rouse (*Engineering Hydraulics*, Wiley, New York, 1950, pp. 399–401); and Jorgensen (*Fan Engineering*, 7th ed., Buffalo Forge Co., Buffalo, 1970, pp. 111, 117, 118).

**Perforated Plates and Screens** A nonuniform velocity profile in turbulent flow through channels or process equipment can be smoothed out to any desired degree by adding sufficient uniform resistance, such as perforated plates or screens across the flow channel, as shown in Fig. 6-38. Stoker (*Ind. Eng. Chem.*, **38**, 622–624 [1946]) provides the following equation for the effect of a uniform resistance on velocity profile:

$$\frac{V_{2,\max}}{V} = \sqrt{\frac{(V_{1,\max}/V)^2 + \alpha_2 - \alpha_1 + \alpha_2 K}{1 + K}} \quad (6-154)$$

Here,  $V$  is the area average velocity,  $K$  is the number of velocity heads of pressure drop provided by the uniform resistance,  $\Delta p = K\rho V^2/2$ , and  $\alpha$  is the velocity profile factor used in the mechanical energy balance, Eq. (6-13). It is the ratio of the area average of the cube of the velocity, to the cube of the area average velocity  $V$ . The shape of the exit velocity profile appears twice in Eq. (6-154), in  $V_{2,\max}/V$  and  $\alpha_2$ . Typically,  $K$  is on the order of 10, and the desired exit velocity profile

FIG. 6-37 Miter bend with vanes.

FIG. 6-38 Smoothing out a nonuniform profile in a channel.

is fairly uniform so that  $\alpha_2 \sim 1.0$  may be appropriate. Downstream of the resistance, the velocity profile will gradually reestablish the fully developed profile characteristic of the Reynolds number and channel shape. The screen or perforated plate open area required to produce the resistance  $K$  may be computed from Eqs. (6-107) or (6-111).

Screens and other flow restrictions may also be used to suppress stream swirl and turbulence (Loehrke and Nagib, *J. Fluids Eng.*, **98**, 342–353 [1976]). Contraction of the channel, as in a venturi, provides further reduction in turbulence level and flow nonuniformity.

**Beds of Solids** A suitable depth of solids can be used as a fluid distributor. As for other types of distribution devices, a pressure drop of 10 velocity heads is typically used, here based on the superficial velocity through the bed. There are several substantial disadvantages to use of particle beds for flow distribution. Heterogeneity of the bed may actually worsen rather than improve distribution. In general, uniform flow may be found only downstream of the point in the bed where sufficient pressure drop has occurred to produce uniform flow. Therefore, inefficiency results when the bed also serves reaction or mass transfer functions, as in catalysts, adsorbents, or tower packings for gas/liquid contacting, since portions of the bed are bypassed. In the case of trickle flow of liquid downward through column packings, inlet distribution is critical since the bed itself is relatively ineffective in distributing the liquid. Maldistribution of flow through packed beds also arises when the ratio of bed diameter to particle size is less than 10 to 30.

**Other Flow Straightening Devices** Other devices designed to produce uniform velocity or reduce swirl, sometimes with reduced pressure drop, are available. These include both commercial devices of proprietary design and devices discussed in the literature. For pipeline flows, see the references under flow inverters and static mixing elements previously discussed in the “Incompressible Flow in Pipes and Channels” subsection. For large area changes, as at the entrance to a vessel, it is sometimes necessary to diffuse the momentum of the inlet jet discharging from the feed pipe in order to produce a more uniform velocity profile within the vessel. Methods for this application exist, but remain largely in the domain of proprietary, commercial design.

## FLUID MIXING

Mixing of fluids is a discipline of fluid mechanics. Fluid motion is used to accelerate the otherwise slow processes of diffusion and conduction to bring about uniformity of concentration and temperature, blend materials, facilitate chemical reactions, bring about intimate contact of multiple phases, and so on. As the subject is too broad to cover fully, only a brief introduction and some references for further information are given here.

Several texts are available. These include Paul, Atiemo-Obeng, and Kresta (*Handbook of Industrial Mixing*, Wiley-Interscience, Hoboken N.J., 2004); Hamby, Edwards, and Nienow (*Mixing in the Process Industries*, 2d ed., Butterworths, London, 1992); Oldshue (*Fluid Mixing Technology*, McGraw-Hill, New York, 1983); Tatterson (*Fluid Mixing and Gas Dispersion in Agitated Tanks*, McGraw-Hill, New York, 1991); Uhl and Gray (*Mixing*, vols. I–III, Academic, New York, 1966, 1967, 1986); and Nagata (*Mixing: Principles and Applications*, Wiley, New York, 1975). A good overview of stirred tank agitation is given in the series of articles from *Chemical Engineering* (110–114, Dec. 8, 1975; 139–145, Jan. 5, 1976; 93–100, Feb. 2, 1976; 102–110,

FIG. 6-39 Typical stirred tank configurations, showing time-averaged flow patterns for axial flow and radial flow impellers. (From Oldshue, Fluid Mixing Technology, McGraw-Hill, New York, 1983.)

Apr. 26, 1976; 144-150, May 24, 1976; 141-148, July 19, 1976; 89-94, Aug. 2, 1976; 101-108, Aug. 30, 1976; 109-112, Sept. 27, 1976; 119-126, Oct. 25, 1976; 127-133, Nov. 8, 1976).

Process mixing is commonly carried out in pipeline and vessel geometries. The terms **radial mixing** and **axial mixing** are commonly used. Axial mixing refers to mixing of materials which pass a given point at different times, and thus leads to **backmixing**. For example, backmixing or axial mixing occurs in stirred tanks where fluid elements entering the tank at different times are intermingled.

Mixing of elements initially at different axial positions in a pipeline is axial mixing. Radial mixing occurs between fluid elements passing a given point at the same time, as, for example, between fluids mixing in a pipeline tee.

**Turbulent flow**, by means of the chaotic eddy motion associated with velocity fluctuation, is conducive to rapid mixing and, therefore, is the preferred flow regime for mixing. **Laminar mixing** is carried out when high viscosity makes turbulent flow impractical.

**Stirred Tank Agitation** Turbine impeller agitators, of a variety of shapes, are used for stirred tanks, predominantly in turbulent flow. Figure 6-39 shows typical stirred tank configurations and time-averaged flow patterns for axial flow and radial flow impellers. In order to prevent formation of a **vortex**, four vertical baffles are normally installed. These cause top-to-bottom mixing and prevent mixing-ineffective swirling motion.

For a given impeller and tank geometry, the impeller Reynolds number determines the flow pattern in the tank:

$$Re_i = \frac{D^2 N \rho}{\mu} \tag{6-155}$$

where  $D$  = impeller diameter,  $N$  = rotational speed, and  $\rho$  and  $\mu$  are the liquid density and viscosity. Rotational speed  $N$  is typically reported in revolutions per minute, or revolutions per second in SI units. Radians per second are almost never used. Typically,  $Re_i > 10^4$  is required for fully turbulent conditions throughout the tank. A wide transition region between laminar and turbulent flow occurs over the range  $10 < Re_i < 10^4$ .

The power  $P$  drawn by the impeller is made dimensionless in a group called the power number:

$$N_p = \frac{P}{\rho N^3 D^5} \tag{6-156}$$

Figure 6-40 shows power number vs. impeller Reynolds number for a typical configuration. The similarity to the friction factor vs. Reynolds number behavior for pipe flow is significant. In laminar flow, the power number is inversely proportional to Reynolds number, reflecting the dominance of viscous forces over inertial forces. In

FIG. 6-40 Dimensionless power number in stirred tanks. (Reprinted with permission from Bates, Fondy, and Corpstein, Ind. Eng. Chem. Process Design Develop., 2, 310 [1963].)

turbulent flow, where inertial forces dominate, the power number is nearly constant.

Impellers are sometimes viewed as pumping devices; the total volumetric flow rate  $Q$  discharged by an impeller is made dimensionless in a pumping number:

$$N_Q = \frac{Q}{ND^3} \quad (6-157)$$

Blend time  $t_b$ , the time required to achieve a specified maximum standard deviation of concentration after injection of a tracer into a stirred tank, is made dimensionless by multiplying by the impeller rotational speed:

$$N_b = t_b N \quad (6-158)$$

Dimensionless pumping number and blend time are independent of Reynolds number under fully turbulent conditions. The magnitude of concentration fluctuations from the final well-mixed value in batch mixing decays exponentially with time.

The design of mixing equipment depends on the desired process result. There is often a tradeoff between operating cost, which depends mainly on power, and capital cost, which depends on agitator size and torque. For some applications bulk flow throughout the vessel is desired, while for others high local turbulence intensity is required. Multiphase systems introduce such design criteria as solids suspension and gas dispersion. In very viscous systems, helical ribbons, extruders, and other specialized equipment types are favored over turbine agitators.

**Pipeline Mixing** Mixing may be carried out with **mixing tees, inline or motionless mixing elements**, or in empty pipe. In the latter case, large pipe lengths may be required to obtain adequate mixing. Coaxially injected streams require lengths on the order of 100 pipe diameters. Coaxial mixing in turbulent single-phase flow is characterized by the turbulent diffusivity (eddy diffusivity)  $D_E$  which determines the rate of radial mixing. Davies (*Turbulence Phenomena*, Academic, New York, 1972) provides an equation for  $D_E$  which may be rewritten as

$$D_E \sim 0.015DV\text{Re}^{-0.125} \quad (6-159)$$

where  $D$  = pipe diameter  
 $V$  = average velocity  
 $\text{Re}$  = pipe Reynolds number,  $DV\rho/\mu$   
 $\rho$  = density  
 $\mu$  = viscosity

Properly designed tee mixers, with due consideration given to main stream and injected stream momentum, are capable of producing high degrees of uniformity in just a few diameters. Fomey (*Jet Injection for Optimum Pipeline Mixing*, in "Encyclopedia of Fluid Mechanics," vol. 2., Chap. 25, Gulf Publishing, 1986) provides a thorough discussion of tee mixing. Inline or motionless mixers are generally of proprietary commercial design, and may be selected for viscous or turbulent, single or multiphase mixing applications. They substantially reduce required pipe length for mixing.

## TUBE BANKS

Pressure drop across tube banks may not be correlated by means of a single, simple friction factor—Reynolds number curve, owing to the variety of tube configurations and spacings encountered, two of which are shown in Fig. 6-41. Several investigators have allowed for configuration and spacing by incorporating spacing factors in their friction factor expressions or by using multiple friction factor plots. Commercial computer codes for heat-exchanger design are available which include features for estimating pressure drop across tube banks.

**Turbulent Flow** The correlation by Grimson (*Trans. ASME*, **59**, 583–594 [1937]) is recommended for predicting pressure drop for turbulent flow ( $\text{Re} \geq 2,000$ ) across staggered or in-line tube banks for tube spacings  $[(a/D_i), (b/D_i)]$  ranging from 1.25 to 3.0. The pressure drop is given by

$$\Delta p = \frac{4fN_r\rho V_{\max}^2}{2} \quad (6-160)$$

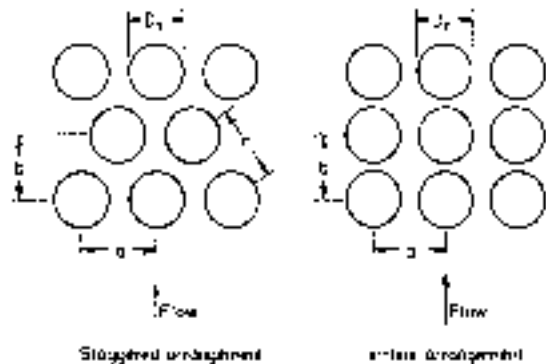

FIG. 6-41 Tube-bank configurations.

where  $f$  = friction factor  
 $N_r$  = number of rows of tubes in the direction of flow  
 $\rho$  = fluid density  
 $V_{\max}$  = fluid velocity through the minimum area available for flow

For banks of **staggered tubes**, the friction factor for isothermal flow is obtained from Fig. (6-42). Each "fence" (group of parametric curves) represents a particular Reynolds number defined as

$$\text{Re} = \frac{D_i V_{\max} \rho}{\mu} \quad (6-161)$$

where  $D_i$  = tube outside diameter and  $\mu$  = fluid viscosity. The numbers along each fence represent the transverse and inflow-direction spacings. The upper chart is for the case in which the minimum area for flow is in the transverse openings, while the lower chart is for the case in which the minimum area is in the diagonal openings. In the latter case,  $V_{\max}$  is based on the area of the diagonal openings and  $N_r$  is the number of rows in the direction of flow minus 1. A critical comparison of this method with all the data available at the time showed an average deviation of the order of  $\pm 15$  percent (Boucher and Lapple, *Chem. Eng. Prog.*, **44**, 117–134 [1948]). For tube spacings greater than 3 tube diameters, the correlation by Gunter and Shaw (*Trans. ASME*, **67**, 643–660 [1945]) can be used as an approximation. As an **approximation**, the pressure drop can be taken as 0.72 velocity head (based on  $V_{\max}$  per row of tubes for tube spacings commonly encountered in practice (Lapple, et al., *Fluid and Particle Mechanics*, University of Delaware, Newark, 1954).

For banks of **in-line tubes**,  $f$  for isothermal flow is obtained from Fig. 6-43. Average deviation from available data is on the order of  $\pm 15$  percent. For tube spacings greater than  $3D_i$ , the charts of Gram, Mackey, and Monroe (*Trans. ASME*, **80**, 25–35 [1958]) can be used. As an **approximation**, the pressure drop can be taken as 0.32 velocity head (based on  $V_{\max}$ ) per row of tubes (Lapple, et al., *Fluid and Particle Mechanics*, University of Delaware, Newark, 1954).

For turbulent flow through **shallow** tube banks, the average friction factor per row will be somewhat greater than indicated by Figs. 6-42 and 6-43, which are based on 10 or more rows depth. A 30 percent increase per row for 2 rows, 15 percent per row for 3 rows, and 7 percent per row for 4 rows can be taken as the maximum likely to be encountered (Boucher and Lapple, *Chem. Eng. Prog.*, **44**, 117–134 [1948]).

For a **single row of tubes**, the friction factor is given by Curve B in Fig. 6-44 as a function of tube spacing. This curve is based on the data of several experimenters, all adjusted to a Reynolds number of 10,000. The values should be substantially independent of  $\text{Re}$  for  $1,000 < \text{Re} < 100,000$ .

For **extended surfaces**, which include fins mounted perpendicularly to the tubes or spiral-wound fins, pin fins, plate fins, and so on, friction data for the specific surface involved should be used. For

FIG. 6-42 Upper chart: Friction factors for staggered tube banks with minimum fluid flow area in transverse openings. Lower chart: Friction factors for staggered tube banks with minimum fluid flow area in diagonal openings. (From Grimson, *Trans. ASME*, 59, 583 [1937].)

details, see Kays and London (*Compact Heat Exchangers*, 2d ed., McGraw-Hill, New York, 1964). If specific data are unavailable, the correlation by Gunter and Shaw (*Trans. ASME*, 67, 643-660 [1945]) may be used as an approximation.

When a large temperature change occurs in a gas flowing across a tube bundle, gas properties should be evaluated at the mean temperature

$$T_m = T_t + K \Delta T_{lm} \tag{6-162}$$

where  $T_t$  = average tube-wall temperature  
 $K$  = constant

$\Delta T_{lm}$  = log-mean temperature difference between the gas and the tubes

Values of  $K$  averaged from the recommendations of Chilton and Genereaux (*Trans. AIChE*, 29, 151-173 [1933]) and Grimson (*Trans. ASME*, 59, 583-594 [1937]) are as follows: for in-line tubes, 0.9 for cooling and -0.9 for heating; for staggered tubes, 0.75 for cooling and -0.8 for heating.

For nonisothermal flow of **liquids** across tube bundles, the friction factor is increased if the liquid is being cooled and decreased if the liquid is being heated. The factors previously given for nonisothermal

flow of liquids in pipes ("Incompressible Flow in Pipes and Channels") should be used.

For two-phase gas/liquid horizontal cross flow through tube banks, the method of Diehl and Unruh (*Pet. Refiner*, 37[10], 124-128 [1958]) is available.

**Transition Region** This region extends roughly over the range  $200 < Re < 2,000$ . Figure 6-45 taken from Bergelin, Brown, and Doberstein (*Trans. ASME*, 74, 953-960 [1952]) gives curves for friction factor  $f_T$  for five different configurations. Pressure drop for liquid flow is given by

$$\Delta p = \frac{4f_T N_r \rho V_{max}^2}{2} \left( \frac{\mu_s}{\mu_b} \right)^{0.14} \tag{6-163}$$

where  $N_r$  = number of major restrictions encountered in flow through the bank (equal to number of rows when minimum flow area occurs in transverse openings, and to number of rows minus 1 when it occurs in the diagonal openings);  $\rho$  = fluid density;  $V_{max}$  = velocity through minimum flow area;  $\mu_s$  = fluid viscosity at tube-surface temperature and  $\mu_b$  = fluid viscosity at average bulk temperature. This method gives the friction factor within about  $\pm 25$  percent.

**Laminar Region** Bergelin, Colburn, and Hull (*Univ. Delaware Eng. Exp. Sta. Bull.*, 2 [1950]) recommend the following equations for

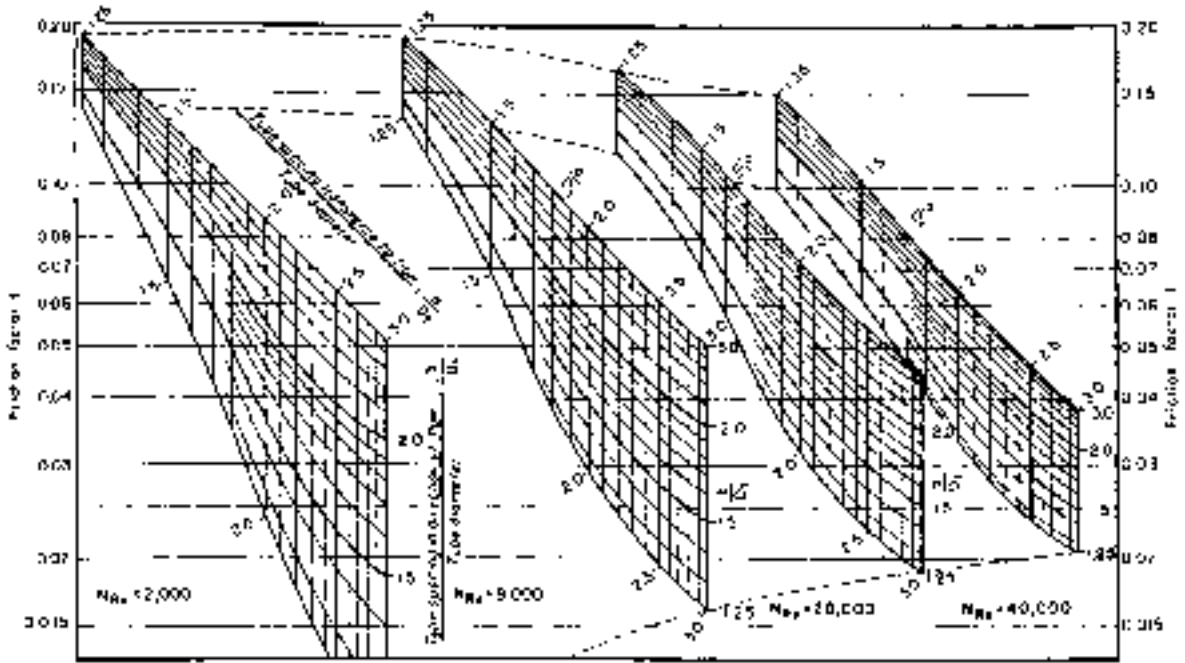

FIG. 6-43 Friction factors for in-line tube banks. (From Grimson, Trans. ASME, 59, 583 [1937].)

pressure drop with laminar flow ( $Re_v < 100$ ) of liquids across banks of plain tubes with pitch ratios  $P/D$ , of 1.25 and 1.50:

$$\Delta p = \frac{280N_r}{Re_v} \left(\frac{D_r}{P}\right)^{1.6} \left(\frac{\mu_s}{\mu_b}\right)^m \left(\frac{\rho V_{max}^2}{2}\right) \quad (6-164)$$

$$m = \frac{0.57}{(Re_v)^{0.25}} \quad (6-165)$$

where  $Re_v = D_v V_{max} \rho / \mu_b$ ;  $D_v$  = volumetric hydraulic diameter [(4 × free-bundle volume)/(exposed surface area of tubes)];  $P$  = pitch (=  $a$  for in-line arrangements, =  $a$  or  $c$  [whichever is smaller] for staggered

arrangements), and other quantities are as defined following Eq. (6-163). Bergelin, et al. (ibid.) show that pressure drop per row is independent of the number of rows in the bank with laminar flow. The pressure drop is predicted within about ±25 percent.

FIG. 6-44 Friction factors vs. transverse spacing for single row of tubes. (From Boucher and Lapple, Chem. Eng. Prog., 44, 117 [1948].)

FIG. 6-45 Friction factors for transition region flow across tube banks. (Pitch is the minimum center-to-center tube spacing.) (From Bergelin, Brown, and Doberstein, Trans. ASME, 74, 953 [1952].)

FIG. 6-46 Friction factor for beds of solids. (From Leva, Fluidization, McGraw-Hill, New York, 1959, p. 49.)

The validity of extrapolating Eq. (6-164) to pitch ratios larger than 1.50 is unknown. The correlation of Gunter and Shaw (*Trans. ASME*, **67**, 643–660 [1945]) may be used as an approximation in such cases.

For laminar flow of non-Newtonian fluids across tube banks, see Adams and Bell (*Chem. Eng. Prog.*, **64**, *Symp. Ser.*, **82**, 133–145 [1968]).

Flow-induced **tube vibration** occurs at critical fluid velocities through tube banks, and is to be avoided because of the severe damage that can result. Methods to predict and correct vibration problems may be found in Eisinger (*Trans. ASME J. Pressure Vessel Tech.*, **102**, 138–145 [May 1980]) and Chen (*J. Sound Vibration*, **93**, 439–455 [1984]).

**BEDS OF SOLIDS**

**Fixed Beds of Granular Solids** Pressure-drop prediction is complicated by the variety of granular materials and of their packing arrangement. For flow of a **single incompressible fluid** through an incompressible bed of granular solids, the pressure drop may be estimated by the correlation given in Fig. 6-46 (Leva, *Chem. Eng.*, **56**[5], 115–117 [1949]), or *Fluidization*, McGraw-Hill, New York, 1959). The modified friction factor and Reynolds number are defined by

$$f_m \equiv \frac{D_p \rho \phi_s^{3-n} \epsilon^3 |\Delta p|}{2G^2 L (1-\epsilon)^{3-n}} \tag{6-166}$$

$$Re' \equiv \frac{D_p G}{\mu} \tag{6-167}$$

- where  $-\Delta p$  = pressure drop
- $L$  = depth of bed
- $D_p$  = average particle diameter, defined as the diameter of a sphere of the same volume as the particle
- $\epsilon$  = void fraction
- $n$  = exponent given in Fig. 6-46 as a function of  $Re'$
- $\phi_s$  = shape factor defined as the area of sphere of diameter  $D_p$  divided by the actual surface area of the particle
- $G$  = fluid superficial mass velocity based on the empty chamber cross section
- $\rho$  = fluid density
- $\mu$  = fluid viscosity

As for any incompressible single-phase flow, the equivalent pressure  $P = p + \rho gz$  where  $g$  = acceleration of gravity  $z$  = elevation, may be used in place of  $p$  to account for gravitational effects in flows with vertical components.

In creeping flow ( $Re' < 10$ ),

$$f_m = \frac{100}{Re'} \tag{6-168}$$

At high Reynolds numbers the friction factor becomes nearly constant, approaching a value of the order of unity for most packed beds.

In terms of  $S$ , particle surface area per unit volume of bed,

$$D_p = \frac{6(1-\epsilon)}{\phi_s S} \tag{6-169}$$

**Porous Media** Packed beds of granular solids are one type of the general class referred to as **porous media**, which include geological formations such as petroleum reservoirs and aquifers, manufactured materials such as sintered metals and porous catalysts, burning coal or char particles, and textile fabrics, to name a few. Pressure drop for incompressible flow across a porous medium has the same qualitative behavior as that given by Leva's correlation in the preceding. At low Reynolds numbers, viscous forces dominate and pressure drop is proportional to fluid viscosity and superficial velocity, and at high Reynolds numbers, pressure drop is proportional to fluid density and to the square of superficial velocity.

Creeping flow ( $Re' \ll 1$ ) through porous media is often described in terms of the **permeability**  $k$  and Darcy's law:

$$\frac{-\Delta P}{L} = \frac{\mu}{k} V \tag{6-170}$$

where  $V$  = superficial velocity. The SI units for permeability are  $m^2$ . Creeping flow conditions generally prevail in geological porous media. For **multidimensional flows** through **isotropic** porous media, the superficial velocity  $\mathbf{V}$  and pressure gradient  $\nabla P$  vectors replace the corresponding one-dimensional variables in Eq. (6-170).

$$\nabla P = -\frac{\mu}{k} \mathbf{V} \tag{6-171}$$

For isotropic homogeneous porous media (uniform permeability and porosity), the pressure for creeping incompressible single phase-flow may be shown to satisfy the Laplace equation:

$$\nabla^2 p = 0 \quad (6-172)$$

For **anisotropic** or **oriented** porous media, as are frequently found in geological media, permeability varies with direction and a **permeability tensor**  $\mathbf{K}$ , with nine components  $K_{ij}$  giving the velocity component in the  $i$  direction due to a pressure gradient in the  $j$  direction, may be introduced. For further information, see Slattery (*Momentum, Energy and Mass Transfer in Continua*, Krieger, Huntington, New York, 1981, pp. 193–218). See also Dullien (*Chem. Eng. J. [Lausanne]*, **10**, 1,034 [1975]) for a review of pressure-drop methods in single-phase flow. Solutions for Darcy's law for several geometries of interest in petroleum reservoirs and aquifers, for both incompressible and compressible flows, are given in Craft and Hawkins (*Applied Petroleum Reservoir Engineering*, Prentice-Hall, Englewood Cliffs, N.J., 1959). See also Todd (*Groundwater Hydrology*, 2nd ed., Wiley, New York, 1980).

For granular solids of **mixed sizes** the average particle diameter may be calculated as

$$\frac{1}{D_p} = \sum_i \frac{x_i}{D_{p,i}} \quad (6-173)$$

where  $x_i$  = weight fraction of particles of size  $D_{p,i}$ .

For **isothermal compressible flow** of a gas with constant compressibility factor  $Z$  through a packed bed of granular solids, an equation similar to Eq. (6-114) for pipe flow may be derived:

$$p_1^2 - p_2^2 = \frac{2ZRC^2T}{M_w} \left[ \ln \frac{v_2}{v_1} + \frac{2f_m L(1-\epsilon)^{3-n}}{\phi_s^{3-n} \epsilon^3 D_p} \right] \quad (6-174)$$

where  $p_1$  = upstream absolute pressure  
 $p_2$  = downstream absolute pressure  
 $R$  = gas constant  
 $T$  = absolute temperature  
 $M_w$  = molecular weight  
 $v_1$  = upstream specific volume of gas  
 $v_2$  = downstream specific volume of gas

For creeping flow of **power law** non-Newtonian fluids, the method of Christopher and Middleton (*Ind. Eng. Chem. Fundam.*, **4**, 422–426 [1965]) may be used:

$$-\Delta p = \frac{150HLV^n(1-\epsilon)^2}{D_p^2 \phi_s^2 \epsilon^3} \quad (6-175)$$

$$H = \frac{K}{12} \left( 9 + \frac{3}{n} \right)^n \left[ \frac{D_p^2 \phi_s^2 \epsilon^4}{(1-\epsilon)^2} \right]^{(1-n)/2} \quad (6-176)$$

where  $V = G/\rho$  = superficial velocity,  $K$ ,  $n$  = power law material constants, and all other variables are as defined in Eq. (6-166). This correlation is supported by data from Christopher and Middleton (*ibid.*), Gregory and Griskey (*AIChE J.*, **13**, 122–125 [1967]), Yu, Wen, and Bailie (*Can. J. Chem. Eng.*, **46**, 149–154 [1968]), Siskovic, Gregory, and Griskey (*AIChE J.*, **17**, 176–187 [1978]), Kemplowski and Merl (*Chem. Eng. Sci.*, **29**, 213–223 [1974]), and Kemplowski and Dziubinski (*Rheol. Acta*, **17**, 176–187 [1978]). The measurements cover the range  $n = 0.50$  to  $1.60$ , and modified Reynolds number  $Re' = 10^{-8}$  to  $10$ , where

$$Re' = \frac{D_p V^{2-n} \rho}{H} \quad (6-177)$$

For the case  $n = 1$  (Newtonian fluid), Eqs. (6-175) and (6-176) give a pressure drop 25 percent less than that given by Eqs. (6-166) through (6-168).

For **viscoelastic fluids** see Marshall and Metzner (*Ind. Eng. Chem. Fundam.*, **6**, 393–400 [1967]), Siskovic, Gregory, and Griskey (*AIChE J.*, **13**, 122–125 [1967]) and Kemplowski and Dziubinski (*Rheol. Acta*, **17**, 176–187 [1978]).

For gas flow through porous media with small pore diameters, the slip flow and molecular flow equations previously given (see the "Vacuum Flow" subsection) may be applied when the pore is of the same or

smaller order as the mean free path, as described by Monet and Vermeulen (*Chem. Eng. Prog.*, **55**, *Symp. Ser.*, **25** [1959]).

**Tower Packings** For the flow of a **single fluid** through a bed of tower packing, pressure drop may be estimated using the preceding methods. See also Sec. 14 of this *Handbook*. For **countercurrent gas/liquid flow** in commercial tower packings, both structured and unstructured, several sources of data and correlations for pressure drop and flooding are available. See, for example, Strigle (*Random Packings and Packed Towers, Design and Applications*, Gulf Publishing, Houston, 1989; *Chem. Eng. Prog.*, **89**[8], 79–83 [August 1993]), Hughmark (*Ind. Eng. Chem. Fundam.*, **25**, 405–409 [1986]), Chen (*Chem. Eng. Sci.*, **40**, 2139–2140 [1985]), Billet and Mackowiak (*Chem. Eng. Technol.*, **11**, 213–217 [1988]), Krehenwinkel and Knapp (*Chem. Eng. Technol.*, **10**, 231–242 [1987]), Mersmann and Deixler (*Ger. Chem. Eng.*, **9**, 265–276 [1986]), and Robbins (*Chem. Eng. Progr.*, **87**[5], 87–91 [May 1991]). Data and correlations for flooding and pressure drop for structured packings are given by Fair and Bravo (*Chem. Eng. Progr.*, **86**[1], 19–29 [January 1990]).

**Fluidized Beds** When gas or liquid flows upward through a vertically unconstrained bed of particles, there is a minimum fluid velocity at which the particles will begin to move. Above this minimum velocity, the bed is said to be **fluidized**. Fluidized beds are widely used, in part because of their excellent mixing and heat and mass transfer characteristics. See Sec. 17 of this *Handbook* for detailed information.

## BOUNDARY LAYER FLOWS

Boundary layer flows are a special class of flows in which the flow far from the surface of an object is inviscid, and the effects of viscosity are manifest only in a thin region near the surface where steep velocity gradients occur to satisfy the no-slip condition at the solid surface. The thin layer where the velocity decreases from the inviscid, potential flow velocity to zero (relative velocity) at the solid surface is called the **boundary layer**. The thickness of the boundary layer is indefinite because the velocity asymptotically approaches the free-stream velocity at the outer edge. The boundary layer thickness is conventionally taken to be the distance for which the velocity equals 0.99 times the free-stream velocity. The boundary layer may be either laminar or turbulent. Particularly in the former case, the equations of motion may be simplified by scaling arguments. Schlichting (*Boundary Layer Theory*, 8th ed., McGraw-Hill, New York, 1987) is the most comprehensive source for information on boundary layer flows.

**Flat Plate, Zero Angle of Incidence** For flow over a wide, thin flat plate at zero angle of incidence with a uniform free-stream velocity, as shown in Fig. 6-47, the **critical Reynolds number** at which the boundary layer becomes turbulent is normally taken to be

$$Re_x = \frac{xV\rho}{\mu} = 500,000 \quad (6-178)$$

where  $V$  = free-stream velocity  
 $\rho$  = fluid density  
 $\mu$  = fluid viscosity  
 $x$  = distance from leading edge of the plate

### Uniform free-stream velocity

FIG. 6-47 Boundary layer on a flat plate at zero angle of incidence.

However, the transition Reynolds number depends on free-stream turbulence and may range from  $3 \times 10^5$  to  $3 \times 10^6$ . The **laminar boundary layer** thickness  $\delta$  is a function of distance from the leading edge:

$$\delta \approx 5.0x\text{Re}_x^{-0.5} \quad (6-179)$$

The total drag on the plate of length  $L$  and width  $b$  for a laminar boundary layer, including the drag on both surfaces, is:

$$F_D = 1.328bL\rho V^2\text{Re}_L^{-0.5} \quad (6-180)$$

For **non-Newtonian power law fluids** (Acrivos, Shah, and Peterson, *AIChE J.*, **6**, 312–317 [1960]; Hsu, *AIChE J.*, **15**, 367–370 [1969]),

$$F_D = CbL\rho V^2\text{Re}_L^{-1/(1+n)} \quad (6-181)$$

|       |       |       |       |       |       |       |       |       |       |
|-------|-------|-------|-------|-------|-------|-------|-------|-------|-------|
| $n =$ | 0.2   | 0.3   | 0.4   | 0.5   | 0.6   | 0.7   | 0.8   | 0.9   | 1     |
| $C =$ | 2.075 | 1.958 | 1.838 | 1.727 | 1.627 | 1.538 | 1.460 | 1.390 | 1.328 |

where  $\text{Re}'_L = \rho V^{2-n}L^n/K$  and  $K$  and  $n$  are the power law material constants (see Eq. [6-4]).

For a **turbulent boundary layer**, the thickness may be estimated as

$$\delta \approx 0.37x\text{Re}_x^{-0.2} \quad (6-182)$$

and the total drag force on both sides of the plate of length  $L$  is

$$F_D = \left[ \frac{0.455}{(\log \text{Re}_L)^{2.58}} - \frac{1,700}{\text{Re}_L} \right] \rho bLV^2 \quad 5 \times 10^5 < \text{Re}_L < 10^9 \quad (6-183)$$

Here the second term accounts for the laminar leading edge of the boundary layer and assumes that the critical Reynolds number is 500,000.

**Cylindrical Boundary Layer** Laminar boundary layers on cylindrical surfaces, with flow parallel to the cylinder axis, are described by Glauert and Lighthill (*Proc. R. Soc. [London]*, **230A**, 188–203 [1955]), Jaffe and Okamura (*Z. Angew. Math. Phys.*, **19**, 564–574 [1968]), and Stewartson (*Q. Appl. Math.*, **13**, 113–122 [1955]). For a turbulent boundary layer, the total drag may be estimated as

$$F_D = \bar{c}_f \pi r L \rho V^2 \quad (6-184)$$

where  $r$  = cylinder radius,  $L$  = cylinder length, and the average friction coefficient is given by (White, *J. Basic Eng.*, **94**, 200–206 [1972])

$$\bar{c}_f = 0.0015 + \left[ 0.30 + 0.015 \left( \frac{L}{r} \right)^{0.4} \right] \text{Re}_L^{-1/3} \quad (6-185)$$

for  $\text{Re}_L = 10^6$  to  $10^9$  and  $L/r < 10^6$ .

**Continuous Flat Surface** Boundary layers on continuous surfaces drawn through a stagnant fluid are shown in Fig. 6-48. Figure 6-48a shows the continuous flat surface (Sakiadis, *AIChE J.*, **7**, 26–28,

**FIG. 6-48** Continuous surface: (a) continuous flat surface, (b) continuous cylindrical surface. (From Sakiadis, *Am. Inst. Chem. Eng. J.*, **7**, 221, 467 [1961].)

221–225, 467–472 [1961]). The critical Reynolds number for transition to turbulent flow may be greater than the 500,000 value for the finite flat-plate case discussed previously (Tsou, Sparrow, and Kurtz, *J. Fluid Mech.*, **26**, 145–161 [1966]). For a laminar boundary layer, the thickness is given by

$$\delta = 6.37x\text{Re}_x^{-0.5} \quad (6-186)$$

and the total drag exerted on the two surfaces is

$$F_D = 1.776bL\rho V^2\text{Re}_L^{-0.5} \quad (6-187)$$

The total flow rate of fluid entrained by the surface is

$$q = 3.232bLV\text{Re}_L^{-0.5} \quad (6-188)$$

The theoretical velocity field was experimentally verified by Tsou, Sparrow, and Goldstein (*Int. J. Heat Mass Transfer*, **10**, 219–235 [1967]) and Szeri, Yates, and Hai (*J. Lubr. Technol.*, **98**, 145–156 [1976]). For **non-Newtonian power law fluids** see Fox, Erickson, and Fan (*AIChE J.*, **15**, 327–333 [1969]).

For a turbulent boundary layer, the thickness is given by

$$\delta = 1.01x\text{Re}_x^{-0.2} \quad (6-189)$$

and the total drag on both sides by

$$F_D = 0.056bL\rho V^2\text{Re}_L^{-0.2} \quad (6-190)$$

and the total entrainment by

$$q = 0.252bLV\text{Re}_L^{-0.2} \quad (6-191)$$

When the laminar boundary layer is a significant part of the total length of the object, the total drag should be corrected by subtracting a calculated turbulent drag for the length of the laminar section and then adding the laminar drag for the laminar section. Tsou, Sparrow, and Goldstein (*Int. J. Heat Mass Transfer*, **10**, 219–235 [1967]) give an improved analysis of the turbulent boundary layer; their data indicate that Eq. (6-190) underestimates the drag by about 15 percent.

**Continuous Cylindrical Surface** The continuous surface shown in Fig. 6-48b is applicable, for example, for a wire drawn through a stagnant fluid (Sakiadis, *AIChE J.*, **7**, 26–28, 221–225, 467–472 [1961]; Vasudevan and Middleman, *AIChE J.*, **16**, 614 [1970]). The critical-length Reynolds number for transition is  $\text{Re}_x = 200,000$ . The laminar boundary layer thickness, total drag, and entrainment flow rate may be obtained from Fig. 6-49. The normalized boundary layer thickness and integral friction coefficient are from Vasudevan and Middleman, who used a similarity solution of the boundary layer equations. The drag force over a length  $x$  is given by

$$F_D = \bar{C}_f x \frac{\rho V^2}{2} 2\pi r_o \quad (6-192)$$

The entrainment flow rate is from Sakiadis, who used an integral momentum approximation rather than the exact similarity solution.

$$q = V\Delta \quad (6-193)$$

Further laminar boundary layer analysis is given by Crane (*Z. Angew. Math. Phys.*, **23**, 201–212 [1972]).

For a turbulent boundary layer, the total drag may be roughly estimated using Eqs. (6-184) and (6-185) for finite cylinders. Measured forces by Kwon and Prevorsek (*J. Eng. Ind.*, **101**, 73–79 [1979]) are greater than predicted this way.

The laminar boundary layer on **deforming continuous surfaces** with velocity varying with axial position is discussed by Vleggaar (*Chem. Eng. Sci.*, **32**, 1517–1525 [1977]) and Crane (*Z. Angew. Math. Phys.*, **26**, 619–622 [1975]).

**VORTEX SHEDDING**

When fluid flows past objects or through orifices or similar restrictions, vortices may periodically be shed downstream. Objects such as smokestacks, chemical-processing columns, suspended pipelines, and electrical transmission lines can be subjected to damaging vibrations and forces due to the vortices, especially if the shedding frequency is close to a natural vibration frequency of the object. The shedding can

**FIG 6-49** Boundary layer parameters for continuous cylindrical surfaces. ( $\Delta/\pi r_o^2$  is from Sakiadis, *Am. Inst. Chem. Engr. J.*, **7**, 467 [1961];  $C_D x/2r_o$ , and  $\delta/r_o$  are from Vasudevan and Middleman, *Am. Inst. Chem. Eng. J.*, **16**, 614 [1970].)

also produce sound. See Krzywoblocki (*Appl. Mech. Rev.*, **6**, 393–397 [1953]) and Marris (*J. Basic Eng.*, **86**, 185–196 [1964]).

Development of a vortex street, or *von Kármán vortex street* is shown in Fig. 6-50. Discussions of the vortex street may be found in Panton (pp. 387–393). The Reynolds number is

$$Re = \frac{DV\rho}{\mu} \tag{6-194}$$

where  $D$  = diameter of cylinder or effective width of object  
 $V$  = free-stream velocity  
 $\rho$  = fluid density  
 $\mu$  = fluid viscosity

For flow past a cylinder, the vortex street forms at Reynolds numbers above about 40. The vortices initially form in the wake, the point of formation moving closer to the cylinder as  $Re$  is increased. At a Reynolds number of 60 to 100, the vortices are formed from eddies attached to the cylinder surface. The vortices move at a velocity slightly less than  $\bar{V}$ . The frequency of vortex shedding  $f$  is given in terms of the Strouhal number, which is approximately constant over a wide range of Reynolds numbers.

$$St \equiv \frac{fD}{V} \tag{6-195}$$

**FIG. 6-50** Vortex street behind a cylinder.

For  $40 < Re < 200$  the vortices are laminar and the Strouhal number has a nearly constant value of 0.2 for flow past a cylinder. Between  $Re = 200$  and 400 the Strouhal number is no longer constant and the wake becomes irregular. Above about  $Re = 400$  the vortices become turbulent, the wake is once again stable, and the Strouhal number remains constant at about 0.2 up to a Reynolds number of about  $10^5$ . Above  $Re = 10^5$  the vortex shedding is difficult to see in flow visualization experiments, but velocity measurements still show a strong spectral component at  $St = 0.2$  (Panton, p. 392). Experimental data suggest that the vortex street disappears over the range  $5 \times 10^5 < Re < 3.5 \times 10^6$ , but is reestablished at above  $3.5 \times 10^6$  (Schlichting).

Vortex shedding exerts alternating lateral forces on a cylinder, perpendicular to the flow direction. Such forces may lead to severe vibration or mechanical failure of cylindrical elements such as heat-exchanger tubes, transmission lines, stacks, and columns when the vortex shedding frequency is close to resonant bending frequency. According to Den Hartog (*Proc. Nat. Acad. Sci.*, **40**, 155–157 [1954]), the vortex shedding and cylinder vibration frequency will shift to the resonant frequency when the calculated shedding frequency is within 20 percent of the resonant frequency. The well-known Tacoma Narrows bridge collapse resulted from resonance between a torsional oscillation and vortex shedding (Panton, p. 392). Spiral strakes are sometimes installed on tall stacks so that vortices at different axial positions are not shed simultaneously. The alternating lateral force  $F_K$ , sometimes called the *von Kármán force*, is given by (Den Hartog, *Mechanical Vibrations*, 4th ed., McGraw-Hill, New York, 1956, pp. 305–309):

$$F_K = C_K A \frac{\rho V^2}{2} \tag{6-196}$$

where  $C_K$  = von Kármán coefficient  
 $A$  = projected area perpendicular to the flow  
 $\rho$  = fluid density  
 $V$  = free-stream fluid velocity

For a cylinder,  $C_K = 1.7$ . For a vibrating cylinder, the effective projected area exceeds, but is always less than twice, the actual cylinder projected area (Rouse, *Engineering Hydraulics*, Wiley, New York, 1950).

The following references pertain to discussions of vortex shedding in specific structures: steel stacks (Osler and Smith, *Trans. ASME*, **78**, 1381–1391 [1956]; Smith and McCarthy, *Mech. Eng.*, **87**, 38–41 [1965]); chemical-processing columns (Freese, *J. Eng. Ind.*, **81**, 77–91 [1959]); heat exchangers (Eisinger, *Trans. ASME J. Pressure Vessel Tech.*, **102**, 138–145 [May 1980]; Chen, *J. Sound Vibration*, **93**, 439–455 [1984]; Gainsboro, *Chem. Eng. Prog.*, **64**[3], 85–88 [1968]; “Flow-Induced Vibration in Heat Exchangers,” *Symp. Proc.*, ASME, New York, 1970); suspended pipe lines (Baird, *Trans. ASME*, **77**, 797–804 [1955]); and suspended cable (Steidel, *J. Appl. Mech.*, **23**, 649–650 [1956]).

**COATING FLOWS**

In coating flows, liquid films are entrained on moving solid surfaces. For general discussions, see Ruschak (*Ann. Rev. Fluid Mech.*, **17**, 65–89 [1985]), Cohen and Gutoff (*Modern Coating and Drying Technology*, VCH Publishers, New York, 1992), and Middleman (*Fundamentals of Polymer Processing*, McGraw-Hill, New York, 1977). It is generally important to control the thickness and uniformity of the coatings.

In **dip coating**, or free withdrawal coating, a solid surface is withdrawn from a liquid pool, as shown in Fig. 6-51. It illustrates many of the features found in other coating flows, as well. Tallmadge and Gutfinger (*Ind. Eng. Chem.*, **59**[11], 19–34 [1967]) provide an early review of the theory of dip coating. The coating flow rate and film thickness are controlled by the withdrawal rate and the flow behavior in the meniscus region. For a withdrawal velocity  $V$  and an angle of inclination from the horizontal  $\phi$ , the film thickness  $h$  may be

FIG. 6-51 Dip coating.

estimated for low withdrawal velocities by

$$h \left( \frac{\rho g}{\sigma} \right)^{1/2} = \frac{0.944}{(1 - \cos \phi)^{1/2}} Ca^{2/3} \quad (6-197)$$

where  $g$  = acceleration of gravity  
 $Ca = \mu V / \sigma$  = capillary number  
 $\mu$  = viscosity  
 $\sigma$  = surface tension

Equation (6-197) is asymptotically valid as  $Ca \rightarrow 0$  and agrees with experimental data up to capillary numbers in the range of 0.01 to 0.03. In practice, where high production rates require high withdrawal speeds, capillary numbers are usually too large for Eq. (6-197) to apply. Approximate analytical methods for larger capillary numbers have been obtained by numerous investigators, but none appears wholly satisfactory, and some are based on questionable assumptions (Ruschak, *Ann. Rev. Fluid Mech.*, **17**, 65–89 [1985]). With the availability of high-speed computers and the development of the field of computational fluid dynamics, numerical solutions accounting for two-dimensional flow aspects, along with gravitational, viscous, inertial, and surface tension forces are now the most effective means to analyze coating flow problems.

Other common coating flows include premetered flows, such as **slide** and **curtain coating**, where the film thickness is an independent parameter that may be controlled within limits, and the curvature of the meniscus adjusts accordingly; the closely related **blade coating**; and **roll coating** and **extrusion coating**. See Ruschak (ibid.), Cohen and Gutoff (*Modern Coating and Drying Technology*, VCH Publishers, New York, 1992), and Middleman (*Fundamentals of Polymer Processing*, McGraw-Hill, New York, 1977). For dip coating of wires, see Taughy (*Int. J. Numerical Meth. Fluids*, **4**, 441–475 [1984]).

Many coating flows are subject to instabilities that lead to unacceptable coating defects. Three-dimensional flow instabilities lead to such problems as **ribbing**. Air entrainment is another common defect.

**FALLING FILMS**

**Minimum Wetting Rate** The minimum liquid rate required for complete wetting of a vertical surface is about 0.03 to 0.3 kg/m · s for water at room temperature. The minimum rate depends on the geometry and nature of the vertical surface, liquid surface tension, and mass transfer between surrounding gas and the liquid. See Ponter, et al. (*Int. J. Heat Mass Transfer*, **10**, 349–359 [1967]; *Trans. Inst. Chem.*

FIG. 6-52 Falling film.

*Eng. [London]*, **45**, 345–352 [1967]), Stainthorp and Allen (*Trans. Inst. Chem. Eng. [London]*, **43**, 85–91 [1967]) and Watanabe, et al. (*J. Chem. Eng. [Japan]*, **8**[1], 75 [1975]).

**Laminar Flow** For films falling down **vertical flat surfaces**, as shown in Fig. 6-52, or vertical tubes with small film thickness compared to tube radius, laminar flow conditions prevail for Reynolds numbers less than about 2,000, where the Reynolds number is given by

$$Re = \frac{4\Gamma}{\mu} \quad (6-198)$$

where  $\Gamma$  = liquid mass flow rate per unit width of surface and  $\mu$  = liquid viscosity. For a flat film surface, the following equations may be derived. The film thickness  $\delta$  is

$$\delta = \left( \frac{3\Gamma\mu}{\rho^2 g} \right)^{1/3} \quad (6-199)$$

The average film velocity is

$$V = \frac{\Gamma}{\rho\delta} = \frac{g\rho\delta^2}{3\mu} \quad (6-200)$$

The downward velocity profile  $u(x)$  where  $x = 0$  at the solid surface and  $x = \delta$  at the liquid/gas interface is given by

$$u = 1.5V \left[ \frac{2x}{\delta} - \left( \frac{x}{\delta} \right)^2 \right] \quad (6-201)$$

These equations assume that there is no drag force at the gas/liquid interface, such as would be produced by gas flow. For a flat surface **inclined** at an angle  $\theta$  with the horizontal, the preceding equations may be modified by replacing  $g$  by  $g \sin \theta$ . For films falling inside vertical tubes with film thickness up to and including the full pipe radius, see Jackson (*AIChE J.*, **1**, 231–240 [1955]).

These equations have generally given good agreement with experimental results for low-viscosity liquids ( $< 0.005 \text{ Pa} \cdot \text{s}$ ) ( $< 5 \text{ cP}$ ) whereas Jackson (ibid.) found film thicknesses for higher-viscosity liquids (0.01 to 0.02 Pa·s (10 to 20 cP) were significantly less than predicted by Eq. (6-197). At Reynolds numbers of 25 or greater, **surface waves** will be present on the liquid film. West and Cole (*Chem. Eng. Sci.*, **22**, 1388–1389 [1967]) found that the surface velocity  $u(x = \delta)$  is still within  $\pm 7$  percent of that given by Eq. (6-201) even in wavy flow.

For laminar non-Newtonian film flow, see Bird, Armstrong, and Hassager (*Dynamics of Polymeric Liquids*, vol. 1: *Fluid Mechanics*, Wiley, New York, 1977, p. 215, 217), Astarita, Marrucci, and Palumbo (*Ind. Eng. Chem. Fundam.*, **3**, 333–339 [1964]) and Cheng (*Ind. Eng. Chem. Fundam.*, **13**, 394–395 [1974]).

**Turbulent Flow** In turbulent flow,  $Re > 2,000$ , for vertical surfaces, the film thickness may be estimated to within  $\pm 25$  percent using

$$\delta = 0.304 \left( \frac{\Gamma^{1.75} \mu^{0.25}}{\rho^2 g} \right)^{1/3} \quad (6-202)$$

Replace  $g$  by  $g \sin \theta$  for a surface inclined at angle  $\theta$  to the horizontal. The average film velocity is  $V = \Gamma/\rho\delta$ .

Tallmadge and Gutfinger (*Ind. Eng. Chem.*, **59**[11], 19–34 [1967]) discuss prediction of drainage rates from liquid films on flat and cylindrical surfaces.

**Effect of Surface Traction** If a drag is exerted on the surface of the film because of motion of the surrounding fluid, the film thickness will be reduced or increased, depending upon whether the drag acts with or against gravity. Thomas and Portalski (*Ind. Eng. Chem.*, **50**, 1081–1088 [1958]), Dukler (*Chem. Eng. Prog.*, **55**[10], 62–67 [1959]), and Kosky (*Int. J. Heat Mass Transfer*, **14**, 1220–1224 [1971]) have presented calculations of film thickness and film velocity. Film thickness data for falling water films with cocurrent and countercurrent air flow in pipes are given by Zhivaikin (*Int. Chem. Eng.*, **2**, 337–341 [1962]), Zabarás, Dukler, and Moalem-Maron (*AIChE J.*, **32**, 829–843 [1986]) and Zabarás and Dukler (*AIChE J.*, **34**, 389–396 [1988]) present studies of film flow in vertical tubes with both cocurrent and countercurrent gas flow, including measurements of film thickness, wall shear stress, wave velocity, wave amplitude, pressure drop, and flooding point for countercurrent flow.

**Flooding** With countercurrent gas flow, a condition is reached with increasing gas rate for which flow reversal occurs and liquid is carried upward. The mechanism for this flooding condition has been most often attributed to waves either bridging the pipe or reversing direction to flow upward at flooding. However, the results of Zabarás and Dukler (*ibid.*) suggest that flooding may be controlled by flow conditions at the liquid inlet and that wave bridging or upward wave motion does not occur, at least for the 50.8-mm diameter pipe used for their study. Flooding mechanisms are still incompletely understood. Under some circumstances, as when the gas is allowed to develop its normal velocity profile in a “calming length” of pipe beneath the liquid draw-off, the gas superficial velocity at flooding will be increased, and increases with decreasing length of wetted pipe (Hewitt, Lacy, and Nicholls, *Proc. Two-Phase Flow Symp.*, University of Exeter, paper 4H, AERE-4 4614 [1965]). A bevel cut at the bottom of the pipe with an angle  $30^\circ$  from the vertical will increase the flooding velocity in small-diameter tubes at moderate liquid flow rates. If the gas approaches the tube from the side, the taper should be oriented with the point facing the gas entrance. Figures 6-53 and 6-54 give correlations for flooding in tubes with square and slant bottoms (courtesy Holmes, DuPont Co.) The superficial mass velocities of gas and liquid  $G_G$  and  $G_L$ , and the physical property parameters  $\lambda$  and  $\psi$  are the same as those defined for the Baker chart (“Multiphase Flow” subsection, Fig. 6-25). For tubes larger than 50 mm (2 in), flooding velocity appears to be relatively insensitive to diameter and the flooding curves for 1.98-in diameter may be used.

**HYDRAULIC TRANSIENTS**

Many transient flows of liquids may be analyzed by using the full time-dependent equations of motion for incompressible flow. However,

**FIG. 6-53** Flooding in vertical tubes with square top and square bottom. To convert  $\text{lbm}/(\text{ft}^2 \cdot \text{s})$  to  $\text{kg}/(\text{m}^2 \cdot \text{s})$ , multiply by 4.8824; to convert in to mm, multiply by 25.4. (Courtesy of E. I. du Pont de Nemours & Co.)

**FIG. 6-54** Flooding in vertical tubes with square top and slant bottom. To convert  $\text{lbm}/(\text{ft}^2 \cdot \text{s})$  to  $\text{kg}/(\text{m}^2 \cdot \text{s})$ , multiply by 4.8824; to convert in to mm, multiply by 25.4. (Courtesy of E. I. du Pont de Nemours & Co.)

there are some phenomena that are controlled by the small compressibility of liquids. These phenomena are generally called **hydraulic transients**.

**Water Hammer** When liquid flowing in a pipe is suddenly decelerated to zero velocity by a fast-closing valve, a pressure wave propagates upstream to the pipe inlet, where it is reflected; a pounding of the line commonly known as **water hammer** is often produced. For an instantaneous flow stoppage of a truly incompressible fluid in an inelastic pipe, the pressure rise would be infinite. Finite compressibility of the fluid and elasticity of the pipe limit the pressure rise to a finite value. The Joukowski formula gives the maximum pressure rise as

$$\Delta p = \rho a \Delta V \tag{6-203}$$

where  $\rho$  = liquid density  
 $\Delta V$  = change in liquid velocity  
 $a$  = pressure wave velocity

The wave velocity is given by

$$a = \frac{\sqrt{\beta/\rho}}{\sqrt{1 + (\beta/E)(D/b)}} \tag{6-204}$$

where  $\beta$  = liquid bulk modulus of elasticity  
 $E$  = elastic modulus of pipe wall  
 $D$  = pipe inside diameter  
 $b$  = pipe wall thickness

The numerator gives the wave velocity for perfectly rigid pipe, and the denominator corrects for wall elasticity. This formula is for thin-walled pipes; for thick-walled pipes, the factor  $D/b$  is replaced by

$$2 \frac{D_o^3 + D_i^3}{D_o^3 - D_i^3}$$

where  $D_o$  = pipe outside diameter  
 $D_i$  = pipe inside diameter

**Example 10: Response to Instantaneous Valve Closing** Compute the wave speed and maximum pressure rise for instantaneous valve closing, with an initial velocity of 2.0 m/s, in a 4-in Schedule 40 steel pipe with elastic modulus  $207 \times 10^9$  Pa. Repeat for a plastic pipe of the same dimensions, with  $E = 1.4 \times 10^9$  Pa. The liquid is water with  $\beta = 2.2 \times 10^9$  Pa and  $\rho = 1,000 \text{ kg/m}^3$ . For the steel pipe,  $D = 102.3 \text{ mm}$ ,  $b = 6.02 \text{ mm}$ , and the wave speed is

$$\begin{aligned} a &= \frac{\sqrt{\beta/\rho}}{\sqrt{1 + (\beta/E)(D/b)}} \\ &= \frac{\sqrt{2.2 \times 10^9/1000}}{\sqrt{1 + (2.2 \times 10^9/207 \times 10^9)(102.3/6.02)}} \\ &= 1365 \text{ m/s} \end{aligned}$$

The maximum pressure rise is

$$\Delta p = \rho a \Delta V = 1,000 \times 1,365 \times 2.0 = 2.73 \times 10^6 \text{ Pa}$$

For the plastic pipe,

$$a = \frac{\sqrt{2.2 \times 10^9 / 1000}}{\sqrt{1 + (2.2 \times 10^9 / 1.4 \times 10^9)(102.3/6.02)}} = 282 \text{ m/s}$$

$$\Delta p = \rho a \Delta V = 1,000 \times 282 \times 2.0 = 5.64 \times 10^5 \text{ Pa}$$

The maximum pressure surge is obtained when the valve closes in less time than the period  $\tau$  required for the pressure wave to travel from the valve to the pipe inlet and back, a total distance of  $2L$ .

$$\tau = \frac{2L}{a} \tag{6-205}$$

The pressure surge will be reduced when the time of flow stoppage exceeds the pipe period  $\tau$ , due to cancellation between direct and reflected waves. Wood and Jones (*Proc. Am. Soc. Civ. Eng., J. Hydraul. Div.*, **99**, (HY1), 167–178 [1973]) present charts for reliable estimates of water-hammer pressure for different valve closure modes. Wylie and Streeter (*Hydraulic Transients*, McGraw-Hill, New York, 1978) describe several solution methods for hydraulic transients, including the method of characteristics, which is well suited to computer methods for accurate solutions. A rough approximation for the peak pressure for cases where the valve closure time  $t_c$  exceeds the pipe period  $\tau$  is (Daugherty and Franzini, *Fluid Mechanics with Engineering Applications*, McGraw-Hill, New York, 1985):

$$\Delta p \approx \left(\frac{\tau}{t_c}\right) \rho a \Delta V \tag{6-206}$$

Successive reflections of the pressure wave between the pipe inlet and the closed valve result in alternating pressure increases and decreases, which are gradually attenuated by fluid friction and imperfect elasticity of the pipe. Periods of reduced pressure occur while the reflected pressure wave is traveling from inlet to valve. Degassing of the liquid may occur, as may vaporization if the pressure drops below the vapor pressure of the liquid. Gas and vapor bubbles decrease the wave velocity. Vaporization may lead to what is often called *liquid column separation*; subsequent collapse of the vapor pocket can result in pipe rupture.

In addition to water hammer induced by changes in valve setting, including closure, numerous other hydraulic transient flows are of interest, as, for example (Wylie and Streeter, *Hydraulic Transients*, McGraw-Hill, New York, 1978), those arising from starting or stopping of pumps; changes in power demand from turbines; reciprocating pumps; changing elevation of a reservoir; waves on a reservoir; turbine governor hunting; vibration of impellers or guide vanes in pumps, fans, or turbines; vibration of deformable parts such as valves; draft-tube instabilities due to vortexing; and unstable pump or fan characteristics. Tube failure in heat exchangers may be added to this list.

**Pulsating Flow** Reciprocating machinery (pumps and compressors) produces flow pulsations, which adversely affect flow meters and process control elements and can cause vibration and equipment failure, in addition to undesirable process results. Vibration and damage can result not only from the fundamental frequency of the pulse producer but also from higher harmonics. Multipiston double-acting units reduce vibrations. Pulsation dampeners are often added. Damping methods are described by M. W. Kellogg Co. (*Design of Piping Systems*, rev. 2d ed., Wiley, New York, 1965). For liquid phase pulsation damping, gas-filled surge chambers, also known as accumulators, are commonly used; see Wylie and Streeter (*Hydraulic Transients*, McGraw-Hill, New York, 1978).

Software packages are commercially available for simulation of hydraulic transients. These may be used to analyze piping systems to reveal unsatisfactory behavior, and they allow the assessment of design changes such as increases in pipe-wall thickness, changes in valve actuation, and addition of check valves, surge tanks, and pulsation dampeners.

**Cavitation** Loosely regarded as related to water hammer and hydraulic transients because it may cause similar vibration and equipment damage, **cavitation** is the phenomenon of collapse of vapor bubbles in flowing liquid. These bubbles may be formed anywhere the local liquid pressure drops below the vapor pressure, or they may be injected into the liquid, as when steam is sparged into water. Local low-pressure zones may be produced by local velocity increases (in accordance with the Bernoulli equation; see the preceding “Conservation Equations” subsection) as in eddies or vortices, or near boundary contours; by rapid vibration of a boundary; by separation of liquid during water hammer; or by an overall reduction in static pressure, as due to pressure drop in the suction line of a pump.

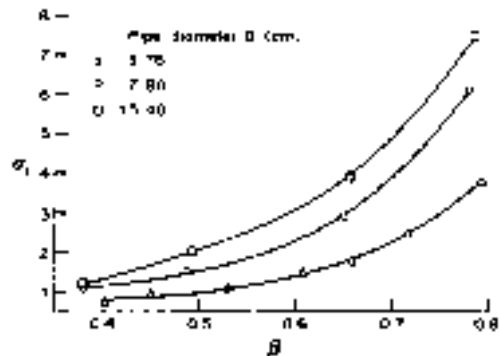

Collapse of vapor bubbles once they reach zones where the pressure exceeds the vapor pressure can cause objectionable noise and vibration and extensive erosion or pitting of the boundary materials. The critical cavitation number at inception of cavitation, denoted  $\sigma_c$ , is useful in correlating equipment performance data:

$$\sigma_c = \frac{p - p_v}{\rho V^2 / 2} \tag{6-207}$$

where  $p$  = static pressure in undisturbed flow  
 $p_v$  = vapor pressure  
 $\rho$  = liquid density  
 $V$  = free-stream velocity of the liquid

The value of the cavitation number for incipient cavitation for a specific piece of equipment is a characteristic of that equipment. Cavitation numbers for various head forms of cylinders, for disks, and for various hydrofoils are given by Holl and Wislicenus (*J. Basic Eng.*, **83**, 385–398 [1961]) and for various surface irregularities by Arndt and Ippen (*J. Basic Eng.*, **90**, 249–261 [1968]), Ball (*Proc. ASCE J. Constr. Div.*, **89**(C02), 91–110 [1963]), and Holl (*J. Basic Eng.*, **82**, 169–183 [1960]). As a guide only, for blunt forms the cavitation number is generally in the range of 1 to 2.5, and for somewhat streamlined forms the cavitation number is in the range of 0.2 to 0.5. Critical cavitation numbers generally depend on a characteristic length dimension of the equipment in a way that has not been explained. This renders scale-up of cavitation data questionable.

For cavitation in flow through orifices, Fig. 6-55 (Thorpe, *Int. J. Multiphase Flow*, **16**, 1023–1045 [1990]) gives the critical cavitation number for inception of cavitation. To use this cavitation number in Eq. (6-207), the pressure  $p$  is the orifice backpressure downstream of the vena contracta after full pressure recovery, and  $V$  is the average velocity through the orifice. Figure 6-55 includes data from Tullis and Govindarajan (*ASCE J. Hydraul. Div.*, **HY13**, 417–430 [1973]) modified to use the same cavitation number definition; their data also include critical cavitation numbers for 30.50- and 59.70-cm pipes

**FIG. 6-55** Critical cavitation number vs. diameter ratio  $\beta$ . (Reprinted from Thorpe, “Flow regime transitions due to cavitation in the flow through an orifice,” *Int. J. Multiphase Flow*, **16**, 1023–1045. Copyright © 1990, with kind permission from Elsevier Science, Ltd., The Boulevard, Langford Lane, Kidlington OX5 1GB, United Kingdom.)

(12.00- to 23.50-in). Very roughly, compared with the 15.40-cm pipe, the cavitation number is about 20 percent greater for the 30.50-cm (12.01-in) pipe and about 40 percent greater for the 59.70-cm (23.50-in) diameter pipe. Inception of cavitation appears to be related to release of dissolved gas and not merely vaporization of the liquid. For further discussion of cavitation, see Eisenberg and Tulin (Streeter, *Handbook of Fluid Dynamics*, Sec. 12, McGraw-Hill, New York, 1961).

**TURBULENCE**

Turbulent flow occurs when the Reynolds number exceeds a critical value above which laminar flow is unstable; the critical Reynolds number depends on the flow geometry. There is generally a transition regime between the critical Reynolds number and the Reynolds number at which the flow may be considered fully turbulent. The transition regime is very wide for some geometries. In turbulent flow, variables such as velocity and pressure fluctuate chaotically; statistical methods are used to quantify turbulence.

**Time Averaging** In turbulent flows it is useful to define time-averaged and fluctuation values of flow variables such as velocity components. For example, the *x*-component velocity fluctuation  $v'_x$  is the difference between the actual instantaneous velocity  $v_x$  and the time-averaged velocity  $\bar{v}_x$ :

$$v'_x(x, y, z, t) = v_x(x, y, z, t) - \bar{v}_x(x, y, z) \tag{6-208}$$

The actual and fluctuating velocity components are, in general, functions of the three spatial coordinates *x*, *y*, and *z* and of time *t*. The time-averaged velocity  $\bar{v}_x$  is independent of time for a **stationary** flow. Nonstationary processes may be considered where averages are defined over time scales long compared to the time scale of the turbulent fluctuations, but short compared to longer time scales over which the time-averaged flow variables change due, for example, to time-varying boundary conditions. The time average over a time interval  $2T$  centered at time *t* of a turbulently fluctuating variable  $\zeta(t)$  is defined as

$$\bar{\zeta}(t) = \frac{1}{2T} \int_{t-T}^{t+T} \zeta(\tau) d\tau \tag{6-209}$$

where  $\tau$  = dummy integration variable. For stationary turbulence,  $\bar{\zeta}$  does not vary with time.

$$\bar{\zeta} = \lim_{T \rightarrow \infty} \frac{1}{2T} \int_{t-T}^{t+T} \zeta(\tau) d\tau \tag{6-210}$$

The time average of a fluctuation  $\bar{\zeta}' = \bar{\zeta} - \bar{\zeta} = 0$ . Fluctuation magnitudes are quantified by root mean squares.

$$\bar{v}'_x = \sqrt{\overline{(v'_x)^2}} \tag{6-211}$$

In **isotropic** turbulence, statistical measures of fluctuations are equal in all directions.

$$\bar{v}'_x = \bar{v}'_y = \bar{v}'_z \tag{6-212}$$

In **homogeneous** turbulence, turbulence properties are independent of spatial position. The **kinetic energy of turbulence** *k* is given by

$$k = \frac{1}{2} (\bar{v}'_x{}^2 + \bar{v}'_y{}^2 + \bar{v}'_z{}^2) \tag{6-213}$$

Turbulent velocity fluctuations ultimately dissipate their kinetic energy through viscous effects. Macroscopically, this energy dissipation requires pressure drop, or velocity decrease. The **energy dissipation rate** per unit mass is usually denoted  $\epsilon$ . For steady flow in a pipe, the average energy dissipation rate per unit mass is given by

$$\epsilon = \frac{2fV^3}{D} \tag{6-214}$$

where  $\rho$  = fluid density  
*f* = Fanning friction factor  
*D* = pipe inside diameter

When the continuity equation and the Navier-Stokes equations for incompressible flow are time averaged, equations for the time-averaged

velocities and pressures are obtained which appear identical to the original equations (6-18 through 6-28), except for the appearance of additional terms in the Navier-Stokes equations. Called **Reynolds stress** terms, they result from the nonlinear effects of momentum transport by the velocity fluctuations. In each *i*-component (*i* = *x*, *y*, *z*) Navier-Stokes equation, the following additional terms appear on the right-hand side:

$$\sum_{j=1}^3 \frac{\partial \tau'_{ij}}{\partial x_j}$$

with *j* components also being *x*, *y*, *z*. The Reynolds stresses are given by

$$\tau'_{ij} = -\rho \overline{v'_i v'_j} \tag{6-215}$$

The Reynolds stresses are nonzero because the velocity fluctuations in different coordinate directions are correlated so that  $\overline{v'_i v'_j}$  in general is nonzero.

Although direct numerical simulations under limited circumstances have been carried out to determine (unaveraged) fluctuating velocity fields, in general the solution of the equations of motion for turbulent flow is based on the time-averaged equations. This requires semi-empirical models to express the Reynolds stresses in terms of time-averaged velocities. This is the **closure** problem of turbulence. In all but the simplest geometries, numerical methods are required.

**Closure Models** Many closure models have been proposed. A few of the more important ones are introduced here. Many employ the Boussinesq approximation, simplified here for incompressible flow, which treats the Reynolds stresses as analogous to viscous stresses, introducing a scalar quantity called the turbulent or eddy viscosity  $\mu_t$ .

$$-\rho \overline{v'_i v'_j} = \mu_t \left( \frac{\partial \bar{v}_i}{\partial x_j} + \frac{\partial \bar{v}_j}{\partial x_i} \right) \tag{6-216}$$

An additional *turbulence pressure* term equal to  $-\frac{2}{3}k\delta_{ij}$ , where *k* = turbulent kinetic energy and  $\delta_{ij} = 1$  if *i* = *j* and  $\delta_{ij} = 0$  if *i* ≠ *j*, is sometimes included in the right-hand side. To solve the equations of motion using the Boussinesq approximation, it is necessary to provide equations for the single scalar unknown  $\mu_t$  (and *k*, if used) rather than the nine unknown tensor components  $\tau'_{ij}$ . With this approximation, and using the effective viscosity  $\mu_{\text{eff}} = \mu + \mu_t$ , the time-averaged momentum equation is similar to the original Navier-Stokes equation, with time-averaged variables and  $\mu_{\text{eff}}$  replacing the instantaneous variables and molecular viscosity. However, solutions to the time-averaged equations for turbulent flow are not identical to those for laminar flow because  $\mu_{\text{eff}}$  is not a constant.

The universal turbulent velocity profile near the pipe wall presented in the preceding subsection "Incompressible Flow in Pipes and Channels" may be developed using the Prandtl mixing length approximation for the eddy viscosity,

$$\mu_t = \rho l_p^2 \left| \frac{d\bar{v}_x}{dy} \right| \tag{6-217}$$

where *l<sub>p</sub>* is the Prandtl mixing length. The turbulent core of the universal velocity profile is obtained by assuming that the mixing length is proportional to the distance from the wall. The proportionality constant is one of two constants adjusted to fit experimental data.

The Prandtl mixing length concept is useful for shear flows parallel to walls, but is inadequate for more general three-dimensional flows. A more complicated semiempirical model commonly used in numerical computations, and found in most commercial software for computational fluid dynamics (CFD; see the following subsection), is the *k*- $\epsilon$  model described by Launder and Spaulding (*Lectures in Mathematical Models of Turbulence*, Academic, London, 1972). In this model the eddy viscosity is assumed proportional to the ratio  $k^2/\epsilon$ .

$$\mu_t = \rho C_\mu \frac{k^2}{\epsilon} \tag{6-218}$$

where the value  $C_\mu = 0.09$  is normally used. Semiempirical partial differential conservation equations for *k* and  $\epsilon$  derived from the

Navier-Stokes equations with simplifying closure assumptions are coupled with the equations of continuity and momentum:

$$\frac{\partial}{\partial t} (\rho k) + \frac{\partial}{\partial x_i} (\rho \bar{v}_i k) = \frac{\partial}{\partial x_i} \left( \frac{\mu_t}{\sigma_k} \frac{\partial k}{\partial x_i} \right) + \mu_t \left( \frac{\partial \bar{v}_i}{\partial x_j} + \frac{\partial \bar{v}_j}{\partial x_i} \right) \frac{\partial \bar{v}_i}{\partial x_j} - \rho \epsilon \quad (6-219)$$

$$\frac{\partial}{\partial t} (\rho \epsilon) + \frac{\partial}{\partial x_i} (\rho \bar{v}_i \epsilon) = \frac{\partial}{\partial x_i} \left( \frac{\mu_t}{\sigma_\epsilon} \frac{\partial \epsilon}{\partial x_i} \right) + C_{1\epsilon} \frac{\epsilon \mu_t}{k} \left( \frac{\partial \bar{v}_i}{\partial x_j} + \frac{\partial \bar{v}_j}{\partial x_i} \right) \frac{\partial \bar{v}_i}{\partial x_j} - C_{2\epsilon} \frac{\rho \epsilon^2}{k} \quad (6-220)$$

In these equations summations over repeated indices are implied. The values for the empirical constants  $C_{1\epsilon} = 1.44$ ,  $C_{2\epsilon} = 1.92$ ,  $\sigma_k = 1.0$ , and  $\sigma_\epsilon = 1.3$  are widely accepted (Lauder and Spaulding, *The Numerical Computation of Turbulent Flows*, Imperial Coll. Sci. Tech. London, NTIS N74-12066 [1973]). The  $k-\epsilon$  model has proved reasonably accurate for many flows without highly curved streamlines or significant swirl. It usually underestimates flow separation and overestimates turbulence production by normal straining. The  $k-\epsilon$  model is suitable for high Reynolds number flows. See Virendra, Patel, Rodi, and Scheuerer (*AIAA J.*, **23**, 1308–1319 [1984]) for a review of low Reynolds number  $k-\epsilon$  models.

More advanced models, more complex and computationally intensive, are being developed. For example, the renormalization group theory (Yakhot and Orszag, *J. Scientific Computing*, **1**, 1–51 [1986]; Yakhot, Orszag, Thangam, Gatski, and Speziale, *Phys. Fluids A*, **4**, 1510–1520 [1992]) modification of the  $k-\epsilon$  model provides theoretical values of the model constants and provides substantial improvement in predictions of flows with stagnation, separation, normal straining, transient behavior such as vortex shedding, and relaminarization. Stress transport models provide equations for all nine Reynolds stress components, rather than introducing eddy viscosity. Algebraic closure equations for the Reynolds stresses are available, but are no longer in common use. Differential Reynolds stress models (e.g., Launder, Reece, and Rodi, *J. Fluid Mech.*, **68**, 537–566 [1975]) use differential conservation equations for all nine Reynolds stress components.

In **direct numerical simulation** of turbulent flows, the solution of the unaveraged equations of motion is sought. Due to the extreme computational intensity, solutions to date have been limited to relatively low Reynolds numbers in simple geometries. Since computational grids must be sufficiently fine to resolve even the smallest eddies, the computational difficulty rapidly becomes prohibitive as Reynolds number increases. **Large eddy simulations** use models for subgrid turbulence while solving for larger-scale fluctuations.

**Eddy Spectrum** The energy that produces and sustains turbulence is extracted from velocity gradients in the mean flow, principally through vortex stretching. At Reynolds numbers well above the critical value there is a wide spectrum of eddy sizes, often described as a cascade of energy from the largest down to the smallest eddies. The largest eddies are of the order of the equipment size. The smallest are those for which viscous forces associated with the eddy velocity fluctuations are of the same order as inertial forces, so that turbulent fluctuations are rapidly damped out by viscous effects at smaller length scales. Most of the turbulent kinetic energy is contained in the larger eddies, while most of the dissipation occurs in the smaller eddies. Large eddies, which extract energy from the mean flow velocity gradients, are generally anisotropic. At smaller length scales, the directionality of the mean flow exerts less influence, and **local isotropy** is approached. The range of eddy scales for which local isotropy holds is called the **equilibrium range**.

Davies (*Turbulence Phenomena*, Academic, New York, 1972) presents a good discussion of the spectrum of eddy lengths for well-developed isotropic turbulence. The smallest eddies, usually called *Kolmogorov eddies* (Kolmogorov, *Compt. Rend. Acad. Sci. URSS*, **30**, 301; **32**, 16 [1941]), have a characteristic velocity fluctuation  $\bar{v}'_k$  given by

$$\bar{v}'_k = (\nu \epsilon)^{1/4} \quad (6-221)$$

where  $\nu$  = kinematic viscosity and  $\epsilon$  = energy dissipation per unit mass. The size of the Kolmogorov eddy scale is

$$l_K = (\nu^3/\epsilon)^{1/4} \quad (6-222)$$

The Reynolds number for the Kolmogorov eddy,  $Re_K = l_K \bar{v}'_k/\nu$ , is equal to unity by definition. In the equilibrium range, which exists for well-developed turbulence and extends from the medium eddy sizes down to the smallest, the energy dissipation at the smaller length scales is supplied by turbulent energy drawn from the bulk flow and passed down the spectrum of eddy lengths according to the scaling rule

$$\epsilon = \frac{(\bar{v}')^3}{l} \quad (6-223)$$

which is consistent with Eqs. (6-221) and (6-222). For the medium, or energy-containing, eddy size,

$$\epsilon = \frac{(\bar{v}'_e)^3}{l_e} \quad (6-224)$$

For turbulent pipe flow, the friction velocity  $u_* = \sqrt{\tau_w/\rho}$  used earlier in describing the universal turbulent velocity profile may be used as an estimate for  $\bar{v}'_e$ . Together with the Blasius equation for the friction factor from which  $\epsilon$  may be obtained (Eq. 6-214), this provides an estimate for the energy-containing eddy size in turbulent pipe flow:

$$l_e = 0.05 D Re^{-1/8} \quad (6-225)$$

where  $D$  = pipe diameter and  $Re$  = pipe Reynolds number. Similarly, the Kolmogorov eddy size is

$$l_K = 4 D Re^{-0.78} \quad (6-226)$$

Most of the energy dissipation occurs on a length scale about 5 times the Kolmogorov eddy size. The characteristic fluctuating velocity for these energy-dissipating eddies is about 1.7 times the Kolmogorov velocity.

The eddy spectrum is normally described using Fourier transform methods; see, for example, Hinze (*Turbulence*, McGraw-Hill, New York, 1975), and Tennekes and Lumley (*A First Course in Turbulence*, MIT Press, Cambridge, 1972). The spectrum  $E(\kappa)$  gives the fraction of turbulent kinetic energy contained in eddies of wavenumber between  $\kappa$  and  $\kappa + d\kappa$ , so that  $k = \int_0^\infty E(\kappa) d\kappa$ . The portion of the equilibrium range excluding the smallest eddies, those which are affected by dissipation, is the **inertial subrange**. The Kolmogorov law gives  $E(\kappa) \propto \kappa^{-5/3}$  in the inertial subrange.

Several texts are available for further reading on turbulent flow, including Pope (*Turbulent Flows*, Cambridge University Press, Cambridge, U.K., 2000), Tennekes and Lumley (*ibid.*), Hinze (*Turbulence*, McGraw-Hill, New York, 1975), Landau and Lifshitz (*Fluid Mechanics*, 2d ed., Chap. 3, Pergamon, Oxford, 1987) and Panton (*Incompressible Flow*, Wiley, New York, 1984).

## COMPUTATIONAL FLUID DYNAMICS

Computational fluid dynamics (CFD) emerged in the 1980s as a significant tool for fluid dynamics both in research and in practice, enabled by rapid development in computer hardware and software. Commercial CFD software is widely available. Computational fluid dynamics is the numerical solution of the equations of continuity and momentum (Navier-Stokes equations for incompressible Newtonian fluids) along with additional conservation equations for energy and material species in order to solve problems of nonisothermal flow, mixing, and chemical reaction.

Textbooks include Fletcher (*Computational Techniques for Fluid Dynamics*, vol. 1: *Fundamental and General Techniques*, and vol. 2: *Specific Techniques for Different Flow Categories*, Springer-Verlag, Berlin, 1988), Hirsch (*Numerical Computation of Internal and External Flows*, vol. 1: *Fundamentals of Numerical Discretization*, and vol. 2: *Computational Methods for Inviscid and Viscous Flows*, Wiley, New York, 1988), Peyret and Taylor (*Computational Methods for Fluid*

**FIG. 6-56** Computational fluid dynamic simulation of flow over a square cylinder, showing one vortex shedding period. (From Choudhury *et al.*, Trans. ASME Fluids Div., TN-076 [1994].)

Flow, Springer-Verlag, Berlin, 1990), Canuto, Hussaini, Quarteroni, and Zang (*Spectral Methods in Fluid Dynamics*, Springer-Verlag, Berlin, 1988), Anderson, Tannehill, and Pletcher (*Computational Fluid Mechanics and Heat Transfer*, Hemisphere, New York, 1984), and Patankar (*Numerical Heat Transfer and Fluid Flow*, Hemisphere, Washington, D.C., 1980).

A wide variety of numerical methods has been employed, but three basic steps are common.

1. **Subdivision or discretization of the flow domain into cells or elements.** There are methods, called *boundary element methods*, in which the surface of the flow domain, rather than the volume, is discretized, but the vast majority of CFD work uses volume discretization. Discretization produces a set of **grid** lines or curves which define a **mesh** and a set of **nodes** at which the flow variables are to be calculated. The equations of motion are solved approximately on a domain defined by the grid. Curvilinear or **body-fitted** coordinate system grids may be used to ensure that the discretized domain accurately represents the true problem domain.

2. **Discretization of the governing equations.** In this step, the exact partial differential equations to be solved are replaced by approximate algebraic equations written in terms of the nodal values of the dependent variables. Among the numerous discretization methods, **finite difference**, **finite volume**, and **finite element** methods are the most common. The *finite difference* method estimates spatial derivatives in terms of the nodal values and spacing between nodes. The governing equations are then written in terms of the nodal unknowns at each interior node. *Finite volume* methods, related to finite difference methods, may be derived by volume integration of the equations of motion, with application of the divergence theorem, reducing by one the order of the differential equations. Equivalently, macroscopic balance equations are written on each cell. *Finite element* methods are weighted residual techniques in which the unknown dependent variables are expressed in terms of **basis functions** interpolating among the nodal values. The basis functions are substituted into the equations of motion, resulting in error residuals which are multiplied by the weighting functions, integrated over the control volume, and set to zero to produce algebraic equations in terms of the nodal unknowns. Selection of the weighting functions defines the various finite element methods. For example, Galerkin's method uses the nodal interpolation basis functions as weighting functions. Each method also has its own method for implementing **boundary conditions**. The end result after discretization of the equations and application of the boundary conditions is a set of algebraic equations for the nodal unknown variables. Discretization in time is also required for the  $\partial/\partial t$  time derivative terms in unsteady flow; finite differencing in time is often used. The discretized equations represent an approximation of the exact equations, and their solution gives an approximation for the flow variables. The accuracy of the solution improves as the grid is **refined**; that is, as the number of nodal points is increased.

3. **Solution of the algebraic equations.** For creeping flows with constant viscosity, the algebraic equations are linear and a linear matrix equation is to be solved. Both direct and iterative solvers have been used. For most flows, the nonlinear inertial terms in the momentum equation are important and the algebraic discretized equations are therefore nonlinear. Solution yields the nodal values of the unknowns.

A CFD method called the lattice Boltzmann method is based on modeling the fluid as a set of particles moving with discrete velocities on a discrete grid or lattice, rather than on discretization of the governing continuum partial differential equations. Lattice Boltzmann approximations can be constructed that give the same macroscopic behavior as the Navier-Stokes equations. The method is currently used mainly in academic and research codes, rather than in general-purpose commercial CFD codes. There appear to be significant computational advantages to the lattice Boltzmann method. Lattice Boltzmann simulations incorporating turbulence models, and of multiphase flows and flows with heat transfer, species diffusion, and reaction, have been carried out. For a review of the method, see Chen and Doolen [*Ann. Rev. Fluid Mech.*, **30**, 329 (1998)].

CFD solutions, especially for complex three-dimensional flows, generate very large quantities of solution data. Computer graphics have greatly improved the ability to examine CFD solutions and visualize flow.

CFD methods are used for incompressible and compressible, creeping, laminar and turbulent, Newtonian and non-Newtonian, and isothermal and nonisothermal flows. Chemically reacting flows, particularly in the field of combustion, have been simulated. Solution accuracy must be considered from several perspectives. These include convergence of the algorithms for solving the nonlinear discretized equations and convergence with respect to refinement of the mesh so that the discretized equations better approximate the exact equations and, in some cases, so that the mesh more accurately fits the true geometry. The possibility that steady-state solutions are unstable must always be considered. In addition to numerical sources of error, modeling errors are introduced in turbulent flow, where semiempirical closure models are used to solve time-averaged equations of motion, as discussed previously. Most commercial CFD codes include the  $k-\epsilon$  turbulence model, which has been by far the most widely used. More accurate models, such as differential Reynolds stress and renormalization group theory models, are also becoming available. Significant solution error is known to result in some problems from inadequacy of the turbulence model. Closure models for nonlinear chemical reaction source terms may also contribute to inaccuracy.

Large eddy simulation (LES) methods for turbulent flow are available in some commercial CFD codes. LES methods are based on filtering fluctuating variables, so that lower-frequency eddies, with scales larger than the grid spacing, are resolved, while higher-frequency eddies, the subgrid fluctuations, are filtered out. The subgrid-scale Reynolds stress is estimated by a turbulence model. The Smagorinsky model, a one-equation mixing length model, is used in most commercial codes that offer LES options and is also used in many academic and research CFD codes. See Wilcox (*Turbulence Modeling for CFD*, 2d ed., DCW Industries, La Cañada, Calif., 1998).

In its general sense, multiphase flow is not currently solvable by computational fluid dynamics. However, in certain cases reasonable solutions are possible. These include well-separated flows where the phases are confined to relatively well-defined regions separated by one or a few interfaces and flows in which a second phase appears as discrete particles of known size and shape whose motion may be approximately computed with drag coefficient formulations, or rigorously computed with refined meshes applying boundary conditions at the particle surface. **Two-fluid modeling**, in which the phases are treated as overlapping continua, with each phase occupying a volume fraction that is a continuous function of position (and time) is a useful approximation which is becoming available in commercial software. See Elghobashi and Abou-Arab (*J. Physics Fluids*, **26**, 931-938 [1983]) for a  $k-\epsilon$  model for two-fluid systems.

Figure 6-56 gives an example CFD calculation for time-dependent flow past a square cylinder at a Reynolds number of 22,000 (Choudhury, et al., *Trans. ASME Fluids Div.*, Lake Tahoe, Nev. [1994]). The computation was done with an implementation of the renormalization group theory  $k-\epsilon$  model. The series of contour plots of stream function shows a sequence in time over about 1 vortex-shedding period. The calculated Strouhal number (Eq. [6-195]) is 0.146, in excellent agreement with experiment, as is the time-averaged drag coefficient,  $C_D = 2.24$ . Similar computations for a circular cylinder at  $Re = 14,500$  have given excellent agreement with experimental measurements for  $St$  and  $C_D$  (*Introduction to the Renormalization Group Method and Turbulence Modeling*, Fluent, Inc., 1993).

## DIMENSIONLESS GROUPS

For purposes of data correlation, model studies, and scale-up, it is useful to arrange variables into dimensionless groups. Table 6-7 lists many of the dimensionless groups commonly found in fluid mechanics problems, along with their physical interpretations and areas of application. More extensive tabulations may be found in Catchpole and Fulford (*Ind. Eng. Chem.*, **58**[3], 46-60 [1966]) and Fulford and Catchpole (*Ind. Eng. Chem.*, **60**[3], 71-78 [1968]).

## 6-50 FLUID AND PARTICLE DYNAMICS

**TABLE 6-7 Dimensionless Groups and Their Significance**

| Name                      | Symbol          | Formula  | Physical interpretation  | Comments   |
|---------------------------|-----------------|--|--|--|
| Archimedes number         | Ar              | $\frac{gL^3(\rho_p - \rho)\rho}{\mu^3}$                    | $\frac{\text{inertial forces} \times \text{buoyancy forces}}{(\text{viscous forces})^2}$         | Particle settling  |
| Bingham number            | Bm              | $\frac{\tau_y L}{\mu_\infty V}$                            | $\frac{\text{yield stress}}{\text{viscous stress}}$  | Flow of Bingham plastics = yield number, Y                         |
| Bingham Reynolds number   | Re <sub>B</sub> | $\frac{LV\rho}{\mu_\infty}$                                | $\frac{\text{inertial force}}{\text{viscous force}}$   | Flow of Bingham plastics   |
| Blake number              | B               | $\frac{V\rho}{\mu(1 - \epsilon)^s}$                        | $\frac{\text{inertial force}}{\text{viscous force}}$   | Beds of solids   |
| Bond number               | Bo              | $\frac{(\rho_L - \rho_G)L^2g}{\sigma}$                     | $\frac{\text{gravitational force}}{\text{surface-tension force}}$                                | Atomization = Eotvos number, Eo                                    |
| Capillary number          | Ca              | $\frac{\mu V}{\sigma}$                                     | $\frac{\text{viscous force}}{\text{surface-tension force}}$                                      | Two-phase flows, free surface flows                                |
| Cauchy number             | C               | $\frac{\rho V^2}{\beta}$                                   | $\frac{\text{inertial force}}{\text{compressibility force}}$                                     | Compressible flow, hydraulic transients                            |
| Cavitation number         | $\sigma$        | $\frac{p - p_v}{\rho V^2/2}$                               | $\frac{\text{excess pressure above vapor pressure}}{\text{velocity head}}$                       | Cavitation   |
| Dean number               | D <sub>e</sub>  | $\frac{Re}{(Dc/D)^{1/2}}$                                  | Reynolds number $\times$ $\frac{\text{inertial force}}{\text{centrifugal force}}$                | Flow in curved channels  |
| Deborah number            | De              | $\lambda\omega$  | $\frac{\text{fluid relaxation time}}{\text{flow characteristic time}}$                           | Viscoelastic flow  |
| Drag coefficient          | C <sub>D</sub>  | $\frac{F_D}{ApV^2/2}$                                      | $\frac{\text{drag force}}{\text{projected area} \times \text{velocity head}}$                    | Flow around objects, particle settling                             |
| Elasticity number         | El              | $\frac{\lambda\mu}{\rho L^2}$                              | $\frac{\text{elastic force}}{\text{inertial force}}$   | Viscoelastic flow  |
| Euler number              | Eu              | $\frac{\Delta p}{\rho V^2}$                                | $\frac{\text{frictional pressure loss}}{2 \times \text{velocity head}}$                          | Fluid friction in conduits   |
| Fanning friction factor   | f               | $\frac{D\Delta p}{2\rho V^2 L} = \frac{2\tau_w}{\rho V^2}$ | $\frac{\text{wall shear stress}}{\text{velocity head}}$  | Fluid friction in conduits Darcy friction factor = 4f              |
| Froude number             | Fr              | $\frac{V^2}{gL}$   | $\frac{\text{inertial force}}{\text{gravity force}}$   | Often defined as Fr = V/√gL  |
| Densometric Froude number | Fr'             | $\frac{\rho V^2}{(\rho_d - \rho)gL}$                       | $\frac{\text{inertial force}}{\text{gravity force}}$   | or Fr' = $\frac{V}{\sqrt{(\rho_d - \rho)gL/\rho}}$                 |
| Hedstrom number           | He              | $\frac{L^2\tau_y\rho}{\mu_\infty^2}$                       | Bingham Reynolds number $\times$ Bingham number  | Flow of Bingham plastics   |

### DRAG COEFFICIENT

Whenever relative motion exists between a particle and a surrounding fluid, the fluid will exert a drag upon the particle. In steady flow, the drag force on the particle is

$$F_D = \frac{C_D A_P \rho u^2}{2} \quad (6-227)$$

- where  $F_D$  = drag force
- $C_D$  = drag coefficient
- $A_P$  = projected particle area in direction of motion
- $\rho$  = density of surrounding fluid
- $u$  = relative velocity between particle and fluid

The drag force is exerted in a direction parallel to the fluid velocity. Equation (6-227) defines the **drag coefficient**. For some solid bodies, such as aerofoils, a lift force component perpendicular to the liquid velocity is also exerted. For free-falling particles, lift

forces are generally not important. However, even spherical particles experience lift forces in shear flows near solid surfaces.

### TERMINAL SETTLING VELOCITY

A particle falling under the action of gravity will accelerate until the drag force balances gravitational force, after which it falls at a constant **terminal or free-settling velocity**  $u_t$ , given by

$$u_t = \sqrt{\frac{2gm_p(\rho_p - \rho)}{\rho\rho_p A_P C_D}} \quad (6-228)$$

- where  $g$  = acceleration of gravity
- $m_p$  = particle mass
- $\rho_p$  = particle density

and the remaining symbols are as previously defined.

Settling particles may undergo fluctuating motions owing to vortex shedding, among other factors. Oscillation is enhanced with increasing separation between the mass and geometric centers of the particle. Variations in mean velocity are usually less than 10 percent. The drag force on a particle fixed in space with fluid moving is somewhat lower than the drag force on a particle freely settling in a stationary fluid at the same relative velocity.

**Spherical Particles** For spherical particles of diameter  $d_p$ , Eq. (6-228) becomes

$$u_t = \sqrt{\frac{4gd_p(\rho_p - \rho)}{3\rho C_D}} \quad (6-229)$$

**FIG. 6-57** Drag coefficients for spheres, disks, and cylinders;  $A_p$  = area of particle projected on a plane normal to direction of motion;  $C$  = overall drag coefficient, dimensionless;  $D_p$  = diameter of particle;  $F_d$  = drag or resistance to motion of body in fluid;  $Re$  = Reynolds number, dimensionless;  $u$  = relative velocity between particle and main body of fluid;  $\mu$  = fluid viscosity; and  $\rho$  = fluid density. (From Lapple and Shepherd, *Ind. Eng. Chem.*, **32**, 605 [1940].)

The drag coefficient for rigid spherical particles is a function of particle Reynolds number,  $Re_p = d_p \rho u / \mu$  where  $\mu$  = fluid viscosity, as shown in Fig. 6-57. At low Reynolds number, **Stokes' law** gives

$$C_D = \frac{24}{Re_p} \quad Re_p < 0.1 \quad (6-230)$$

which may also be written

$$F_D = 3\pi\mu u d_p \quad Re_p < 0.1 \quad (6-231)$$

and gives for the terminal settling velocity

$$u_t = \frac{g d_p^2 (\rho_p - \rho)}{18\mu} \quad Re_p < 0.1 \quad (6-232)$$

In the **intermediate regime** ( $0.1 < Re_p < 1,000$ ), the drag coefficient may be estimated within 6 percent by

$$C_D = \left( \frac{24}{Re_p} \right) \left( 1 + 0.14 Re_p^{0.70} \right) \quad 0.1 < Re_p < 1,000 \quad (6-233)$$

In the **Newton's law regime**, which covers the range  $1,000 < Re_p < 350,000$ ,  $C_D = 0.445$ , within 13 percent. In this region, Eq. (6-227) becomes

$$u_t = 1.73 \sqrt{\frac{g d_p (\rho_p - \rho)}{\rho}} \quad 1,000 < Re_p < 350,000 \quad (6-234)$$

Between about  $Re_p = 350,000$  and  $1 \times 10^6$ , the drag coefficient drops dramatically in a **drag crisis** owing to the transition to turbulent flow in the boundary layer around the particle, which delays aft separation, resulting in a smaller wake and less drag. Beyond  $Re = 1 \times 10^6$ , the drag coefficient may be estimated from (Clift, Grace, and Weber):

$$C_D = 0.19 - \frac{8 \times 10^4}{Re_p} \quad Re_p > 1 \times 10^6 \quad (6-235)$$

Drag coefficients may be affected by turbulence in the free-stream flow; the drag crisis occurs at lower Reynolds numbers when the free

stream is turbulent. Torobin and Guvin (*AIChE J.*, **7**, 615–619 [1961]) found that the drag crisis Reynolds number decreases with increasing free-stream turbulence, reaching a value of 400 when the relative turbulence intensity, defined as  $\sqrt{u'}/U_R$  is 0.4. Here  $\sqrt{u'}$  is the rms fluctuating velocity and  $U_R$  is the relative velocity between the particle and the fluid.

For computing the terminal settling velocity, correlations for drag coefficient as a function of Archimedes number

$$Ar = \frac{g d_p^3 (\rho_p - \rho)}{\mu^2} \quad (6-236)$$

may be more convenient than  $C_D$ - $Re$  correlations, because the latter are implicit in terminal velocity, and the settling regime is unknown. Karamanev [*Chem. Eng. Comm.* **147**, 75 (1996)] provided a correlation for drag coefficient for settling solid spheres in terms of  $Ar$ .

$$C_D = \frac{432}{Ar} (1 + 0.0470 Ar^{0.23}) + \frac{0.517}{1 + 154 Ar^{-1/3}} \quad (6-237)$$

This equation reduces to Stokes' law  $C_D = 24/Re$  in the limit  $Ar \rightarrow 0$  and is a fit to data up to about  $Ar = 2 \times 10^{10}$ , where it gives  $C_D = 0.50$ , slightly greater than the Newton's law value above. For rising light spheres, which exhibit more energy dissipating lateral motion than do falling dense spheres, Karamanev found that Eq. (6-237) is followed up to  $Ar = 13,000$  and that for  $Ar > 13,000$ , the drag coefficient is  $C_D = 0.95$ .

For particles settling in **non-Newtonian** fluids, correlations are given by Dallon and Christiansen (Preprint 24C, *Symposium on Selected Papers*, part III, 61st Ann. Mtg. AIChE, Los Angeles, Dec. 1–5, 1968) for spheres settling in shear-thinning liquids, and by Ito and Kajuchi (*J. Chem. Eng. Japan*, **2**[1], 19–24 [1969]) and Pazwash and Robertson (*J. Hydraul. Res.*, **13**, 35–55 [1975]) for spheres settling in Bingham plastics. Beris, Tsamopoulos, Armstrong, and Brown (*J. Fluid Mech.*, **158** [1985]) present a finite element calculation for creeping motion of a sphere through a Bingham plastic.

**Nonspherical Rigid Particles** The drag on a nonspherical particle depends upon its shape and orientation with respect to the

**TABLE 6-8 Free-Fall Orientation of Particles**

| Reynolds number <sup>o</sup> | Orientation   |
|------------------------------|---|
| 0.1-5.5                      | All orientations are stable when there are three or more perpendicular axes of symmetry.  |
| 5.5-200                      | Stable in position of maximum drag.   |
| 200-500                      | Unpredictable. Disks and plates tend to wobble, while fuller bluff bodies tend to rotate. |
| 500-200,000                  | Rotation about axis of least inertia, frequently coupled with spiral translation.         |

SOURCE: From Becker, *Can. J. Chem. Eng.*, **37**, 85-91 (1959).  
<sup>o</sup>Based on diameter of a sphere having the same surface area as the particle.

direction of motion. The orientation in free fall as a function of Reynolds number is given in Table 6-8.

The drag coefficients for **disks** (flat side perpendicular to the direction of motion) and for **cylinders** (infinite length with axis perpendicular to the direction of motion) are given in Fig. 6-57 as a function of Reynolds number. The effect of length-to-diameter ratio for cylinders in the Newton's law region is reported by Knudsen and Katz (*Fluid Mechanics and Heat Transfer*, McGraw-Hill, New York, 1958).

Pettyjohn and Christiansen (*Chem. Eng. Prog.*, **44**, 157-172 [1948]) present correlations for the effect of particle shape on free-settling velocities of **isometric particles**. For  $Re < 0.05$ , the terminal or free-settling velocity is given by

$$u_t = K_1 \frac{gd_s^2(\rho_p - \rho)}{18\mu} \quad (6-238)$$

$$K_1 = 0.843 \log \left( \frac{\psi}{0.065} \right) \quad (6-239)$$

where  $\psi$  = sphericity, the surface area of a sphere having the same volume as the particle, divided by the actual surface area of the particle;  $d_s$  = equivalent diameter, equal to the diameter of the equivalent sphere having the same volume as the particle; and other variables are as previously defined.

In the **Newton's law region**, the terminal velocity is given by

$$u_t = \sqrt{\frac{4d_s(\rho_p - \rho)g}{3K_3\rho}} \quad (6-240)$$

$$K_3 = 5.31 - 4.88\psi \quad (6-241)$$

Equations (6-238) to (6-241) are based on experiments on cube-octahedrons, octahedrons, cubes, and tetrahedrons for which the sphericity  $\psi$  ranges from 0.906 to 0.670, respectively. See also Clift, Grace, and Weber. A graph of drag coefficient vs. Reynolds number with  $\psi$  as a parameter may be found in Brown, et al. (*Unit Operations*, Wiley, New York, 1950) and in Govier and Aziz.

For particles with  $\psi < 0.67$ , the correlations of Becker (*Can. J. Chem. Eng.*, **37**, 85-91 [1959]) should be used. Reference to this paper is also recommended for **intermediate region** flow. Settling characteristics of nonspherical particles are discussed by Clift, Grace, and Weber, Chaps. 4 and 6.

The terminal velocity of **axisymmetric particles in axial motion** can be computed from Bowen and Masliyah (*Can. J. Chem. Eng.*, **51**, 8-15 [1973]) for low-Reynolds number motion:

$$u_t = \frac{V'}{K_2} \frac{gD_s^2(\rho_p - \rho)}{18\mu} \quad (6-242)$$

$$K_2 = 0.244 + 1.035\Sigma - 0.712\Sigma^2 + 0.441\Sigma^3 \quad (6-243)$$

where  $D_s$  = diameter of sphere with perimeter equal to maximum particle projected perimeter

$V'$  = ratio of particle volume to volume of sphere with diameter  $D_s$

$\Sigma$  = ratio of surface area of particle to surface area of a sphere with diameter  $D_s$

and other variables are as defined previously.

**FIG. 6-58** Values of exponent  $n$  for use in Eq. (6-242). (From Maude and Whitmore, *Br. J. Appl. Phys.*, **9**, 481 [1958]. Courtesy of the Institute of Physics and the Physical Society.)

**Hindered Settling** When particle concentration increases, particle settling velocities decrease because of hydrodynamic interaction between particles and the upward motion of displaced liquid. The suspension viscosity increases. Hindered settling is normally encountered in sedimentation and transport of concentrated slurries. Below 0.1 percent volumetric particle concentration, there is less than a 1 percent reduction in settling velocity. Several expressions have been given to estimate the effect of particle volume fraction on settling velocity. Maude and Whitmore (*Br. J. Appl. Phys.*, **9**, 477-482 [1958]) give, for uniformly sized spheres,

$$u_t = u_{t0}(1 - c)^n \quad (6-244)$$

where  $u_t$  = terminal settling velocity

$u_{t0}$  = terminal velocity of a single sphere (infinite dilution)

$c$  = volume fraction solid in the suspension

$n$  = function of Reynolds number  $Re_p = d_p u_{t0} \rho / \mu$  as given Fig. 6-58

In the Stokes' law region ( $Re_p < 0.3$ ),  $n = 4.65$  and in the Newton's law region ( $Re_p > 1,000$ ),  $n = 2.33$ . Equation (6-244) may be applied to particles of any size in a polydisperse system, provided the volume fraction corresponding to all the particles is used in computing terminal velocity (Richardson and Shabi, *Trans. Inst. Chem. Eng. [London]*, **38**, 33-42 [1960]). The concentration effect is greater for nonspherical and angular particles than for spherical particles (Steinour, *Ind. Eng. Chem.*, **36**, 840-847 [1944]). Theoretical developments for low-Reynolds number flow assemblages of spheres are given by Happel and Brenner (*Low Reynolds Number Hydrodynamics*, Prentice-Hall, Englewood Cliffs, N.J., 1965) and Famularo and Happel (*AIChE J.*, **11**, 981 [1965]) leading to an equation of the form

$$u_t = \frac{u_{t0}}{1 + \gamma c^{1/3}} \quad (6-245)$$

where  $\gamma$  is about 1.3. As particle concentration increases, resulting in interparticle contact, hindered settling velocities are difficult to predict. Thomas (*AIChE J.*, **9**, 310 [1963]) provides an empirical expression reported to be valid over the range  $0.08 < u_t/u_{t0} < 1$ :

$$\ln \left( \frac{u_t}{u_{t0}} \right) = -5.9c \quad (6-246)$$

**Time-dependent Motion** The time-dependent motion of particles is computed by application of Newton's second law, equating the rate of change of particle motion to the net force acting on the particle. Rotation of particles may also be computed from the net torque. For large particles moving through low-density gases, it is usually sufficient to compute the force due to fluid drag from the

relative velocity and the drag coefficient computed for steady flow conditions. For two- and three-dimensional problems, the velocity appearing in the particle Reynolds number and the drag coefficient is the amplitude of the relative velocity. The drag force, not the relative velocity, is to be resolved into vector components to compute the particle acceleration components. Clift, Grace, and Weber (*Bubbles, Drops and Particles*, Academic, London, 1978) discuss the complexities that arise in the computation of transient drag forces on particles when the transient nature of the flow is important. Analytical solutions for the case of a single particle in creeping flow ( $Re_p = 0$ ) are available. For example, the creeping motion of a spherical particle released from rest in a stagnant fluid is described by

$$\rho_p V \frac{dU}{dt} = g(\rho_p - \rho)V - 3\pi\mu d_p U - \frac{\rho}{2} V \frac{dU}{dt} - \left(\frac{3}{2}\right) d_p^3 \sqrt{\pi\mu} \int_0^t \frac{(dU/dt)_{t-s} ds}{\sqrt{t-s}} \quad (6-247)$$

Here,  $U$  = particle velocity, positive in the direction of gravity, and  $V$  = particle volume. The first term on the right-hand side is the net gravitational force on the particle, accounting for buoyancy. The second is the steady-state Stokes drag (Eq. 6-231). The third is the **added mass** or **virtual mass** term, which may be interpreted as the inertial effect of the fluid which is accelerated along with the particle. The volume of the added mass of fluid is half the particle volume. The last term, the **Basset force**, depends on the entire history of the transient motion, with past motions weighted inversely with the square root of elapsed time. Clift, et al. provide integrated solutions. In **turbulent flows**, particle velocity will closely follow fluid eddy velocities when (Clift et al.)

$$\tau_0 \gg \frac{d_p^2[(2\rho_p/\rho) + 1]}{36\nu} \quad (6-248)$$

where  $\tau_0$  = oscillation period or eddy time scale, the right-hand side expression is the **particle relaxation time**, and  $\nu$  = kinematic viscosity.

**Gas Bubbles** Fluid particles, unlike rigid solid particles, may undergo deformation and internal circulation. Figure 6-59 shows rise velocity data for air bubbles in stagnant water. In the figure,  $Eo = Eotvos\ number, g(\rho_L - \rho_G)d_b/\sigma$ , where  $\rho_L$  = liquid density,  $\rho_G$  = gas density,  $d_b$  = bubble diameter,  $\sigma$  = surface tension, and the equivalent diameter  $d_e$  is the diameter of a sphere with volume equal to that of

the bubble. Small bubbles (<1-mm [0.04-in] diameter) remain spherical and rise in straight lines. The presence of surface active materials generally renders small bubbles rigid, and they rise roughly according to the drag coefficient and terminal velocity equations for spherical solid particles. Bubbles roughly in the range 2- to 8-mm (0.079- to 0.32-in) diameter assume flattened, ellipsoidal shape, and rise in a zig-zag or spiral pattern. This motion increases dissipation and drag, and the rise velocity may actually decrease with increasing bubble diameter in this region, characterized by rise velocities in the range of 20 to 30 cm/s (0.7 to 1.0 ft/s). Large bubbles, >8-mm (0.32-in) diameter, are greatly deformed, assuming a mushroomlike, spherical cap shape. These bubbles are unstable and may break into smaller bubbles. Carefully purified water, free of surface active materials, allows bubbles to freely circulate even when they are quite small. Under creeping flow conditions  $Re_b = d_b\mu_L/\mu_L < 1$ , where  $u_r$  = bubble rise velocity and  $\mu_L$  = liquid viscosity, the bubble rise velocity may be computed analytically from the Hadamard-Rybczynski formula (Levich, *Physicochemical Hydrodynamics*, Prentice-Hall, Englewood Cliffs, N.J., 1962, p. 402). When  $\mu_G/\mu_L \ll 1$ , which is normally the case, the rise velocity is 1.5 times the rigid sphere Stokes law velocity. However, in practice, most liquids, including ordinary distilled water, contain sufficient surface active materials to render small bubbles rigid. Larger bubbles undergo deformation in both purified and ordinary liquids; however, the variation in rise velocity for large bubbles with degree of purity is quite evident in Fig. 6-59. For additional discussion, see Clift, et al., Chap. 7.

Karamanev [op. cit.] provided equations for bubble rise velocity based on the Archimedes number and on use of the bubble projected diameter  $d_b$  in the drag coefficient and the bubble equivalent diameter in  $Ar$ . The Archimedes number is as defined in Eq. (6-236) except that the density difference is liquid density minus gas density, and  $d_p$  is replaced by  $d_e$ .

$$u_r = 40.3 \frac{d_e}{d_h} \sqrt{\frac{V^{1/3}}{C_D}} = 40.3 \frac{d_e}{d_h} \sqrt{\frac{(\pi d_e^3/6)^{1/3}}{C_D}} \quad (6-249)$$

$$C_D = \frac{432}{Ar} (1 + 0.0470 Ar^{2/3}) + \frac{0.517}{1 + 154 Ar^{-1/3}} \quad Ar < 13,000 \quad (6-250)$$

$$C_D = 0.95 \quad Ar > 13,000 \quad (6-251)$$

FIG. 6-59 Terminal velocity of air bubbles in water at 20°C. (From Clift, Grace, and Weber, *Bubbles, Drops and Particles*, Academic, New York, 1978).

FIG. 6-60 Drag coefficient for water drops in air and air bubbles in water. Standard drag curve is for rigid spheres. (From Clift, Grace, and Weber, *Bubbles, Drops and Particles*, Academic, New York, 1978.)

$$\frac{d_c}{d_h} = (1 + 0.163Eo^{0.757})^{-1/3} \quad Eo < 40 \quad (6-252)$$

$$\frac{d_c}{d_h} = 0.62 \quad Eo > 40 \quad (6-253)$$

Applied to air bubbles in water, these expressions give reasonable agreement with the contaminated water curve in Fig. 6-59.

Figure 6-60 gives the drag coefficient as a function of bubble or drop Reynolds number for air bubbles in water and water drops in air, compared with the standard drag curve for rigid spheres. Information on bubble motion in **non-Newtonian** liquids may be found in Astarita and Apuzzo (*AIChE J.*, **11**, 815-820 [1965]); Calderbank, Johnson, and Loudon (*Chem. Eng. Sci.*, **25**, 235-256 [1970]); and Acharya, Mashelkar, and Ulbrecht (*Chem. Eng. Sci.*, **32**, 863-872 [1977]).

**Liquid Drops in Liquids** Very small liquid drops in immiscible liquids behave like rigid spheres, and the terminal velocity can be approximated by use of the drag coefficient for solid spheres up to a Reynolds number of about 10 (Warshay, Bogusz, Johnson, and Kintner, *Can. J. Chem. Eng.*, **37**, 29-36 [1959]). Between Reynolds numbers of 10 and 500, the terminal velocity exceeds that for rigid spheres owing to internal circulation. In normal practice, the effect of drop phase viscosity is neglected. Grace, Wairegi, and Nguyen (*Trans. Inst. Chem. Eng.*, **54**, 167-173 [1976]; Clift, et al., op. cit., pp. 175-177) present a correlation for terminal velocity valid in the range

$$M < 10^{-3} \quad Eo < 40 \quad Re > 0.1 \quad (6-254)$$

- where  $M$  = Morton number =  $g\mu^4\Delta\rho/\rho^2\sigma^3$
- $Eo$  = Eotvos number =  $g\Delta\rho d^2/\sigma$
- $Re$  = Reynolds number =  $d\rho u/\mu$
- $\Delta\rho$  = density difference between the phases
- $\rho$  = density of continuous liquid phase
- $d$  = drop diameter
- $\mu$  = continuous liquid viscosity
- $\sigma$  = surface tension
- $u$  = relative velocity

The correlation is represented by

$$J = 0.94H^{0.757} \quad (2 < H \leq 59.3) \quad (6-255)$$

$$J = 3.42H^{0.441} \quad (H > 59.3) \quad (6-256)$$

where 
$$H = \frac{4}{3} EoM^{-0.149} \left( \frac{\mu}{\mu_w} \right)^{-0.14} \quad (6-257)$$

$$J = ReM^{0.149} + 0.857 \quad (6-258)$$

Note that the terminal velocity may be evaluated explicitly from

$$u = \frac{\mu}{\rho d} M^{-0.149} (J - 0.857) \quad (6-259)$$

In Eq. (6-257),  $\mu$  = viscosity of continuous liquid and  $\mu_w$  = viscosity of water, taken as 0.9 cP (0.0009 Pa · s).

For drop velocities in non-Newtonian liquids, see Mhatre and Kintner (*Ind. Eng. Chem.*, **51**, 865-867 [1959]); Marrucci, Apuzzo, and Astarita (*AIChE J.*, **16**, 538-541 [1970]); and Mohan, et al. (*Can. J. Chem. Eng.*, **50**, 37-40 [1972]).

**Liquid Drops in Gases** Liquid drops falling in stagnant gases appear to remain spherical and follow the rigid sphere drag relationships up to a Reynolds number of about 100. Large drops will deform,

FIG. 6-61 Terminal velocities of spherical particles of different densities settling in air and water at 70°F under the action of gravity. To convert ft/s to m/s, multiply by 0.3048. (From Lapple, et al., *Fluid and Particle Mechanics*, University of Delaware, Newark, 1951, p. 292.)

## 6-56 FLUID AND PARTICLE DYNAMICS

with a resulting increase in drag, and in some cases will shatter. The largest water drop which will fall in air at its terminal velocity is about 8 mm (0.32 in) in diameter, with a corresponding velocity of about 9 m/s (30 ft/s). Drops shatter when the Weber number defined as

$$We = \frac{\rho_C u^2 d}{\sigma} \quad (6-260)$$

exceeds a critical value. Here,  $\rho_C$  = gas density,  $u$  = drop velocity,  $d$  = drop diameter, and  $\sigma$  = surface tension. A value of  $We_c = 13$  is often cited for the critical Weber number.

Terminal velocities for water drops in air have been correlated by Berry and Prnager (*J. Appl. Meteorol.*, **13**, 108–113 [1974]) as

$$Re = \exp [-3.126 + 1.013 \ln N_D - 0.01912(\ln N_D)^2] \quad (6-261)$$

for  $2.4 < N_D < 10^7$  and  $0.1 < Re < 3,550$ . The dimensionless group  $N_D$  (often called the *Best* number [Clift et al.]) is given by

$$N_D = \frac{4\rho\Delta\rho g d^3}{3\mu^2} \quad (6-262)$$

and is proportional to the similar Archimedes and Galileo numbers.

Figure 6-61 gives calculated settling velocities for solid spherical particles settling in air or water using the standard drag coefficient curve for spherical particles. For fine particles settling in air, the **Stokes-Cunningham correction** has been applied to account for particle size comparable to the mean free path of the gas. The correction is less than 1 percent for particles larger than 16  $\mu\text{m}$  settling in air. Smaller particles are also subject to **Brownian motion**. Motion of particles smaller than 0.1  $\mu\text{m}$  is dominated by Brownian forces and gravitational effects are small.

**Wall Effects** When the diameter of a settling particle is significant compared to the diameter of the container, the settling velocity is

**TABLE 6-9 Wall Correction Factor for Rigid Spheres in Stokes' Law Region**

| $\beta^\circ$ | $k_w$ | $\beta$ | $k_w$  |
|---------------|-------|---------|--------|
| 0.0           | 1.000 | 0.4     | 0.279  |
| 0.05          | 0.885 | 0.5     | 0.170  |
| 0.1           | 0.792 | 0.6     | 0.0945 |
| 0.2           | 0.596 | 0.7     | 0.0468 |
| 0.3           | 0.422 | 0.8     | 0.0205 |

SOURCE: From Haberman and Sayre, *David W. Taylor Model Basin Report* 1143, 1958.

\* $\beta$  = particle diameter divided by vessel diameter.

reduced. For rigid spherical particles settling with  $Re < 1$ , the correction given in Table 6-9 may be used. The factor  $k_w$  is multiplied by the settling velocity obtained from Stokes' law to obtain the corrected settling rate. For values of diameter ratio  $\beta$  = particle diameter/vessel diameter less than 0.05,  $k_w = 1/(1 + 2.1\beta)$  (Zenz and Othmer, *Fluidization and Fluid-Particle Systems*, Reinhold, New York, 1960, pp. 208–209). In the range  $100 < Re < 10,000$ , the computed terminal velocity for rigid spheres may be multiplied by  $k'_w$  to account for wall effects, where  $k'_w$  is given by (Harmathy, *AIChE J.*, **6**, 281 [1960])

$$k'_w = \frac{1 - \beta^2}{\sqrt{1 + \beta^4}} \quad (6-263)$$

For gas bubbles in liquids, there is little wall effect for  $\beta < 0.1$ . For  $\beta > 0.1$ , see Uto and Kintner (*AIChE J.*, **2**, 420–424 [1956]), Maneri and Mendelson (*Chem. Eng. Prog.*, **64**, *Symp. Ser.*, **82**, 72–80 [1968]), and Collins (*J. Fluid Mech.*, **28**, part 1, 97–112 [1967]).

## Nomenclature and Units

The component A is identified by the subscript  $a$ . Thus, the number of moles is  $n_a$ ; the fractional conversion is  $X_a$ ; the extent of reaction is  $\zeta_a$ ; the partial pressure is  $p$ ; the rate of consumption is  $r_a$ ; the molar flow rate is  $N_a$ ; the volumetric flow rate is  $q$ ; reactor volume is  $V_r$  or simply  $V$  for batch reactors; the volumetric concentration is  $C_a = n_a/V$  or  $C_a = N_a/q$ ; the total pressure is  $P$ ; and the temperature is  $T$ . Throughout this section, equations are presented without specification of units. Use of any consistent unit set is appropriate.

Following is a listing of typical nomenclature expressed in SI and U.S. Customary System units.

| Symbol         | Definition   | SI units              | U.S. Customary System units | Symbol        | Definition  | SI units               | U.S. Customary System units |
|----------------|--|-----------------------|-----------------------------|---------------|---|------------------------|-----------------------------|
| A, B, C, . . . | Names of substances  |                       |                             | $p_a$         | Partial pressure of substance A   | Pa                     | psi                         |
| A              | Free radical, as CH <sub>3</sub>   |                       |                             | $q$           | Volumetric flow rate  | m <sup>3</sup> /s      | ft <sup>3</sup> /s          |
| $a$            | Activity   |                       |                             | $Q$           | Electric charge   | Coulomb                |                             |
| BR             | Batch reactor  |                       |                             | $\bar{R}$     | Radial position, radius, universal gas constant   |                        |                             |
| $b$            | Estimate of kinetic parameters, vector   |                       |                             | Re            | Reynolds number   |                        |                             |
| $C_a$          | Concentration of substance A   | kg·mol/m <sup>3</sup> | lb·mol/ft <sup>3</sup>      | RgSS          | Regression sum of squares   |                        |                             |
| CSTR           | Continuous stirred tank reactor  |                       |                             | RSS           | Residual sum of squares   |                        |                             |
| $C_0$          | Initial concentration  | kg·mol/m <sup>3</sup> | lb·mol/ft <sup>3</sup>      | $r_a$         | Rate of reaction of A per unit volume   |                        |                             |
| $c_p$          | Heat capacity at constant pressure   | kJ/(kg·K)             | Btu/(lbm·°F)                | S             | Selectivity, stoichiometric matrix, objective function for parameter estimation   |                        |                             |
| $\Delta c_p$   | Heat capacity change in a reaction   | kJ/(kg·K)             | Btu/(lbm·°F)                | SBR           | Semibatch reactor   |                        |                             |
| $D$            | Diffusivity, dispersion coefficient  | m <sup>2</sup> /s     | ft <sup>2</sup> /s          | Sc            | Schmidt number  |                        |                             |
| $D_e$          | Effective diffusivity  | m <sup>2</sup> /s     | ft <sup>2</sup> /s          | Sh            | Sherwood number   |                        |                             |
| $D_K$          | Knudsen diffusivity  | m <sup>2</sup> /s     | ft <sup>2</sup> /s          | $\Delta S$    | Entropy change  | kJ/(kg·mol·K)          | Btu/(lb·mol·R)              |
| DP             | Degree of polymerization   |                       |                             | $s$           | Estimate of variance  |                        |                             |
| $E$            | Activation energy, enhancement factor for gas-liquid mass transfer with reaction, electrochemical cell potential           |                       |                             | $t$           | Time, $t$ statistic   |                        |                             |
| $F$            | Faraday constant, $F$ statistic  |                       |                             | $u$           | Linear velocity   | m/s                    | ft/s                        |
| $f$            | Efficiency of initiation in polymerization   |                       |                             | $V$           | Volume of reactor, variance-covariance matrix   |                        |                             |
| $f_a$          | $C_a/C_{a0}$ or $n_a/n_{a0}$ , fraction of A remaining unconverted   |                       |                             | $v$           | Molar volume  | m <sup>3</sup> /kg·mol | ft <sup>3</sup> /lb·mol     |
| Ha             | Hatta number   |                       |                             | WCLD          | Weight chain length distribution  |                        |                             |
| He             | Henry constant for absorption of gas in liquid   |                       |                             | WMMD          | Weight molecular weight distribution  |                        |                             |
| $\Delta G$     | Free energy change   | kJ/kg·mol             | Btu/lb·mol                  | X             | Linear model matrix for parameter estimation, fractional conversion   |                        |                             |
| $\Delta H_r$   | Heat of reaction   | kJ/kg·mol             | Btu/lb·mol                  | $X_a$         | $1 - f_a = 1 - C_a/C_{a0}$ or $1 - n_a/n_{a0}$ , fraction of A converted  |                        |                             |
| $I$            | Initiator for polymerization, modified Bessel functions, electric current  |                       |                             | $x$           | Axial position in a reactor, mole fraction in liquid  | Variable               |                             |
| $j$            | Electric current density   | A/m <sup>2</sup>      |                             | $Y$           | Yield; yield coefficient for biochemical reactions  |                        |                             |
| $K_a$          | Adsorption constant  |                       |                             | $y$           | Mole fraction in gas, predicted dependent variable  |                        |                             |
| $K_e$          | Chemical equilibrium constant  |                       |                             | $z$           | $x/L$ , normalized axial position   |                        |                             |
| $k$            | Specific rate constant of reaction, mass-transfer coefficient  |                       |                             | Greek letters |   |                        |                             |
| $L$            | Length of path in reactor  | m                     | ft                          | $\alpha$      | Fraction of initial catalyst activity, probability of propagation for chain polymerization, confidence level                      |                        |                             |
| LFSS           | Lack of fit sum of squares   |                       |                             | $\beta$       | $r/R$ , normalized radial position, fraction of poisoned catalyst, kinetic parameter vector                                       |                        |                             |
| $M$            | Average molecular weight in polymers, dead polymer species, monomer  |                       |                             | $\delta$      | Film thickness or boundary layer thickness, relative change in number of moles by reaction  |                        |                             |
| $m$            | Number of moles in electrochemical reaction  | kg·mol                | lb·mol                      | $\delta(t)$   | Unit impulse input, Dirac function  |                        |                             |
| $N$            | Molar flow rate, molar flux  |                       |                             | $\epsilon$    | Fraction void space in a packed bed, relative change in number of moles by reaction, residual error, porosity, current efficiency |                        |                             |
| NCLD           | Number chain length distribution   |                       |                             | $\Phi$        | Weisz Prater parameter  |                        |                             |
| NMWD           | Number molecular weight distribution   |                       |                             | $\phi$        | Thiele modulus  |                        |                             |
| $n$            | Number of stages in a CSTR battery, reaction order, number of electrons in electrochemical reaction, number of experiments |                       |                             |               |   |                        |                             |
| $n_a$          | Number of moles of A present   | kg·mol                | lb·mol                      |               |   |                        |                             |
| $n_t$          | Total number of moles  | kg·mol                | lb·mol                      |               |   |                        |                             |
| $P$            | Total pressure, live polymer species   |                       |                             |               |   |                        |                             |
| PESS           | Pure error sum of squares  |                       |                             |               |   |                        |                             |
| PFR            | Plug flow reactor  |                       |                             |               |   |                        |                             |
| $p$            | Number of kinetic parameters   |                       |                             |               |   |                        |                             |

## 7-4 REACTION KINETICS

### Nomenclature and Units (Concluded)

| Symbol       | Definition  | SI units          | U.S. Customary System units | Subscripts    |  |
|--------------|---|-------------------|-----------------------------|---------------|--|
|              |   |                   |                             | Greek letters |  |
| $\eta$       | Effectiveness factor of porous catalyst, overpotential in electrochemical reactions                           |                   |                             | $d$           | Deactivation   |
| $\lambda$    | Parameter for instantaneous gas-liquid reaction, moments in polymer chain length                              |                   |                             | $e$           | Equilibrium  |
| $\mu$        | Viscosity, biomass growth rate, average chain length in polymers  |                   |                             | $f$           | Forward reaction, final, formation   |
| $\nu$        | $\mu/\rho$ , kinematic viscosity, stoichiometric coefficient, fraction of surface covered by adsorbed species |                   |                             | $G$           | Gas  |
| $\theta$     | Dimensionless time  |                   |                             | $i$           | Component $i$  |
| $\rho$       | Density   | kg/m <sup>3</sup> | lbm/ft <sup>3</sup>         | $j$           | Reaction $j$   |
| $\sigma$     | Variance  |                   |                             | $L$           | Liquid   |
| $\tau$       | Residence time, tortuosity factor   |                   |                             | $m$           | Based on mass, mass transfer   |
| $\zeta$      | Extent of reaction  |                   |                             | max           | Maximum biomass growth, maximum extent of reaction                                     |
|              |   |                   |                             | Subscripts    |  |
| act          | Activation  |                   |                             | $n$           | Chain length in polymers   |
| anode        | At anode  |                   |                             | $o$           | Oxidized   |
| $B$          | Bed   |                   |                             | obs           | observed   |
| cathode      | At cathode  |                   |                             | $p$           | Particle   |
| cell         | Electrochemical cell  |                   |                             | projected     | Electrode projected area   |
| current, $j$ | Current, species $j$  |                   |                             | $r$           | Reverse reaction, reduced  |
| $D$          | Diffusion, dispersion   |                   |                             | $S$           | Substrate  |
|              |   |                   |                             | Superscripts  |  |
|              |   |                   |                             | $s$           | Solid or catalyst, saturation, surface   |
|              |   |                   |                             | surf          | Surface  |
|              |   |                   |                             | $v$           | Based on volume  |

The mechanism and corresponding kinetics provide the rate at which the chemical or biochemical species in the reactor system react at the prevailing conditions of temperature, pressure, composition, mixing, flow, heat, and mass transfer. Observable kinetics represent the true intrinsic chemical kinetics only when competing phenomena such as transport of mass and heat are not limiting the rates. The intrinsic chemical mechanism and kinetics are unique to the reaction system. Knowledge of the intrinsic kinetics therefore facilitates reactor selection, choice of optimal operating conditions, and reactor scale-up and design, when combined with understanding of the associated physical and transport phenomena for different reactor scales and types.

This section covers the following key aspects of reaction kinetics:

- Chemical mechanism of a reaction system and its relation to kinetics
- Intrinsic rate data using equations that can be correlative, lumped, or based on detailed elementary kinetics
- Catalytic kinetics
- Effect of mass transfer on kinetics in heterogeneous systems
- Intrinsic kinetic rates from experimental data and/or from theoretical calculations
- Kinetic parameter estimation

The use of reaction kinetics for analyzing and designing suitable reactors is discussed in Sec. 19.

## BASIC CONCEPTS

### MECHANISM

The mechanism describes the reaction steps and the relationship between the reaction rates of the chemical components. A single chemical reaction includes reactants  $A, B, \dots$  and products  $R, S, \dots$

where  $\nu_i$  are the *stoichiometric coefficients* of components  $A, B, \dots$ , i.e., the relative number of molecules of  $A, B, \dots$  that participate in the reaction. For instance, the HBr synthesis has the global stoichiometry  $\text{H}_2 + \text{Br}_2 \rightleftharpoons 2\text{HBr}$ .

The *stoichiometry* of the reaction defines the reaction elemental balance (atoms of H and Br, for instance) and therefore relates the number of molecules of reactants and products participating in the reaction. The stoichiometric coefficients are not unique for a given reaction, but their ratios are unique. For instance, for the HBr synthesis above we could have written the stoichiometric equation  $\frac{1}{2}\text{H}_2 + \frac{1}{2}\text{Br}_2 \rightleftharpoons \text{HBr}$  as well.

Often several reactions occur simultaneously, resulting in a *network of reactions*. When the network is broken down into *elementary* or *single-event* steps (such as a single electron transfer), the network represents the *true mechanism* of the chemical transformations leading from initial reactants to final products through intermediates. The intermediates can be molecules, ions, free radicals, transition state complexes, and other moieties. A network of *global reactions*, with each reaction representing the combination of a number of elementary steps, does not represent the true mechanism of the chemical transformation but is still useful for global reaction rate calculations, albeit empirically. The stoichiometry can only be written in a unique manner for elementary reactions, since as shown later, the reaction rate for elementary reactions is determined directly by the stoichiometry through the concept of the law of mass action.

### REACTION RATE

The *specific rate* of consumption or production of any reaction species  $i$ ,  $r_i$ , is the rate of change of the number of molecules of species  $i$  with time per unit volume of reaction medium:

$$r_i = \frac{1}{V} \frac{dn_i}{dt} \quad (7-2)$$

The rate is negative when  $i$  represents a *reactant* ( $dn_i/dt$  is negative since  $n_i$  is decreasing with time) and positive when  $i$  represents a *product*

( $dn_i/dt$  positive since  $n_i$  is increasing with time). The specific rate of a reaction, e.g., that in Eq. (7-1) is defined as

$$\begin{aligned} r &= -r_i/\nu_i && \text{for reactants} \\ r &= r_i/\nu_i && \text{for products} \end{aligned} \quad (7-3)$$

By this definition, the specific rate of reaction is uniquely defined, and its sign is always positive. Inversely, the rate of reaction of each component or species participating in the reaction is the specific reaction rate multiplied by the species' stoichiometric coefficient with the corrected sign (negative for reactants, positive for products).

### CLASSIFICATION OF REACTIONS

Reactions can be classified in several ways. On the basis of *mechanism* they may be

1. *Irreversible*, i.e., the reverse reaction rate is negligible:  $A + B \Rightarrow C + D$ , e.g., CO oxidation  $\text{CO} + \frac{1}{2}\text{O}_2 \Rightarrow \text{CO}_2$
2. *Reversible*:  $A + B \rightleftharpoons C + D$ , e.g., the water-gas shift  $\text{CO} + \text{H}_2\text{O} \rightleftharpoons \text{CO}_2 + \text{H}_2$
3. *Equilibrium*, a special case with zero net rate, i.e., with the forward and reverse reaction rates of a reversible reaction being equal. All reversible reactions, if left to go to completion, end in equilibrium.
4. *Networks of simultaneous reactions*, i.e., consecutive, parallel, complex (combination of consecutive and parallel reactions):

e.g., two-step hydrogenation of acetylene to ethane

A further classification is from the point of view of the number of reactant molecules participating in the reaction, or the *molecularity*:

1. *Unimolecular*:  $A \Rightarrow B$ , e.g., isomerization of ortho-xylene to para-xylene, O-xylene to P-xylene, or  $A \Rightarrow B + C$ , e.g., decomposition  $\text{CaCO}_3 \Rightarrow \text{CaO} + \text{CO}_2$
2. *Bimolecular*:  $A + B \Rightarrow C$  or  $2A \Rightarrow B$  or  $A + B \Rightarrow C + D$ , e.g.,  $\text{C}_2\text{H}_4 + \text{H}_2 \Rightarrow \text{C}_2\text{H}_6$
3. *Trimolecular*:  $A + B + C \Rightarrow D$  or  $3A \Rightarrow B$

This last classification has fundamental meaning only when considering elementary reactions, i.e., reactions that constitute a single chemical transformation or a single event, such as a single electron transfer. For elementary reactions, molecularity is rarely higher than 2. Often elementary reactions are not truly unimolecular, since in order for the reaction to occur, energy is required and it is obtained through collision with other molecules such as an inert solvent or gas.

## 7-6 REACTION KINETICS

Thus the unimolecular reaction  $A \Rightarrow B$  could in reality be represented as a bimolecular reaction  $A + X \Rightarrow B + X$ , i.e.,  $A$  collides with  $X$  to produce  $B$  and  $X$ , and thus no net consumption of  $X$  occurs.

Reactions can be further classified according to the *phases* present. Examples for the more common cases are

1. *Homogeneous gas*, e.g., methane combustion
2. *Homogeneous liquid*, e.g., acid/base reactions to produce soluble salts
3. *Heterogeneous gas-solid*, e.g., HCN synthesis from  $\text{NH}_3$ ,  $\text{CH}_4$ , and air on a solid catalyst
4. *Heterogeneous gas-liquid*, e.g., absorption of  $\text{CO}_2$  in amine solutions
5. *Heterogeneous liquid-liquid*, e.g., reaction in immiscible organic and aqueous phases such as synthesis of adipic acid from cyclohexanone and nitric acid
6. *Heterogeneous liquid-solid*, e.g., reaction of limestone with sulfuric acid to make gypsum
7. *Heterogeneous solid-solid*, e.g., self-propagating, high-temperature synthesis of inorganic pure oxides (SHS)
8. *Heterogeneous gas-liquid-solid*, e.g., catalytic Fischer-Tropsch synthesis of hydrocarbons from  $\text{CO}$  and  $\text{H}_2$
9. *Heterogeneous gas-liquid-liquid*, e.g., oxidations or hydrogenations with phase transfer catalysts

Reactions can also be classified with respect to the *mode of operation* in the reaction system as

1. *Isothermal constant volume* (batch)
2. *Isothermal constant pressure* (continuous)
3. *Adiabatic*
4. *Nonisothermal* temperature-controlled (by cooling or heating), batch or continuous

### EFFECT OF CONCENTRATION ON RATE

The *concentration* of the reaction components determines the rate of reaction. For instance, for the irreversible reaction

the rate can be represented *empirically* as a power law function of the reactant concentrations such as

$$r = kC_a^a C_b^b \quad C_i = \frac{n_i}{V} \quad (7-5)$$

The exponents  $a$  and  $b$  represent the *order of the reaction* with respect to components  $A$  and  $B$ , and the *sum*  $a + b$  represents the *overall order of the reaction*. The order can be a positive, zero, or negative number indicating that the rate increases, is independent of, or decreases with an increase in a species concentration, respectively. The exponents can be whole (integral order) or fraction (fractional order). In Eq. (7-5)  $k$  is the *specific rate constant* of the reaction, and it is independent of concentrations for elementary reactions only. For global reactions consisting of several elementary steps,  $k$  may still be constant over a narrow range of compositions and operating conditions and therefore can be considered constant for limited practical purposes. A further complexity arises for nonideal chemical solutions where activities have to be used instead of concentrations. In this case the rate constant can be a function of composition even for elementary steps (see, for instance, Froment and Bischoff, *Chemical Reactor Analysis and Design*, Wiley, 1990).

When Eq. (7-4) represents a global reaction combining a number of elementary steps, then rate equation (7-5) represents an empirical correlation of the global or overall reaction rate. In this case exponents  $a$  and  $b$  have no clear physical meaning other than indicating the overall effect of the various concentrations on rate, and they do not have any obvious relationship to the stoichiometric coefficients  $p$  and  $q$ . This is not so for elementary reactions, as shown in the next subsection. Also, as shown later, power law and rate expressions other than power law (e.g., hyperbolic) can be developed for specific reactions by starting with the mechanism of the elementary steps and making simplifying assumptions that are valid under certain conditions.

### LAW OF MASS ACTION

As indicated above, the dependence of rate on concentration can be shown to be of the general form

$$r = kf(C_a, C_b, \dots) \quad (7-6)$$

For elementary reactions, the *law of mass action* states that the rate is proportional to the concentrations of the reactants raised to the power of their respective molecularity. Thus for an elementary irreversible reaction such as (7-4) the rate equation is

$$r = kC_a^p C_b^q \quad (7-7)$$

Hence, the exponents  $p$  and  $q$  of Eq. (7-7) are the stoichiometric coefficients when the stoichiometric equation truly represents the mechanism of reaction, i.e., when the reactions are elementary. As discussed above, the exponents  $a$  and  $b$  in Eq. (7-5) identify the order of the reaction, while the stoichiometric coefficients  $p$  and  $q$  in Eq. (7-7) also identify the molecularity—for elementary reactions these are the same.

### EFFECT OF TEMPERATURE

The *Arrhenius equation* relates the specific rate constant to the absolute temperature

$$k = k_0 \exp\left(-\frac{E}{RT}\right) \quad (7-8)$$

where  $E$  is called the *activation energy* and  $k_0$  is the *preexponential factor*. As seen from Eq. (7-8), the rate can be a very strongly increasing (exponential) function of temperature, depending on the magnitude of the activation energy  $E$ . This equation works well for elementary reactions, and it also works reasonably well for global reactions over a relatively narrow range of temperatures in the absence of mass-transfer limitations. The Arrhenius form represents an energy barrier on the reaction pathway between reactants and products that has to be overcome by the reactant molecules.

The Arrhenius equation can be derived from theoretical considerations using either of two competing theories, the *collision theory* and the *transition state theory*. A more accurate form of Eq. (7-8) includes an additional temperature factor

$$k = k_0 T^m \exp\left(-\frac{E}{RT}\right) \quad 0 < m < 1 \quad (7-9)$$

but the  $T^m$  factor is often neglected because of the usually much stronger dependence on temperature of the exponential factor in Eq. (7-9), as  $m$  is usually small. When  $m$  is larger, as it can be for complex molecules, then the  $T^m$  term has to be taken into consideration. For more details, see Masel, *Chemical Kinetics and Catalysis*, Wiley, 2001; Levenspiel, *Chemical Reaction Engineering*, 3d ed., Wiley, 1999).

### HEAT OF REACTION

Chemical reactions are accompanied by evolution or absorption of energy. The enthalpy change (difference between the total enthalpy of formation of the products and that of the reactants) is called the *heat of reaction*  $\Delta H_r$ :

$$\Delta H_r = (v_r H_{fr} + v_s H_{fs} + \dots) - (v_a H_{fa} + v_b H_{fb} + \dots) \quad (7-10)$$

where  $H_{fi}$  are the *enthalpies of formation* of components  $i$ . The reaction is *exothermic* if heat is produced by the reaction (negative heat of reaction) and *endothermic* if heat is consumed (positive heat of reaction). The magnitude of the effective heat of reaction depends upon temperature and the phases of the reactants and product. To estimate the dependence of the heat of reaction on temperature relative to a

reference temperature  $T_0$ , the following expression can be used, provided there is no phase change:

$$\Delta H_r(T) = \Delta H_r(T_0) + \int_{T_0}^T \Delta c_p dT \quad (7-11)$$

$$\Delta c_p = (v_a c_{p_a} + v_b c_{p_b} + \dots) - (v_a c_{p_a} + v_b c_{p_b} + \dots)$$

where  $c_{p_i}$  are the *heat capacities* of component  $i$ . The heat of reaction can be measured by using calorimetry, or it can be calculated by using a variety of thermodynamic methods out of the scope of this chapter (see relevant sections of this handbook, thermodynamic texts, and Bird, Stewart, and Lightfoot, *Transport Phenomena*, 2d ed., John Wiley & Sons, New York, 2002). It is important to accurately capture the energy balance and its relation to the heat of reaction and heat capacities (see also Denn, *Process Modeling*, Langman, New York, 1986, for correct formulations). The coupling of the heat of reaction with the reaction rate through the Arrhenius equation often has a dominating effect on reactor selection and control, and on the laboratory reactor setup required to obtain accurate intrinsic kinetics and mechanism. More on this can be found in Sec. 19.

**CHEMICAL EQUILIBRIUM**

Often reactions or reaction steps in a network of reactions are at chemical equilibrium; i.e., the rate of the forward reaction equals the rate of the reverse reaction. For instance, for the reversible reaction

with mass action kinetics, the rate may be written as

$$r = r_f - r_r = k_f C_a^v C_b^v - k_r C_r^v C_s^v \quad (7-13)$$

At chemical equilibrium the forward and reverse reaction rates are equal according to the principle of *microscopic reversibility*:

$$r = r_f - r_r = 0 \quad (7-14)$$

The equilibrium constant  $K_e$  (based on volumetric concentrations) is defined as the ratio of the forward and reverse rate constants and is related to the composition at equilibrium as follows:

$$K_e = \frac{k_f}{k_r} = \frac{C_r^v C_s^v}{C_a^v C_b^v} \quad (7-15)$$

$K_e$  can be calculated from the free energy change of the reaction. Using the van't Hoff relation, we obtain the dependence of  $K_e$  on temperature:

$$\frac{d(\ln K_e)}{dT} = \frac{\Delta H_r}{RT^2} \quad (7-16)$$

Integrating with respect to temperature, we obtain a form similar to the Arrhenius expression of the rate constant for a narrow range of temperature:

$$K_e = K_{e,0} \exp\left(\frac{\Delta H_r}{RT}\right) \quad (7-17)$$

A more general integral form of Eq. (7-16) is

$$\ln K_e(T) = \ln K_e(T_0) + \frac{1}{R} T \int_{T_0}^T \frac{\Delta H_r(T_0) + \int_{T_0}^T \Delta c_p dT}{T^2} dt \quad (7-18)$$

When a reversible reaction is not at equilibrium, knowledge of  $K_e$  can be used to eliminate the rate constant of the reverse reaction by using Eq. (7-15) as follows:

$$r = k_f (C_a^v C_b^v - C_r^v C_s^v / K_e) \quad (7-19)$$

When several reversible reactions occur simultaneously, each reaction  $r_j$  is characterized by its equilibrium constant  $K_{e_j}$ . When the  $K_{e_j}$  are known, the composition at equilibrium can be calculated from a set of equations such as Eq. (7-15) for each reaction.

**CONVERSION, EXTENT OF REACTION, SELECTIVITY, AND YIELD**

*Conversion* of a reactant is the number of moles converted per initial or feed moles of a reactant. Thus for component A

$$X_a = 1 - \frac{n_a}{n_{a0}} \quad (7-20)$$

A *limiting reactant* is a reactant whose concentration at the start of the reaction is the least of all reactants relative to the required stoichiometric amount needed for complete conversion. For instance, for the single reaction (7-12), A is the limiting reactant if the initial molar ratio of concentrations of A and B is less than the ratio of their stoichiometric coefficients:

$$\frac{n_{a0}}{n_{b0}} < \frac{v_a}{v_b} \quad (7-21)$$

Once the limiting reactant is depleted, the respective reaction stops even though other (nonlimiting) reactants may still be abundant.

For each reaction or each step in a network of reactions, a unique *extent of reaction*  $\xi$  that relates the composition of components that participate in the reaction to each other can be defined. For instance, for the single reaction (7-1):

$$\xi = \frac{n_{a0} - n_a}{v_a} = \frac{n_{b0} - n_b}{v_b} = \dots = -\frac{n_{r0} - n_r}{v_r} = -\frac{n_{s0} - n_s}{v_s} = \dots \quad (7-22)$$

The extent of reaction is related to conversion as follows:

$$\xi = \frac{X_a n_{a0}}{v_a} = \frac{X_b n_{b0}}{v_b} = \dots \quad (7-23)$$

When A is the limiting reactant as in Eq. (7-21), the maximum extent of reaction (with A fully converted) is

$$\xi_{\max} = \frac{n_{a0}}{v_a} \quad (7-24)$$

For multiple reactions with reactants participating in more than one reaction, it is more difficult to determine the limiting reactant and often it is necessary to calculate the concentration as the reactions proceed to determine which reactant is consumed first. When the limiting reactant is depleted, all reactions that use this component as reactant stop, and the corresponding rates become zero.

*Selectivity*  $S$  of a product is the ratio of the rate of production of that product to the rate of production of all products combined. For a single reaction selectivity is trivial—if more than one product occurs, then the selectivity of each product is the ratio of the stoichiometric coefficient of that product to the sum of stoichiometric coefficients of all the products. Thus for reaction (7-1)

$$S_r = \frac{v_r}{v_r + v_s + \dots} \quad (7-25)$$

## 7-8 REACTION KINETICS

The selectivity of product  $R$  for a network of reactions, with all the reactions making the various products included, is

$$S_r = \frac{r_r}{\sum_{\text{all products } i} r_i} \quad (7-26)$$

For instance, for the network of reactions  $A + B \xrightarrow{1} C + D$   
 $C + E \xrightarrow{2} F + G$ , the selectivity to product  $C$  is

$$S_c = \frac{r_c}{r_c + r_d + r_f + r_g} = \frac{r_1 - r_2}{(r_1 - r_2) + r_1 + r_2 + r_2} = \frac{r_1 - r_2}{2r_1 + r_2}$$

The *yield*  $Y$  of a product  $R$  with respect to a reactant  $A$  is the ratio of the rate of production of  $R$  to that of consumption of  $A$ :

$$Y_r = \frac{r_r}{-r_a} \quad (7-27)$$

For a single reaction the yield is trivial and Eq. (7-27) simplifies to the ratio of the respective stoichiometric coefficients:

$$Y_r = \frac{v_r}{v_a} \quad (7-28)$$

The yield quantifies the efficiency of the respective reactant utilization to make the desired products.

### CONCENTRATION TYPES

Different concentration types are used for different reaction systems. For gas-phase reactions, *volumetric concentration* or *partial pressures* are equally useful and can be related by the thermodynamic equation of state. For instance, for ideal gases (approximation valid for gases at very low pressure)

$$PV = nRT \quad (7-29)$$

When applied to individual components in a constant-volume system,

$$p_i V = n_i RT \quad (7-30)$$

Using Eq. (7-5), we obtain the relationship between the volumetric concentrations and partial pressures:

$$C_i = \frac{p_i}{RT} \quad (7-31)$$

For an ideal gas the total concentration is

$$C = \frac{P}{RT} \quad (7-32)$$

For higher pressure and nonideal gases, a *compressibility factor*  $z_i$  can be used:

$$p_i V = z_i n_i RT \quad \text{and} \quad C_i = \frac{p_i}{z_i RT} \quad (7-33)$$

Other relevant equations of state can also be used for both gases and liquids. This aspect is not in the scope of this section, and the reader is referred to the relevant section of this handbook.

Other concentration units include *mole fractions* for liquid  $x_i$ :

$$x_i = \frac{n_i}{\sum n_i} = \frac{C_i}{\sum C_i} = \frac{C_i}{C} \quad (7-34)$$

and for gas  $y_i$ :

$$y_i = \frac{n_i}{\sum n_i} = \frac{C_i}{\sum C_i} = \frac{C_i}{C} = \frac{p_i}{\sum p_i} = \frac{p_i}{P} \quad (7-35)$$

The last two terms are only valid for an ideal gas.

### STOICHIOMETRIC BALANCES

**Single Reactions** Equation (7-22) shows that for a single reaction, the number of moles and concentration of all other components can be calculated from the extent of reaction  $\xi$  or the conversion based on the limiting reactant, say  $A$ ,  $X_a$ . In terms of number of moles  $n_i$ ,

$$\begin{aligned} n_a &= n_{a0} - v_a \xi = n_{a0}(1 - X_a) \\ n_b &= n_{b0} - v_b \xi = n_{b0}(1 - X_b) = n_{b0} - \frac{v_b}{v_a} n_{a0} X_a \\ &\dots \\ n_r &= n_{r0} + v_r \xi = n_{r0} - \frac{v_r}{v_a} n_{a0} X_a \\ n_s &= n_{s0} + v_s \xi = n_{s0} - \frac{v_s}{v_a} n_{a0} X_a \\ &\dots \end{aligned} \quad (7-36)$$

Similarly the number of moles of each component in terms of moles of  $A$ ,  $n_{a0}$ , is

$$\begin{aligned} n_b &= n_{b0} - \frac{v_b}{v_a} (n_{a0} - n_a) \\ &\dots \\ n_r &= n_{r0} + \frac{v_r}{v_a} (n_{a0} - n_a) \\ n_s &= n_{s0} + \frac{v_s}{v_a} (n_{a0} - n_a) \\ &\dots \end{aligned} \quad (7-37)$$

Change in number of moles by the reaction and change in temperature, pressure, and density affect the translation of stoichiometric balances from number of moles to volumetric concentrations. These relationships are different for gases and liquids. For instance, for *constant density* systems (such as many liquid-phase isothermal reactions) or for *constant temperature, constant pressure* gas reaction with no change in number of moles, Eqs. (7-36) and (7-37) can be changed to volumetric concentration  $C_i$  by dividing each equation by the constant reaction volume  $V$  (e.g., in a batch reactor) and using Eq. (7-5). For example, for the single reaction (7-4) with rate (7-5):

$$\begin{aligned} C_b &= C_{b0} - \frac{q}{p} (C_{a0} - C_a) \\ C_r &= C_{r0} + \frac{r}{p} (C_{a0} - C_a) \\ C_s &= C_{s0} + \frac{s}{p} (C_{a0} - C_a) \end{aligned} \quad (7-38)$$

$$r = k C_a^a \left[ C_{b0} - \frac{q}{p} (C_{a0} - C_a) \right]^b = k [C_{a0}(1 - X_a)]^a \left( C_{b0} - \frac{q}{p} C_{a0} X_a \right)^b \quad (7-39)$$

It is best to represent all concentrations in terms of that of the limiting reactant.

Often there is a change in total number of moles due to reaction. Taking the general reaction (7-1), in the gas phase the change in

number of moles relative to moles of component A converted,  $\delta_a$ , and the total number of moles can be calculated as follows:

$$\delta_a = \frac{v_q + v_s + \dots - v_a - v_b - \dots}{v_a}$$

$$n_a = \sum n_{i0} \quad n = \sum n_i \quad (7-40)$$

$$\frac{n}{n_0} = 1 + y_{a0} \delta_a X_a = 1 + \varepsilon_a X_a$$

$$\varepsilon_a = y_{a0} \delta_a$$

Using the ideal gas law, Eq. (7-29), the volume change depends on conversion as follows:

$$\frac{V}{V_0} = \frac{T}{T_0} \frac{P_0}{P} \frac{n}{n_0} = \frac{T}{T_0} \frac{P_0}{P} (1 + \varepsilon_a X_a) \quad (7-41)$$

Hence, for an isothermal constant-pressure ideal gas reaction system,

$$C_a = \frac{n_a}{V} = \frac{C_{a0}(1 - X_a)}{1 + \varepsilon_a X_a}$$

$$C_b = \frac{n_b}{V} = \frac{C_{b0} - \frac{v_b}{v_a} C_{a0} X_a}{1 + \varepsilon_a X_a}$$

$$\dots$$

$$C_r = \frac{n_r}{V} = \frac{C_{r0} - \frac{v_r}{v_a} C_{a0} X_a}{1 + \varepsilon_a X_a}$$

$$C_s = \frac{n_s}{V} = \frac{C_{s0} - \frac{v_s}{v_a} C_{a0} X_a}{1 + \varepsilon_a X_a}$$

$$\dots$$
(7-42)

Applying this to reaction (7-4) and rate (7-5) gives

$$r = k \left[ \frac{C_{a0}(1 - X_a)}{1 + \varepsilon_a X_a} \right]^a \left[ \frac{C_{b0} - (q/p) C_{a0} X_a}{1 + \varepsilon_a X_a} \right]^b \quad (7-43)$$

Compare this to Eq. (7-39) where there is no change in number of moles.

**Reaction Networks** The analysis for single reactions can be extended to a network of reactions by defining an extent of reaction for each reaction, or by choosing a representative reactant concentration for each reaction step. For a complex network, the number of independent extents of reaction required to calculate the concentration of all components is equal to the number of *independent reactions*, which is less than or equal to the total number of reactions in the network. To calculate the number of independent reactions, and to form a set of independent reactions and corresponding independent set of concentrations or extents of reaction, we need to construct the *stoichiometric matrix* and determine its *rank*. The stoichiometric matrix is used to derive a relationship between the concentrations and the independent extents of reaction similar to that of a single reaction.

The stoichiometric matrix is the matrix of the stoichiometric coefficients of the reaction network with negative signs for reactants and positive signs for products. For instance, the hydrodechlorination of Freon 12 ( $\text{CF}_2\text{Cl}_2$ ) can proceed with the following consecutive mechanism [Bonarowska et al., "Hydrodechlorination of  $\text{CCl}_2\text{F}_2$  (CFC-12) over Silica-Supported Palladium-Gold Catalysts," *Appl. Catal. B: Environmental*, **30**:187–193, 2001]:

The stoichiometric matrix S for this network is

$$S = \begin{pmatrix} -1 & 1 & 0 & -1 & 1 \\ 0 & -1 & 1 & -1 & 1 \end{pmatrix}$$

The first row refers to the first reaction and the second row to the second reaction. The columns (species) are in the following order: 1- $\text{CF}_2\text{Cl}_2$ , 2- $\text{CF}_2\text{ClH}$ , 3- $\text{CF}_2\text{H}_2$ , 4- $\text{H}_2$ , and 5- $\text{HCl}$ . The rank of a matrix is the largest square submatrix obtained by deleting rows and columns, whose determinant is not zero. The rank equals the number of independent reactions. This is also equivalent to stating that there are reactions in the network that are linear combinations of the independent reactions. The rank of S above is 2, since the *determinant* of the first  $2 \times 2$  submatrix is not zero (there are other  $2 \times 2$  submatrices that are not zero as well but it is sufficient to have at least one that is not zero):

$$S_1 = \begin{pmatrix} -1 & 1 \\ 0 & -1 \end{pmatrix} \quad \det(S_1) = 1 \neq 0$$

Hence the two reactions are independent. Now if we add another step, which converts Freon 12 directly into the final hydrofluorocarbon  $\text{CF}_2\text{H}_2$ :  $\text{CF}_2\text{Cl}_2 + 2\text{H}_2 \Rightarrow \text{CF}_2\text{H}_2 + 2\text{HCl}$ , then the stoichiometric matrix becomes

$$S = \begin{pmatrix} -1 & 1 & 0 & -1 & 1 \\ 0 & -1 & 1 & -1 & 1 \\ -1 & 0 & 1 & -2 & 2 \end{pmatrix}$$

Since the last reaction is a linear combination of the first two (sum), it can be easily proved that the rank remains unchanged at 2. So to conclude, the concentrations of all components in this network can be expressed in terms of two, say  $\text{H}_2$  and Freon 12, and the first two reactions form an independent reaction set. In case of more complicated networks it may be difficult to determine the independent reactions by observation alone. In this case the *Gauss-Jordan decomposition* leads to a set of independent reactions (see, e.g., Amundson, *Mathematical Methods in Chemical Engineering—Matrices and Their Application*, Prentice-Hall International, New York, 1966).

For a network of reactions the general procedure is as follows:

1. Generate the reaction network by including all known reaction steps.
2. Generate the corresponding stoichiometric matrix.
3. Calculate the rank of the stoichiometric matrix which equals the number of independent reactions and independent component concentrations required to calculate all the remaining component concentrations.
4. For relatively simple networks, observation allows selection of reactions that are independent—for more complex systems use the Gauss-Jordan elimination to reduce the network to a set of independent (nonzero rows) reactions.
5. Select the independent concentration variables and independent reactions, and use these to calculate all other concentrations and reaction rates.

## CATALYSIS

A catalyst is a material that increases the rate of both the forward and reverse reactions of a reaction step, with no net consumption or generation of catalyst by the reaction. A catalyst does not affect the reaction thermodynamics, i.e., the equilibrium composition or the heat of reaction. It does, however, affect the temperature sensitivity of the reaction rate by lowering the activation energy or the energy barrier on the reaction pathway from reactants to products. This allows the reaction to occur faster than the corresponding uncatalyzed reaction at a given temperature. Alternatively, catalytic reactions can proceed at lower temperatures than the corresponding noncatalytic reactions. For a network of reactions, the catalyst is often used to speed up desired reactions and/or to slow down undesired reactions for improved selectivity. On the basis of catalysis, reactions can be further classified into

1. Noncatalytic reactions, e.g., free-radical gas-phase reactions such as combustion of hydrocarbons.

## 7-10 REACTION KINETICS

2. Homogeneous catalytic reactions with the catalyst being dissolved in the same phase as the reactants and products in a homogeneous reaction medium. Here the catalyst is uniformly distributed throughout the system, e.g., the hydroformylation of olefins in the presence of dissolved Co or Rh carbonyls.

3. Heterogeneous catalytic reactions, with the catalyst, for instance, being a solid in contact with reactants and products in a gas-solid, gas-liquid-solid, or a liquid-solid reaction system. Here the catalyst is not uniformly distributed, and the reaction occurring on the catalyst surface requires, for instance, adsorption of reactants and desorption of products from the solid surface, e.g., the catalytic cracking of gasoil to gasoline and lighter hydrocarbons.

Table 7-1 illustrates the enhancement of the reaction rates by the catalyst—this enhancement can be of many orders of magnitude.

**TABLE 7-1 The Rate of Enhancement of Some Reactions in the Presence of a Catalyst**

| Reaction  | Catalyst     | Rate enhancement   | Temperature, K |
|---|--------------|--------------------|----------------|
| Ortho $H_2 \Rightarrow$ para $H_2$                | Pt (solid)   | $10^{40}$          | 300            |

## IDEAL REACTORS

Reactions occur in reactors, and in addition to the intrinsic kinetics, observed reaction rates depend on the reactor type, scale, geometry, mode of operation, and operating conditions. Similarly, understanding of the reactor system used in the kinetic experiments is required to determine the reaction mechanism and intrinsic kinetics. In this section we address the effect of reactor type on observed rates. In Sec. 19 the effect of reactor type on performance (rates, selectivity, yield) is discussed in greater detail.

Material, energy, and momentum balances are essential to fully describe the performance of reactors, and often simplifying assumptions and phenomenological assumptions are needed especially for energy and momentum terms, as indicated in greater detail in Sec. 19

(see also Bird, Stewart, and Lightfoot, *Transport Phenomena*, 2d ed., John Wiley & Sons, New York, 2002). Ideal reactors allow us to simplify the energy, momentum, and material balances, thus focusing the analysis on intrinsic kinetics. A useful classification of ideal reactor types is in terms of their concentration distributions versus reaction time and space. Three types of ideal reactors are considered in this section:

1. Ideal *batch reactors (BRs)* including *semibatch reactors (SBRs)*
2. Ideal *continuously stirred tank reactor (CSTR)*, including single and multiple stages
3. *Plug flow reactor (PFR)* with and without *recycle*

Figure 7-1 shows these types of ideal reactors. Other types of ideal and nonideal reactors are treated in detail in Sec. 19.

**FIG. 7-1** Types of ideal reactors: (a) Batch or semibatch. (b) CSTR or series of CSTRs. (c) Plug flow.

The general form of a balance equation is

$$\text{Input} + \text{sources} - \text{outputs} = \text{accumulation} \quad (7-44)$$

### IDEAL BATCH REACTOR

**Batch Reactor (BR)** Ideal batch reactors (Fig. 7-1a) are tanks provided with agitation for uniform composition and temperature at all times. An ideal batch reactor can be operated under isothermal conditions (constant temperature), temperature-programmed mode (by controlling cooling rate according to a protocol), or adiabatic mode with no heat crossing the reactor boundaries). In adiabatic mode the temperature is increasing, decreasing, or constant as the reaction proceeds for exothermic, endothermic, and thermally neutral reactions, respectively. In the ideal batch reactor, all the reactants are loaded into the reactor and well mixed by agitation before the conditions for reaction initiation (temperature and pressure) are reached; as the reaction proceeds, the concentration varies with time, but at any one time it is uniform throughout due to agitation.

Laboratory batch reactors can be single-phase (e.g., gas or liquid), multiphase (e.g., gas-liquid or gas-liquid-solid), and catalytic or non-catalytic. In this section we limit the discussion to operation at isothermal conditions. This eliminates the need to consider energy, and due to the uniform composition the component material balances are simple ordinary differential equations with time as the independent variable.

An ideal isothermal single-phase batch reactor in which a general reaction network takes place has the following general material balance equation:

$$\frac{dn_i}{dt} = V \sum_j \nu_{ij} r_j \quad n_i = n_{i0} \quad \text{at } t = 0 \quad (7-45)$$

The left-hand side is the accumulation term in moles per second of component  $i$ , and the right-hand side is the source term due to chemical reaction also in moles per second, which includes all reactions  $j$  that consume or produce component  $i$ , and the corresponding stoichiometric coefficients are represented in matrix form as  $\nu_{ij}$  with a positive sign for products and a negative sign for reactants. This molar

balance is valid for each component since we can multiply each side of the equation by the component molecular weight to obtain the true mass balance equation. In terms of conversion, Eq. (7-45) can be rewritten as

$$\frac{n_{i0} dX_i}{dt} = -V \sum_j \nu_{ij} r_j \quad n_i = n_{i0} \quad \text{at } t = 0 \quad (7-46)$$

and we can integrate this equation to get the *batch reaction time* or *batch residence time*  $\tau_{BR}$  required to obtain a conversion  $X_i$ , starting with initial conversion  $X_{i0}$  and ending with final conversion  $X_{if}$ :

$$\tau_{BR} = -n_{i0} \int_{X_{i0}}^{X_{if}} \frac{dX_i}{V \sum_j \nu_{ij} r_j} \quad (7-47)$$

To integrate we need to represent all reaction rates  $r_j$  in terms of the conversion  $X_i$ . For a single reaction this is straightforward [see, e.g., Eq. (7-43)]. However, for a network of reactions, integration of a system of often nonlinear differential equations is required using implicit or semi-implicit integration. For references please see the relevant section of this handbook or any textbook on ordinary differential equations.

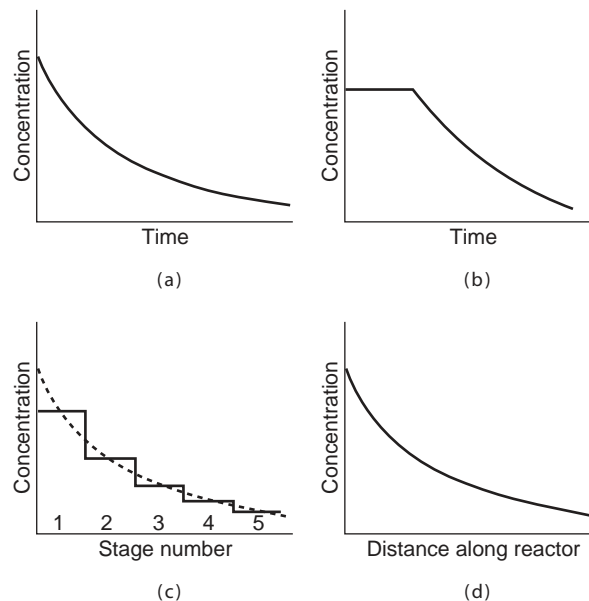

A special case of batch reactors is constant-volume or constant-density operation typical of liquid-phase reactions, with volume invariant with time:

$$\frac{dC_i}{dt} = \sum_j \nu_{ij} r_j \quad C_i = C_{i0} \quad \text{at } t = 0 \quad (7-48)$$

A typical concentration profile versus time for a reactant is shown in Fig. 7-2a. Integration of Eq. (7-48) gives the batch residence time

$$\tau_{BR} = \int_{C_{i0}}^{C_{if}} \frac{dC_i}{\sum_j \nu_{ij} r_j} \quad (7-49)$$

For instance, for a single reaction, Eq. (7-43) can be used to describe the reaction rate  $r_i$  in terms of one reactant concentration. For reaction networks integration of a system of ordinary differential equations is required.

**FIG. 7-2** Concentration profiles in batch and continuous flow: (a) Batch time profile. (b) Semibatch time profile. (c) Five-stage CSTRs distance profile. (d) Tubular flow distance profile.

## 7-12 REACTION KINETICS

**Semibatch Reactor (SBR)** In semibatch operation, a gas of limited solubility or a liquid reactant may be fed in gradually as it is used up. An ideal isothermal single-phase semibatch reactor in which a general reaction network takes place has the following general material balance equation:

$$\frac{dn_i}{dt} = N_{i0} + V \sum v_{ij} r_j \quad n_i = n_{i0} \quad \text{at } t = 0$$

$$N_{i0} = N_{i0}(t) \quad \text{for } t_{s0i} \leq t \leq t_{s1i} \quad (7-50)$$

The first term on the right-hand side of Eq. (7-50) is the molar feed rate of the components, which can be different for each component, hence the subscript  $i$ , and can vary with time. A typical concentration profile versus time for a reactant whose concentration is kept constant initially by controlling the feed rate is shown in Fig. 7-2b. Knowledge of the reaction kinetics allows these ordinary differential equations to be integrated to obtain the reactor composition versus time.

### IDEAL CONTINUOUS STIRRED TANK REACTOR (CSTR)

In an ideal continuous stirred tank reactor, composition and temperature are uniform throughout just as in the ideal batch reactor. But this reactor also has a continuous feed of reactants and a continuous withdrawal of products and unconverted reactants, and the effluent composition and temperature are the same as those in the tank (Fig. 7-1b). A CSTR can be operated under transient conditions (due to variation in feed composition, temperature, cooling rate, etc., with time), or it can be operated under steady-state conditions. In this section we limit the discussion to isothermal conditions. This eliminates the need to consider energy balance equations, and due to the uniform composition the component material balances are simple ordinary differential equations with time as the independent variable:

$$\frac{dn_i}{dt} = N_{i0} - N_i + V \sum v_{ij} r_j \quad n_i = n_{i0} \quad \text{at } t = 0 \quad (7-51)$$

At steady state the differential equations simplify to algebraic equations as indicated below:

$$V = - \frac{N_{i0} - N_i}{\sum v_{ij} r_j} \quad (7-52)$$

Equation (7-52) can be expressed in terms of volumetric concentration or in terms of conversions just as we did with the batch reactor. An *apparent residence time* based on feed conditions can be defined for a single-phase CSTR as follows:

$$\tau_{\text{CSTR}} = \frac{V}{q_0} \quad N_{i0} = q_0 C_{i0} \quad N_i = q C_i \quad (7-53)$$

In Eq. (7-53) the feed and effluent molar rates  $N_{i0}$  and  $N_i$  are expressed in terms of volumetric flow rates  $q_0$  and  $q$  (inlet and outlet, respectively) and concentrations. Thus Eq. (7-52) can be rewritten as

$$\tau_{\text{CSTR}} = \frac{C_{i0} - (q/q_0)C_i}{\sum v_{ij} r_j} \quad (7-54)$$

Equation (7-54) allows calculation of the residence time required to achieve a given conversion or effluent composition. In the case of a network of reactions, knowing the reaction rates as a function of volumetric concentrations allows solution of the set of often nonlinear algebraic material balance equations using an implicit solver such as the multi variable Newton-Raphson method to determine the CSTR effluent concentration as a function of the residence time. As for batch reactors, for a single reaction all compositions can be expressed in terms of a component conversion or volumetric concentration, and Eq. (7-54) then becomes a single nonlinear algebraic equation solved by the Newton-Raphson method (for more details on this method see the relevant section in this handbook).

A special case of Eq. (7-54) is a constant-density system (e.g., a liquid-phase reaction), with the true average residence time  $\tau_{\text{CSTR}}$

$$\tau_{\text{CSTR}} = \frac{C_{i0} - C_i}{\sum v_{ij} r_j} \quad q = q_0 \quad (7-55)$$

When a number of such CSTRs are employed in series, the concentration profile is step-shaped if the abscissa is the total residence time or the stage number as indicated by a typical reactant concentration profile in Fig. 7-2c.

### PLUG FLOW REACTOR (PFR)

In a *plug flow reactor* all portions of the feed stream move with the same radially uniform velocity along parallel streamlines and therefore have the same residence time; that is, there is no mixing in the axial direction but complete mixing radially (Fig. 7-1c). As the reaction proceeds, the concentration falls off with distance. A PFR can be operated under either transient conditions or steady-state conditions. In this section we limit the discussion to steady-state conditions. This eliminates the need to consider partial differential equations in time and space. We further limit the discussion to isothermal operation, which together with the defined plug flow also eliminates the need for energy and momentum balance equations. Due to the radially uniform composition, the component material balances are simple ordinary differential equations with axial distance from inlet as the independent variable. An isothermal single-phase steady-state PFR in which a general reaction network takes place has the following general material balance equation:

$$\frac{dN_i}{dV} = \sum v_{ij} r_j \quad N_i = N_{i0} \quad \text{at } V = 0 \quad (7-56)$$

Note the similarity between the ideal batch and the plug flow reactors, Eqs. (7-45) and (7-56), respectively. In terms of conversion, Eq. (7-56) can be written as

$$N_{i0} \frac{dX_i}{dV} = - \sum v_{ij} r_j \quad (7-57)$$

Equation (7-57) can be integrated to calculate the reactor volume required to achieve a given conversion  $X_i$ :

$$V = -N_{i0} \int_{X_{i0}}^{X_{if}} \frac{dX_i}{\sum v_{ij} r_j} \quad (7-58)$$

An *apparent residence time* based on feed conditions can be defined for a single-phase PFR as follows:

$$\tau_{\text{PFR}} = \frac{V}{q_0} \quad (7-59)$$

Equation (7-58) becomes

$$\tau_{\text{PFR}} = -C_{i0} \int_{X_{i0}}^{X_{if}} \frac{dX_i}{\sum v_{ij} r_j} \quad (7-60)$$

Equation (7-60) is identical to that of the ideal batch reactor, Eq. (7-47), and the two reactor systems can be modeled in identical fashion.

For a constant-density system with no change in number of moles, with the true residence time  $\tau_{\text{PFR}}$ :

$$\tau_{\text{PFR}} = \int_{C_{i0}}^{C_{if}} \frac{dC_i}{\sum v_{ij} r_j} \quad (7-61)$$

This is identical to the corresponding ideal batch reactor, Eq. (7-49).

**Ideal Recycle Reactor** All reactor modes can sometimes be advantageously operated with recycling part of the product or intermediate streams. Heated or cooled recycle streams serve to moderate undesirable temperature gradients, and they can be processed for changes in composition such as separating products to remove equilibrium limitations, before being returned. Say the recycle flow rate in

**TABLE 7-2 Consecutive and Parallel First-Order Reactions in an Isothermal Constant-Volume Ideal Batch or Plug Flow Reactor.**

The independent variable  $t$  is either the batch time or the plug flow residence time.

| Reaction network                               | Material balances                     | Concentration profiles   |
|--|---------------------------------------|--|
| $A \xrightarrow{1} B \xrightarrow{2} C$        | $\frac{dC_a}{dt} = -k_1 C_a$          | $C_a = C_{a0} e^{-k_1 t}$  |
|  | $\frac{dC_b}{dt} = k_1 C_a - k_2 C_b$ | $C_b = C_{b0} e^{-k_2 t} + \frac{k_1 C_{a0}}{k_2 - k_1} (e^{-k_1 t} - e^{-k_2 t})$ |
|  | $\frac{dC_c}{dt} = k_2 C_b$           | $C_c = C_{a0} + C_{b0} + C_{c0} - C_a - C_b$                                       |
| $A \xrightarrow{1} B$<br>$A \xrightarrow{2} C$ | $\frac{dC_a}{dt} = -(k_1 + k_2) C_a$  | $C_a = C_{a0} e^{-(k_1 + k_2)t}$   |
|  | $\frac{dC_b}{dt} = k_1 C_a$           | $C_b = C_{b0} + \frac{k_1 C_{a0}}{k_2 + k_1} (1 - e^{-(k_1 + k_2)t})$              |
|  | $\frac{dC_c}{dt} = k_2 C_a$           | $C_c = C_{a0} + C_{b0} + C_{c0} - C_a - C_b$                                       |

a PFR is  $q_R$  and the fresh feed rate is  $q_0$ . With a fresh feed concentration of  $C_0$  and a product concentration of  $C_2$ , the composite reactor feed concentration  $C_1$  and the recycle ratio  $R$  are

$$C_1 = \frac{C_0 + RC_2}{1 + R} \quad R = \frac{q_R}{q_0} \quad (7-62)$$

The change in concentration across the reactor becomes

$$\Delta C = C_1 - C_2 = \frac{C_2 - C_0}{1 + R} \quad (7-63)$$

Accordingly, the change in concentration (or in temperature) across the reactor can be made as small as desired by increasing the recycle ratio. Eventually, the reactor can become a well-mixed unit with essentially constant concentration and temperature, while substantial differences in composition will concurrently arise between the fresh feed inlet and the product withdrawal outlet, similar to a CSTR. Such an operation is useful for obtaining experimental data for analysis of rate

equations. In the simplest case, where the product is recycled without change in composition, the flow reactor equation at constant density is

$$\tau_{PFR} = (1 + R) \int_{C_{i0}}^{C_{if}} \frac{dC_i}{\sum v_j f_j} \quad (7-64)$$

Hence, recycling increases the residence time or reactor size required to achieve a given conversion, since  $1 + R > 1$ .

**EXAMPLES FOR SOME SIMPLE REACTIONS**

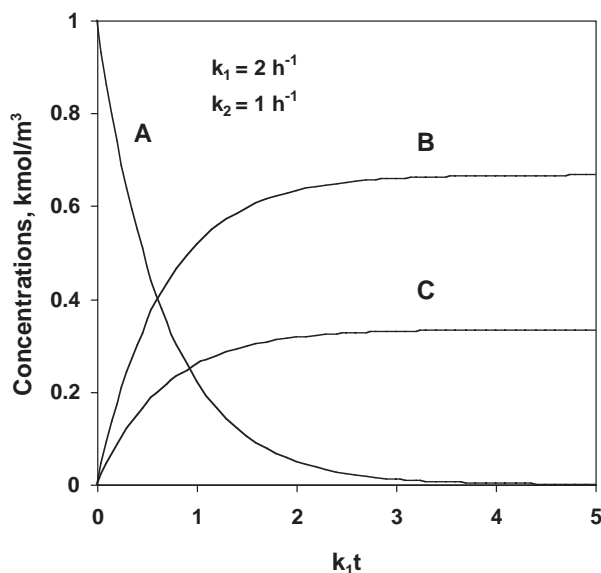

Table 7-2 and Figs. 7-3 and 7-4 show the analytical solution of the integrals for two simple first-order reaction systems in an isothermal constant-volume batch reactor or plug flow reactor. Table 7-3 shows the analytical solution for the same reaction systems in an isothermal constant-density CSTR.

Section 19 provides discussion about advantages and disadvantages of CSTRs versus PFR and BR for various reaction systems.

## KINETICS OF COMPLEX HOMOGENEOUS REACTIONS

Global or complex reactions are not usually well represented by mass action kinetics because the rate results from the combined effect of several simultaneous elementary reactions (each subject to mass action kinetics) that underlie the global reaction. The elementary steps include short-lived and unstable intermediate components such as free radicals, ions, molecules, transition complexes, etc.

The reason many global reactions between stable reactants and products have complex mechanisms is that these unstable intermediates have to be produced in order for the reaction to proceed at reasonable rates. Often simplifying assumptions lead to closed-form kinetic rate expressions even for very complex global reactions, but care must be taken when using these since the simplifying assumptions are valid over limited ranges of compositions, temperature, and pressure. These assumptions can fail completely—in that case the full elementary reaction network has to be considered, and no closed-form kinetics can be derived to represent the complex system as a global reaction.

Typical simplifying assumptions include these:

- *Pseudo-steady-state* approximation for the unstable intermediate; i.e., the concentration of these does not change during reaction
- Equilibrium for certain fast reversible reactions and completion of very fast irreversible steps
- *Rate-determining step(s)*; i.e., the global reaction rate is determined by the rate(s) of the slowest step(s) in the reaction network composing the overall or global reaction

These simplifying assumptions allow elimination of some reaction steps, and representation of free radical and short-lived intermediates concentrations in terms of the concentration of the stable measurable components, resulting in complex non-mass action rate expressions.

Complex reactions can proceed through *chain* or *nonchain* mechanisms. In a *chain reaction*, the active unstable components are produced in an *initiation* step and are repeatedly regenerated through *propagation* steps, and only a small fraction of these are converted to stable components through a *termination* step. Free radicals are examples of such unstable components frequently encountered in chain reactions: free radicals are molecular fragments having one or more unpaired electrons, are usually short-lived (milliseconds), and are highly reactive. They are detectable spectroscopically, and some have been isolated. They occur as initiators and intermediates in such

basic phenomena as oxidation, combustion, photolysis, and polymerization. Several examples of free radical mechanisms possessing non-integral power law or hyperbolic rate equations are cited below. In a *nonchain reaction*, the unstable intermediate, such as an *activated complex* or *transition state complex*, reacts further to produce the products, and it is not regenerated through propagation but is continually made from reactants in stoichiometric quantities.

### CHAIN REACTIONS

**Phosgene Synthesis** The global reaction  $\text{CO} + \text{Cl}_2 \Rightarrow \text{COCl}_2$  proceeds through the following free radical mechanism:

Assuming the first two reactions are in equilibrium, expressions are found for the concentrations of the free radicals  $\text{Cl}\cdot$  and  $\text{COCl}\cdot$  in terms of the species  $\text{CO}$ ,  $\text{Cl}_2$ , and  $\text{COCl}_2$ , and when these are substituted into the mass action rate expression of the third reaction, the rate becomes

$$r_{\text{COCl}_2} = k(\text{CO})(\text{Cl}_2)^{3/2} \quad (7-65)$$

**Ozone Conversion to Oxygen in Presence of Chlorine** The global reaction  $2\text{O}_3 \xrightarrow{\text{Cl}_2} 3\text{O}_2$  in the presence of  $\text{Cl}_2$  proceeds through the following sequence:

The chain carriers  $\text{ClO}\bullet$ ,  $\text{ClO}_2\bullet$ , and  $\text{ClO}_3\bullet$  are assumed to attain pseudo-steady state. Then,

$$r_{\text{O}_3} = k(\text{Cl}_2)^{1/2}(\text{O}_3)^{3/2} \quad (7-66)$$

**Hydrogen Bromide Synthesis** The global reaction  $\text{H}_2 + \text{Br}_2 \Rightarrow 2\text{HBr}$  proceeds through the following chain of reactions:

Assuming pseudo-steady state for the concentrations of the free radicals  $\text{H}\bullet$  and  $\text{Br}\bullet$ , the global rate equation becomes

$$r_{\text{HBr}} = \frac{k_1(\text{H}_2)(\text{Br}_2)^{1/2}}{k_2 + \text{HBr}/\text{Br}_2} \quad (7-67)$$

**Chain Polymerization** For free radical polymerization, the following generic mechanism can be postulated:

Initiation:

Propagation:

Termination:

The rates of formation of the free radicals  $R\bullet$  and  $M\bullet$  reach pseudo-steady states, resulting in the following polymerization rate:

$$r_p = k_p(M)(M^*) = k_p \left( \frac{k_i}{k_t} \right)^{1/2} (M)(I)^{1/2} \quad (7-68)$$

## NONCHAIN REACTIONS

Nonchain reactions proceed through an active intermediate to the products. Many homogeneous nonchain reactions are also homogeneously catalyzed reactions, discussed below.

## HOMOGENEOUS CATALYSIS

Homogeneous catalysts proceed through an activated or transition state complex between reactant(s) and catalysts, which decomposes into products. Homogeneous catalysts are dissolved in the homogeneous reaction mixture and include among others acids/bases, metal salts, radical initiators, solvents, and enzymes.

**Acid-Catalyzed Isomerization of Butene-1** Butene-1 isomerizes to butene-2 in the presence of an acid according to the global reaction

Even though this appears to be a monomolecular reaction, it is not, as it proceeds through the following mechanism:

Assuming reaction 1 is in equilibrium, the reaction rate is

$$r = k_2 K_1 [\text{H}^+] [\text{CH}_3\text{CH}_2\text{HC}=\text{CH}_2] \quad (7-69)$$

**Enzyme Kinetics** Enzymes are homogeneous catalysts for cellular and enzymatic reactions. The enzyme  $E$  and the reactant  $S$  are

FIG. 7-5 Product concentration profile for the autocatalytic reaction  $A + P \Rightarrow 2P$  with rate  $r = kC_a C_p$ .

## 7-16 REACTION KINETICS

assumed to form a complex  $ES$  that then dissociates into product  $P$  and releases the enzyme:

Assuming equilibrium for the first step results in the following rate, developed by Michaelis and Menten [*Biochem. Zeit.*, **49**:333 (1913)] and named Michaelis-Menten kinetics,

$$r_p = -r_s = \frac{k(S)}{K_m + (S)} \quad (7-70)$$

Here  $K_m$  is the inverse of the equilibrium constant for the first reaction.

### AUTOCATALYSIS

In an autocatalytic reaction, a reactant reacts with a product to make more product. For the reaction to proceed, therefore, product must be present

initially in a batch or in the feed of a continuous reactor. Examples are cell growth in fermentation and combustion of fuels. For instance, the irreversible elementary reaction  $A + P \Rightarrow 2P$  has the mass action kinetics

$$r = kC_a C_p \quad (7-71)$$

For an ideal batch reactor (see, e.g., Steinfeld, Francisco, and Hase, *Chemical Kinetics and Dynamics*, Prentice-Hall, 1989):

$$\frac{dC_a}{dt} = -kC_a C_p \quad \frac{dC_p}{dt} = kC_a C_p \quad C_a + C_p = C_{a0} + C_{p0} \quad (7-72)$$

Integration results in the following concentration profile:

$$C_p = \frac{C_{a0} + C_{p0}}{1 + (C_{a0}/C_{p0})e^{-k(C_{a0} + C_{p0})t}} \quad C_a = C_{a0} + C_{p0} - C_p \quad (7-73)$$

Figure 7-5 illustrates the dimensionless concentration profile for the reactant  $A$  and product  $P$ ,  $C_i/(C_{a0} + C_{p0})$ , for  $C_{a0}/C_{p0} = 2$ , indicative of a maximum rate at the inflexion point (maximum in slope of the concentration-time curve), typical to autocatalytic reactions.

## INTRINSIC KINETICS FOR FLUID-SOLID CATALYTIC REACTIONS

There are a large number of fluid-solid catalytic reactions, mostly gas-solid, including catalytic cracking, oxidation of polluting gases in automotive and power generation catalytic converters, partial oxidation synthesis reactions such as HCN synthesis, chemical vapor deposition, etc. (see, e.g., Sec. 19 for more examples). Examples of solid catalysts include, among others, supported metals, transition metal oxides and sulfides, solid acids and bases, and immobilized homogeneous catalysts and enzymes. Solid catalysts can be a fine powder (suspended in a liquid or fluidized by a flowing gas), cylindrical, spherical, and more-complex-shaped particles (in a packed bed), a thin layer of active components (on the walls of a monolith or a foam) and gauzes. The solid catalyst can be porous with active component distributed throughout the particle volume, or nonporous with active component present on the exposed catalyst external surface alone.

The analysis of Langmuir [*J. Am. Chem. Soc.* **40**:1361 (1918)] and Hinshelwood (*Kinetics of Chemical Change*, Oxford, 1940) form the basis for the simplified treatment of kinetics on heterogeneous catalysts. For a solid catalyzed reaction between gas phase reactants  $A$  and  $B$ , the postulated mechanism consists of the following steps in series:

1. The reactants from the gas adsorb to bond to active sites on the catalyst surface as molecules or dissociated atoms. The rate of adsorption is proportional to the partial pressure of reactants and to the fraction of uncovered surface sites  $\vartheta_v$ . More than one type of active site can be present. The adsorption isotherms such as the Langmuir isotherm relate the partial pressure of an adsorbed species to its surface coverage, and the form of this relationship is indicative of the type of adsorption process taking place (see, for more details, Masel, *Chemical Kinetics and Catalysis*, Wiley, 2001).

2. The adsorbed species react on the surface to form adsorbed products. The rate of reaction between adsorbed species is proportional to their adsorbed concentrations on the surface.

3. The adsorbed products desorb into the gas. The rate of desorption of species  $A$  is proportional to the fraction of the surface covered by  $A$ ,  $\vartheta_a$ .

For instance, for the simple irreversible reaction  $A + B \Rightarrow C + D$ , the postulated mechanism is

$A\sigma$ ,  $B\sigma$ ,  $C\sigma$ , and  $D\sigma$  above are adsorbed species on the catalyst surface, and  $\sigma$  is an available active site. We will consider a variety of possible scenarios for this simple solid-catalyzed system. Note that the intrinsic specific reaction rate for such systems is often expressed on a unit mass catalyst basis ( $r_m$ ) instead of unit reaction volume basis ( $r_v$ ), and the latter is related to the former through the catalyst loading (mass catalyst/reaction volume) or bed density:

$$r_v = \frac{r_m M_{\text{cat}}}{V} = r_m \rho_B \quad (7-75)$$

### ADSORPTION EQUILIBRIUM

Assuming equilibrium for all adsorption steps (e.g., the surface reaction is rate-limiting), the net rates of adsorption of reactants and product are all zero.

$$r_i = k_i p_i \vartheta_v - k_{-i} \vartheta_i \Rightarrow 0 \quad i = a, b, c, d \quad (7-76)$$

A material balance on all sites yields

$$\vartheta_v = 1 - \vartheta_a - \vartheta_b - \vartheta_c - \vartheta_d \quad (7-77)$$

and solving for the surface coverages gives

$$\begin{aligned} \vartheta_a &= \left( \frac{k_a}{k_a - a} \right) p_a \vartheta_v = K_a p_a \vartheta_v & \vartheta_b &= \left( \frac{k_b}{k_b - b} \right) p_b \vartheta_v = K_b p_b \vartheta_v \\ \vartheta_c &= \left( \frac{k_c}{k_c - c} \right) p_c \vartheta_v = K_c p_c \vartheta_v & \vartheta_d &= \left( \frac{k_d}{k_d - d} \right) p_d \vartheta_v = K_d p_d \vartheta_v \end{aligned} \quad (7-78)$$

The fraction of surface not covered is

$$\vartheta_v = \frac{1}{1 + K_a p_a + K_b p_b + K_c p_c + K_d p_d} \quad (7-79)$$

In the denominator, terms may be added for adsorbed inerts (e.g.,  $K_i p_i$ ) that may be present, and analogous expressions for the other participants. The rate of reaction or the rate-determining step is that between adsorbed reactant species:

$$r = k p_a p_b \vartheta_v^2 = \frac{k p_a p_b}{(1 + K_a p_a + K_b p_b + K_c p_c + K_d p_d)^2} \quad (7-80)$$

**DISSOCIATION**

A diatomic molecule  $A_2$  may adsorb dissociatively as atoms

with the result

$$\theta_a = \frac{\sqrt{K_a p_a}}{1 + \sqrt{K_a p_a} + K_b p_b + \dots} = \sqrt{K_a p_a} \theta_v \tag{7-82}$$

and the rate-determining step and its rate are

**DIFFERENT SITES**

When  $A$  and  $B$  adsorb on chemically different sites  $\sigma_1$  and  $\sigma_2$ , the rate of the reaction, with surface reaction controlling,

is

$$r = \frac{k p_a p_b}{(1 + K_a p_a)(1 + K_b p_b)} \tag{7-85}$$

**CHANGE IN NUMBER OF MOLES**

When the numbers of moles of product is larger than that of the reactants, extra sites are required:

and the rate is

$$r = k \left( \theta_a \theta_v - \frac{\theta_m \theta_n}{K} \right) = \left( p_a - \frac{p_m p_n}{K} \right) \theta_v^2 = \frac{k(p_a - p_m p_n / K)}{(1 + K_a p_a + K_m p_m + K_n p_n)^2} \tag{7-88}$$

**REACTANT IN THE GAS PHASE**

When  $A$  in the gas phase reacts directly with adsorbed  $B$ :

$$r = k p_a \theta_b = k p_a p_b \theta_v = \frac{k p_a p_b}{1 + \sum K_i p_i} \tag{7-89}$$

This mechanism is called the *Ely-Rideal kinetics*.

**CHEMICAL EQUILIBRIUM IN GAS PHASE**

When  $A$  is not in adsorptive equilibrium but it is in chemical equilibrium in the gas phase according to

this expression is substituted for  $p_a$  wherever it appears in the rate equation. If the rate-determining step is the surface reaction between adsorbed species, then

$$r = k p_a p_b \theta_v^2 = \frac{k p_m p_n / K_e}{1 + K_a(p_m p_n / K_e p_b) + K_b p_b + K_m p_m + K_n p_n} \tag{7-91}$$

Table 7-4 summarizes some examples of reactions where all substances are in adsorptive equilibrium and the surface reaction controls the rate. In Table 7-5, substance  $A$  is not in adsorptive equilibrium, and its adsorption rate is controlling. Details of the derivations of these and some other equations are presented by Yang and Hougen [*Chem. Eng.*

**TABLE 7-4 Surface-Reaction Controlling.**

Adsorptive equilibrium maintained for all participants.

### NO RATE-CONTROLLING STEP

All the relations developed above assume that only one step is controlling. In a reaction system, changing the operating conditions may shift the control from one step to another. It is therefore also obvious that at certain conditions there is no single step controlling. In that case all the reactions and their respective rates have to be considered, and the adsorbed species cannot be eliminated from the rate expressions to obtain a single closed-form kinetic rate.

### LIQUID-SOLID CATALYTIC REACTIONS

An analogous treatment for liquid-solid catalysis can be derived, with partial pressures replaced by liquid volumetric concentrations. Otherwise all the analyses hold.

### BIOCATALYSIS

Biochemical reactions such as *aerobic* and *anaerobic fermentations* occur in the presence of living organisms or *cells*, such as bacteria, algae, and yeast. These reactions can be considered as *biocatalyzed* by the organism. Thus in a typical bioreactor a *substrate* (such as glucose) is fed into the *fermenter* or *bioreactor* in the presence of an initial amount of cells. The desired product can be the cells themselves or a secreted chemical called a *metabolite*. In either case the cells multiply in the presence of the substrate, and the rate of production of cells is proportional to the concentration of the cells—hence this process is autocatalytic. In a batch reactor with ample

supply of substrate, this results in *exponential growth* of the culture. A typical cell or biomass growth rate function, called the *Monod kinetics*, is identical in form to the Michaelis-Menten enzyme kinetics in Eq. (7-70):

$$\mu = \frac{\mu_{\max} C_s}{K_s + C_s} \quad (7-92)$$

In Eq. (7-92)  $\mu$  is the *specific growth rate* of the culture. It is measured in units of reciprocal time ( $\text{h}^{-1}$ ). Growth rate  $\mu$  is related to the *volumetric growth rate*  $r_x$  of the culture:  $r_x = C_A \mu$ . This means that the true unit of  $\mu$  is, e.g., (g biomass formed/h)/(g biomass present), where *g biomass* is the *dry-weight* (DW) of the biomass, obtained after evaporation of the water content of the cell (which constitutes about 80 percent of the *wet biomass weight*). Similarly  $C_s$  has the unit, e.g., (g DW)/(L medium volume). The variable  $C_s$  in Eq. (7-92) is the concentration of the *limiting substrate* in the medium (g/L). There are many substrates (including micronutrients) in the medium, but there is usually just one that determines the specific growth rate. This substrate is often a sugar (most likely glucose) but it could also be a metal ion ( $\text{Mg}^{2+}$  etc.), or  $\text{PO}_4^{3-}$ ,  $\text{NH}_4^+$ , . . . , or perhaps a hormone. The limiting substrate may easily change during a fermentation, and then the rate expression will change.

The two parameters in Eq. (7-92) are the *maximum specific growth rate*  $\mu_{\max}$  ( $\text{h}^{-1}$ ) and the *saturation constant*  $K_s$  (g substrate/L). The value of  $K_s$  is obtained as the substrate concentration at which  $\mu = 1/2 \mu_{\max}$  (see Fig. 7-6). The form of Eq. (7-92) is entirely empirical, but it incorporates two important features: (1) At high substrate concentration the whole cell machinery is involved in cell synthesis, and the specific growth rate reaches a maximum  $\mu_{\max}$ ; (2) at low substrate concentration formation of biomass is a first-order rate process (as in any other chemical reaction) and  $\mu \rightarrow (\mu_{\max}/K_s)C_s$ . Note that for many commonly used microorganisms  $K_s$  is much

FIG. 7-6 The effect of substrate concentration on specific growth rate.

smaller than the substrate concentration  $C_s$ . Thus in batch cultivations  $K_s$  is several orders of magnitude smaller than  $C_s$  until the very end of the batch, and this is what gives the well-known *exponential growth* [see Eq. (7-93)]. Equation (7-93) applies for batch cultures after an initial *lag phase* when cell machinery is synthesized. Typical values for  $K_s$  are 150 mg/L (*Saccharomyces cerevisiae*), 5 to 10 mg/L (lactic bacteria and *E. coli*), and less than 1 mg/L (filamentous fungi).

$$\frac{dC_x}{dt} = \mu C_x \quad C_x = C_{x0} e^{\mu t} \quad (7-93)$$

Equation (7-93) may have to be modified by subtraction of a *death-rate* term  $\mu_d C_x$ .  $\mu_d$  may well increase during the batch fermentation in which case the net growth rate of (viable) cells eventually becomes negative, and the concentration of (viable) cells will start to decrease.

## FLUID-SOLID REACTIONS WITH MASS AND HEAT TRANSFER

### GAS-SOLID CATALYTIC REACTIONS

The Langmuir-Hinshelwood mechanism of adsorption/reaction described above allowed us to relate the gas concentrations and partial pressures in the vicinity of the catalyst surface to the adsorbed species concentration at the active sites, which in turn determined the surface reaction rates. In practice, two additional mass-transfer processes may need to be considered:

1. Diffusion to and from the bulk gas to the external catalyst surface, represented as an external mass-transfer process across a film or boundary layer concentration gradient. For nonporous catalyst this is the only mass-transfer step.
2. Diffusion to and from the catalyst external surface through pores in a porous catalyst particle to active sites inside the catalyst particle where the adsorption and reaction occur, represented as intraparticle diffusion and modeled as a diffusion-reaction process.

**External Mass Transfer** In a reactor, the solid catalyst is deposited on the surface of narrow tubes (such as monolith or foams), is packed as particles in a tube, or is suspended in slurry or in a fluidized bed as fine particles. For these systems, the bulk concentration of the gas phase approaches that on the catalyst surface if the mass-transfer rate from bulk to surface is substantially larger than the reaction rates on the surface. This, however, is often not the case. The mechanism of mass transfer and reaction on the external catalyst surface includes the following consecutive steps:

1. Mass transfer of gas reactants from the bulk gas to the solid catalyst surface, also called external mass transfer
2. Adsorption, reaction on the surface, and desorption of products, e.g., Langmuir-Hinshelwood kinetics
3. Mass transfer of products from the catalyst surface to the bulk gas

At steady state all these rates are equal.

For example, for a first-order irreversible reaction  $A \Rightarrow B$ , the rate of mass transfer equals the rate of intrinsic reaction:

$$k_s a_s (C_a - C_{as}) = k C_{as} \quad (7-94)$$

Here  $a_s$  is, for instance, the external particle surface area/volume of reactor. Eliminating the surface concentration  $C_{as}$  in terms of the observable bulk gas concentration  $C_a$  yields the overall specific rate of consumption of A:

$$r_{\text{obs}} = k C_a = \frac{C_a}{1/(k_s a_s) + 1/k} \quad (7-95)$$

$$k_{\text{obs}} = \frac{1}{1/(k_s a_s) + 1/k}$$

Hence the observable overall rate constant  $k_{\text{obs}}$  is actually a combination of the mass-transfer coefficient and the intrinsic rate

## 7-20 REACTION KINETICS

coefficient; or in terms of resistances (in units of time) the overall resistance is the sum of the mass transfer and intrinsic kinetic resistance. For this first-order rate case, the overall behavior remains first order in bulk gas concentration. The two limiting cases are mass transfer and reaction control, respectively:

$$\begin{aligned} k_{\text{obs}} &= k_s a_s & \text{and } r_{\text{obs}} &= k_s a_s C_a & \text{for } k_s a_s \ll k & \text{Mass transfer control} \\ k_{\text{obs}} &= k & \text{and } r_{\text{obs}} &= k C_a & \text{for } k_s a_s \gg k & \text{Kinetic control} \end{aligned} \quad (7-96)$$

The mass-transfer coefficient depends on the geometry of the solid surface, on the hydrodynamic conditions in the vicinity of the catalyst (which are a function, e.g., of the reactor type, geometry, operating conditions, flow regime), and it also depends on the diffusivity of the gas species. Correlations for the mass-transfer coefficient are a large topic and outside the scope of this section. For more details see Bird, Stewart, and Lightfoot, *Transport Phenomena*, 2d ed., John Wiley & Sons, New York, 2002, and relevant sections in this handbook. For non-first-order kinetics a closed-form relationship such as the series of resistances cannot always be derived, but the steady-state assumption of the consecutive mass and reaction steps still applies.

**Intraparticle Diffusion** As indicated above, the larger the catalyst surface area per unit reaction volume  $a_s$ , the larger the overall reaction rate. For a fixed mass of catalyst, decreasing the particle size increases the total external surface area available for the reaction. Another way to increase the surface area is by providing a porous catalyst with lots of internal surface area. The internal structure of the catalyst determines how accessible these internal sites are to the gas-phase reactant and how easily can the products escape back to the gas. The analysis is based on the pseudo-homogeneous reaction diffusion equation, with the gas reactant diffusing through the pores and reacting at active sites inside the catalyst particle. For a first-order irreversible reaction of species A in an infinite slab geometry, the diffusion-reaction equations describe the decreasing reactant concentration from the external surface to the center of the slab:

$$\begin{aligned} D_{ea} \frac{d^2 C_{ay}}{dy^2} - k C_{ay} &= 0 & C_{ay}(L) &= C_{as} \\ \frac{dC_{ay}}{dy} &= 0 \end{aligned} \quad (7-97)$$

The concept of effectiveness factor has been developed to calculate the overall reaction rate in terms of the concentration at the external surface  $C_{as}$ :

$$r = \eta k C_{as} \quad (7-98)$$

Hence the effectiveness factor is the ratio of the actual rate to that if the reactions were to occur at the external surface concentration, i.e., in absence of intraparticle diffusion resistance:

$$\eta = \frac{(1/L) \int_0^L r(C_{ay}) dy}{r(C_{as})} = \frac{\text{rate with pore diffusion resistance}}{\text{rate at external surface conditions}} \quad (7-99)$$

The effectiveness factor can be written as a function of a dimensionless independent variable called the Thiele modulus, which for a first-order reaction is defined below together with the corresponding effectiveness factor derived by integration of the corresponding diffusion-reaction equation (7-97):

$$\phi_{\text{slab}} = L \sqrt{\frac{k}{D_{ea}}} \quad \eta = \frac{\tanh \phi_{\text{slab}}}{\phi_{\text{slab}}} \quad (7-100)$$

Since the model is pseudo-homogeneous, there is no distinction

between the gas-filled pores and the solid parts of the particle. For most catalysts (except for straight channel monoliths), the diffusion path is not straight and has varying cross section. Hence, the effective diffusivity of A is defined based on the catalyst internal structure and the gas diffusivity of A in the gas mixture as follows:

$$D_{ea} = \frac{\epsilon_s}{\tau} D_a \quad (7-101)$$

The parameters that describe the pore structure are the porosity  $\epsilon_s$ , accounting for the fact that diffusion only occurs through the gas-filled part of the particle, and the tortuosity  $\tau$  accounting for the effect of diffusion path length and contraction/expansion of pores along the diffusion path. The diffusion regime depends on the diffusing molecule, pore size, and operating conditions (concentration, temperature, pressure), and this can be visualized in Fig. 7-7. As indicated, the effective diffusion coefficient ranges over many orders of magnitude from very low values in the configurational regime (e.g., in zeolites) to high values in the regular regime.

There is a large body of literature that deals with the proper definition of the diffusivity used in the intraparticle diffusion-reaction model, especially in multicomponent mixtures found in many practical reaction systems. The reader should consult references, e.g., Bird, Stewart, and Lightfoot, *Transport Phenomena*, 2d ed., John Wiley & Sons, New York, 2002; Taylor and Krishna, *Multicomponent Mass Transfer*, Wiley, 1993; and Cussler, *Diffusion Mass Transfer in Fluid Systems*, Cambridge University Press, 1997.

The larger the characteristic length  $L$ , the larger the Thiele modulus, the smaller the effectiveness factor, and the steeper the reactant concentration profile in the catalyst particle. A generalized characteristic length definition  $V_p/S_{px}$  (particle volume/external particle surface area) brings together the  $\eta$ - $\phi$  curves for a variety of particle shapes, as illustrated in Table 7-6 and Fig. 7-8 for for slabs, cylinders, and spheres. Here  $I_0$  and  $I_1$  are the corresponding modified Bessel functions of the first kind.

Further generalization of the Thiele modulus and effectiveness factor for a general global reaction and various shapes is

$$\phi = \frac{(V_p/S_{px}) r_a(C_{as})}{\sqrt{\frac{1}{2} \int_{C_{ae}}^{C_{as}} D_{ea}(C_{ay}) r_a(C_{ay}) dC_{ay}}} \quad (7-102)$$

In Eq. (7-102) component A is the limiting reactant. For example, for an  $n$ th-order irreversible reaction

$$\phi = \frac{V_p}{S_{px}} \sqrt{\frac{(n+1) k C_{as}^{n-1}}{2 D_{ea}}} \quad (7-103)$$

This generalized Thiele modulus works well with the effectiveness factors for low and high values of the Thiele modulus, but it is not as accurate for intermediate values. However, these differences are not significant, given the uncertainties associated with measuring some of the other key parameters that go into the calculation of the Thiele modulus, e.g., the effective diffusivity and the intrinsic rate constant.

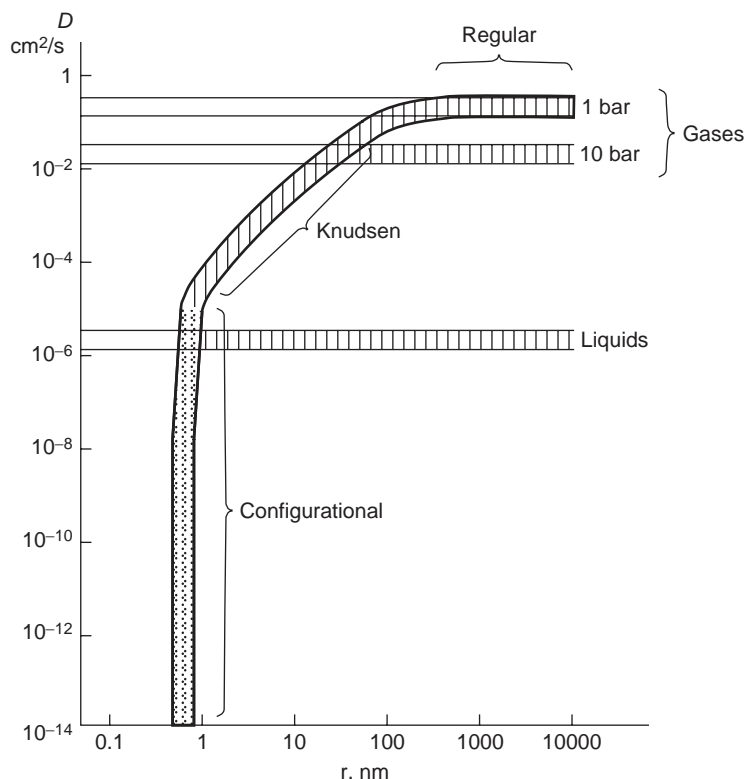

**Effect of Intraparticle Diffusion on Observed Order and Activation Energy** Taking the  $n$ th-order reaction case in the limit of intraparticle diffusion control, i.e., large Thiele modulus, the effectiveness factor is

$$\eta = \frac{1}{\phi} \quad (7-104)$$

the observed rate is

$$r_{\text{obs}} = \eta r = \frac{S_{px}}{V_p} \sqrt{\frac{2 D_{ea} k}{(n+1)}} C_{as}^{(n+1)/2} \quad (7-105)$$

**FIG. 7-7** Diffusion regimes in heterogeneous catalysts. [From Weisz, *Trans. Fara. Soc.* **69**: 1696–1705 (1973); Froment and Bischoff, *Chemical Reactor Analysis and Design*, Wiley, 1990, Figure 3.5.1-1.]

and the observed rate constant is

$$k_{\text{obs}} = \eta k = \frac{S_{px}}{V_p} \sqrt{\frac{2}{n+1} D_{\text{eff}} e^{(E_D/RT)} k_0 e^{(E/RT)}} \quad (7-106)$$

Hence, the observed order and activation energy differ from those of the intrinsic  $n$ th-order kinetics:

$$n_{\text{obs}} = \frac{n+1}{2} \quad E_{\text{obs}} = \frac{E + E_D}{2} \approx \frac{E}{2} \quad (7-107)$$

Here  $E_D$  is the activation energy for diffusion.

**TABLE 7-6 Effectiveness Factors for Different Shapes for a First-Order Reaction**

| Shape             | $V_p/S_{px}$ | Effectiveness factor $\eta$  |
|-------------------|--------------|--|
| Infinite slab     | $R$          | $\frac{\tanh \phi}{\phi}$  |
| Infinite cylinder | $R/2$        | $\frac{I_1(2\phi)}{\phi I_0(2\phi)}$                                   |
| Sphere            | $R/3$        | $\frac{1}{\phi} \left( \frac{3}{\tanh 3\phi} - \frac{1}{\phi} \right)$ |

The observed and intrinsic reaction order is the same under intraparticle diffusion control only for a first-order reaction. Weisz and Prater [“Interpretation of Measurements in Experimental Catalysis,” *Adv. Catal.* **6**: 144 (1954)] developed general estimates for the observed order and activation energy over the entire range of  $\phi$ :

$$n_{\text{obs}} = n + \frac{n-1}{2} \frac{d \ln \eta}{d \ln \phi} \quad E_{\text{obs}} = E + \frac{E - E_D}{2} \frac{d \ln \eta}{d \ln \phi} \quad (7-108)$$

Weisz and Prater [“Interpretation of Measurements in Experimental Catalysis,” *Adv. Catal.* **6**: 144 (1954)] also developed a general criterion for diffusion limitations, which can guide the lab analysis of rate data:

$$\text{If } \Phi = \left( \frac{3V_p}{S_{px}} \right)^2 \frac{r_{\text{obs}}}{D_{\text{eff}} C_{\text{as}}} \gg 1 \text{ then diffusion-limited} \\ \ll 1 \text{ then no diffusional resistance} \quad (7-109)$$

#### Effect of Intraparticle Diffusion for Reaction Networks

For multiple reactions, intraparticle diffusion resistance can also affect the observed selectivity and yield. For example, for consecutive reactions intraparticle diffusion resistance reduces the yield of the intermediate (often desired) product if both reactions have the same order. For parallel reactions diffusion resistance reduces the selectivity to the higher-order reaction. For more details see, e.g., Carberry, *Chemical and Catalytic Reaction Engineering*, McGraw-Hill, 1976; and Levenspiel, *Chemical Reaction Engineering*, 3d ed., Wiley, 1999.

FIG. 7-8 Effectiveness factors for a slab (P), a cylinder (C), and a sphere (S). [Adapted from Fig. 1 in Aris and Bester, "The Effect of Shape on the Effectiveness Factor," Chem. Eng. Sci. **24**: 793 (1969).]

For more complex reactions, the effect of intraparticle diffusion resistance on rate, selectivity, and yield depends on the particulars of the network. Also, the use of the Thiele modulus–effectiveness factor relationships is not as easily applicable, and numerical solution of the diffusion-reaction equations may be required.

**Intraparticle Diffusion and External Mass-Transfer Resistance** For typical industrial conditions, external mass transfer is important only if there is substantial intraparticle diffusion resistance. This subject has been discussed by Luss, "Diffusion-Reaction Interactions in Catalyst Pellets," in Carberry and Varma (eds.), *Chemical Reaction and Reactor Engineering*, Dekker, 1987. This, however, may not be the case for laboratory conditions, and care must be exerted in including the proper data interpretation. For instance, for a spherical particle with both external and internal mass-transfer limitations and first-order reaction, an overall effectiveness factor  $\eta_i$  can be derived, indicating the series-of-resistances nature of external mass transfer followed by intraparticle diffusion-reaction:

$$\frac{1}{\eta_i} = \frac{1}{\eta} + \frac{\phi^2}{3Sh'} \quad (7-110)$$

$$Sh' = \frac{\epsilon k_p R}{D_{ea}} \quad (7-111)$$

As indicated above, intraparticle diffusion lowers the apparent activation energy. The apparent activation energy is even further lowered under external mass-transfer control. Figure 7-9 illustrates how the rate-controlling step changes with temperature, and as a result the dependence of the apparent first-order rate constant on temperature also changes, from a very strong dependence under kinetic control to virtual independence under external mass-transfer control.

Note that in the limit of external diffusion control, the activation energy  $E_{obs} \rightarrow 0$ , as can be shown when substituting Eq. (7-110) in Eq. (7-108). For more details on how to represent the combined effect of external and intraparticle diffusion on effectiveness factor for more complex systems, see Luss, "Diffusion-Reaction Interactions in Catalyst Pellets."

**Heat-Transfer Resistances** A similar analysis regarding external and intraparticle heat-transfer limitations leads to temperature

gradients which add further complexity to the behavior of heterogeneous catalytic systems, including steady-state multiplicity. More details are given in Sec. 19.

**Catalyst Deactivation** The catalyst life ranges from seconds to minutes to a few days to several years, as the active surface of a catalyst is degraded by chemical, thermal, or mechanical factors. *Chemical deactivation* occurs due to feed or product poisoning or masking. Poisoning may be due to compounds such as P, S, As, Na, and Bi that have free electron pairs and is generally considered irreversible. In some cases a reduced life is simply accepted, as in the case of slow accumulation of trace metals from feed to catalytic cracking; but in other cases the deactivation is too rapid. Sulfur and water are removed from feed to ammonia synthesis, sulfur from feed to platinum reforming, and arsenic from feed to  $SO_2$  oxidation with platinum. Masking may be due to covering of the active sites by contaminants in either the feed or products. Examples of feed masking agents can include Si (from organic silicons) and rust. An example of product masking is coking. Reactivation sometimes is done in place;

FIG. 7-9 Dependence of the rate-controlling step on temperature.

for instance, coke is burned off cracking catalyst or off nickel and nickel-molybdenum catalysts in a fluidized reactor/regenerator system. *Thermal deactivation* is primarily due to rearrangement of the active sites at high temperature due to *sintering*. Sintering results in agglomeration of active ingredients (lower dispersion). In most cases sintering is irreversible; however Pt/Al<sub>2</sub>O<sub>3</sub> catalysts have been regenerated in place by Cl<sub>2</sub> treatment. The catalyst also can be modified by additives, for instance, chromia to nickel to prevent sintering, rhenium to platinum to reduce coking, and so on. *Mechanical deactivation* may be caused by attrition or erosion and subsequent loss of catalyst as fines. The attrition resistance of catalysts is related to the nature of the support and its porosity.

For additional references, see, e.g., Thomas, *Catalytic Processes and Proven Catalysts*, Academic Press, 1970; Butt and Petersen, *Activation, Deactivation and Poisoning of Catalysts*, Academic Press, 1988; and Delmon and Froment, *Catalyst Deactivation*, Elsevier, 1980.

The *activity*  $\alpha$  at any time on stream may be simply defined as the ratio of the rate at time  $t$  to the rate with fresh catalyst

$$\alpha = \frac{r(t)}{r(t=0)} \quad (7-112)$$

The rate of destruction of active sites and pore structure can be expressed as a kinetic relation that can be generally first- or second-order. For instance, for a second-order dependence,

$$\frac{d\alpha}{dt} = -k_d\alpha^2 \quad (7-113)$$

the corresponding integral is

$$\alpha = \frac{1}{1 + k_d t} \quad (7-114)$$

This type of deactivation mechanism often applies catalyst sintering and coke deactivation. The deactivation rate constant is expected to have an Arrhenius dependence on temperature.

When the feedstock contains constant proportions of reactive impurities, the rate of decline may also depend on the concentration of the main reactant, e.g., for a power law rate

$$\frac{d\alpha}{dt} = -k_d\alpha^p C^q \quad (7-115)$$

Such a differential equation must be solved simultaneously with a rate equation for the main reactant.

The deactivation rate constants are estimated by methods like those for finding constants of any rate equation, given suitable ( $\alpha$ ,  $t$ ) data. There are different chemical deactivation mechanisms—two of the most common are described below. For more details see Butt and Petersen, *Activation, Deactivation and Poisoning of Catalysts*, Academic Press, 1988; and Froment and Bischoff, *Chemical Reactor Analysis and Design*, Wiley, 1990. In *uniform deactivation*, the poison is distributed uniformly throughout the pellet and degrades it gradually. In *pore mouth (shell progressive) poisoning*, the poison is so effective that it kills the active site as it enters the pore; hence complete deactivation begins at the mouth and moves gradually inward.

**Uniform Deactivation** When uniform deactivation occurs, the specific rate declines by a factor  $1 - \beta$ , where  $\beta$  is the fractional poisoning.  $\beta$  is calculated from the poisoning rate, and it is often assumed to be proportional to the concentration of the poison in the bulk fluid. Then a power law rate equation becomes

$$r = k(1 - \beta)\eta C_s^n \quad (7-116)$$

The effectiveness depends on  $\beta$  through the Thiele modulus

$$\phi = L\sqrt{\frac{k(1 - \beta)C_s^{n-1}}{D_e}} \quad (7-117)$$

To find the effectiveness under poisoned conditions, this form of the Thiele modulus is substituted into the appropriate relation for effectiveness. For example, for a first-order reaction in slab geometry, the effectiveness factor is

$$\eta = \frac{\tanh \phi}{\phi} = \frac{\tanh[L\sqrt{k(1 - \beta)/D_e}]}{L\sqrt{k(1 - \beta)/D_e}} \quad (7-118)$$

Figure 7-10a shows the ratio of the effectiveness factor with uniform poisoning to that without poisoning versus the fraction poisoned for the above case of first-order reaction in a slab.

**Pore Mouth (or Shell Progressive) Poisoning** This mechanism occurs when the poisoning of a pore surface begins at the mouth of the pore and moves gradually inward. This is a moving boundary problem, and the pseudo-steady-state assumption is made that the boundary moves slowly compared with diffusion of poison and reactants and reaction on the active surface.  $\beta$  is the fraction of the pore that is deactivated. The poison diffuses through the dead zone and deposits at the interface between the dead and active zones. The reactants diffuse across the dead zone without reaction, followed by diffusion-reaction in the active zone.

Figure 7-10b shows simulation results for the ratio of the effectiveness factor with pore mouth poisoning to that without poisoning for a first-order reaction in a slab.

## GAS-SOLID NONCATALYTIC REACTIONS

Examples of gas-solid noncatalytic reactions include production of iron from iron ores, roasting of sulfide oxides, combustion of solid fuels, chlorination of Ti ores to make TiCl<sub>4</sub> in the production of TiO<sub>2</sub> pigments, incineration of waste, decomposition of solids to produce gases, e.g., solid propellants and explosives. The kinetic treatment of these reactions has to take into consideration external mass transfer and intraparticle diffusion just as in the case of gas-solid catalytic reactions. However there are major differences, the primary one being consumption of the solid reactant, making the conditions inside the solid particle transient in nature, including change in unreacted particle size, particle density, porosity, etc. For more details see, e.g., Wen ["Noncatalytic Heterogeneous Solid-Fluid Reaction Models," *Ind. Eng. Chem.* **60**(9):34-54 (1968)], Szekeley (in Lapidus and Amundson (eds.), *Chemical Reactor Theory—A Review*, Prentice-Hall, 1977), Doraiswamy and Kulkarni [in Carberry and Varma (eds.), *Chemical Reaction and Reactor Engineering*, Dekker, 1987], and Levenspiel (*Chemical Reaction Engineering*, 3d ed., Wiley, 1999).

The basic steps are identical to those of catalytic gas-solid reactions. However, as indicated above, the process is transient (non-steady-state) due to change in particle size and properties as the reaction progresses.

Several models that describe gas-solid noncatalytic reactions are summarized in Table 7-7. The first two, the sharp interface and volume reaction models, are pseudo-homogeneous, form part of the class of shrinking core models, and can be treated by using the Thiele modulus and effectiveness factor concept. The last three are heterogeneous models.

**Sharp Interface Model** For a first-order reaction in gas reactant,

a rate of conversion of the solid  $B$  per unit particle volume of

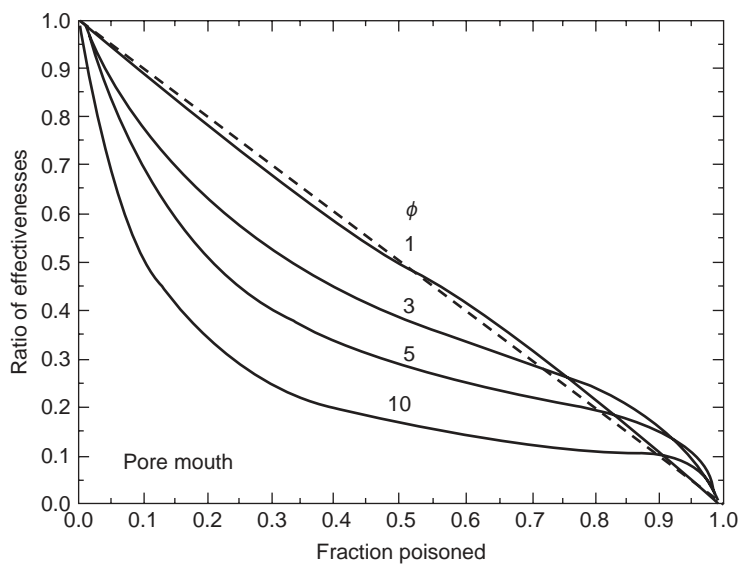

$$r_b = kC_{a0}C_s \quad (7-120)$$

and assuming pseudo-steady state for the gas-phase component, it can be shown that

$$r_{\text{obs}} = \frac{C_{a0}}{\frac{1}{k_p a_p} + \frac{R_p^2}{D_{ca}} \left( \frac{R_p}{R_s} - 1 \right) + \frac{b}{kC_{a0}}} \quad (7-121)$$

(a)

(b)

**FIG. 7-10** Poisoning of a first-order reaction. (a) Uniform poisoning. (b) Pore mouth poisoning.

where  $R_p$  and  $R_s$  are the particle and solid core radii,  $a_p$  is the external particle diameter-based interfacial area per particle volume, and  $k$  is based on particle volume. Equation (7-121) represents three resistances in series—external mass transfer, diffusion in the reacted (ash) zone, and reaction at the unreacted solid-ash interface.

The conversion of the solid reactant  $B$  is obtained from integration of the pseudo-steady-state diffusion model with reaction at the boundary:

$$\begin{aligned} \frac{1}{r^2} \frac{\partial}{\partial r} \left( D_{ea} r^2 \frac{\partial C_{as}}{\partial r} \right) &= 0 \\ D_{ea} \frac{\partial C_{as}}{\partial r} &= \frac{1}{b} k C_{as} C_s \quad \text{at } r = R_s, \\ D_{ea} \frac{\partial C_{as}}{\partial r} &= k_s (C_{a0} - C_{as}) \quad \text{at } r = R_p \end{aligned} \quad (7-122)$$

**TABLE 7-7 Noncatalytic Gas-Solid Reaction-Diffusion Models**

| Model                       | Main features   |
|-----------------------------|---|
| Sharp interface model (SIM) | Reacting solid is nonporous.<br>Reacted solid ash is porous.<br>Reaction occurs at the ash-unreacted solid interface.   |
| Volume reaction model       | Reacting solid is also porous.<br>Reaction occurs everywhere in the particle.   |
| Grain model                 | Particle is divided into identical solid spherical grains.<br>Each grain reacts according to the sharp interface model. |
| Crackling core model        | Combination of SIM and grain model.   |
| Nucleation model            | Nucleation of metals in metal reduction reactions.  |

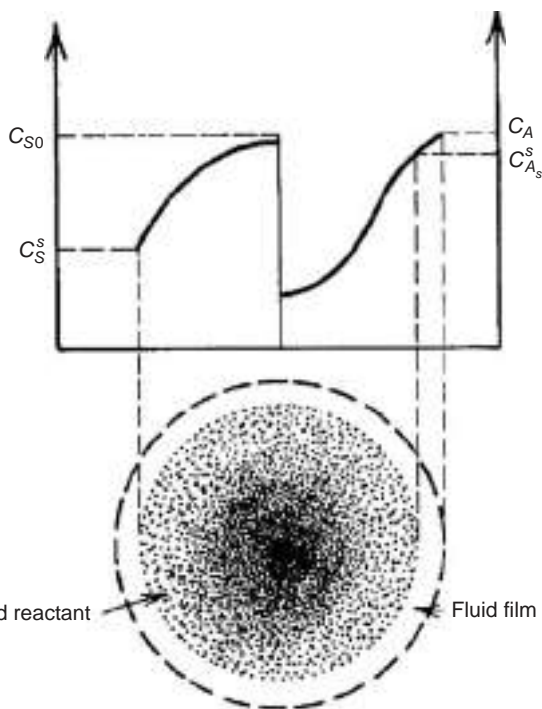

The moving boundary radius  $R_c$  is determined from a material balance that relates the unreacted solid volume to the reaction rate. Integration gives the time  $\tau$  required to achieve a given conversion of the solid  $B$ ,  $X_b$ :

$$\tau = \frac{R_p C_{s0}}{b C_{a0}} \left\{ \frac{1}{3} \left( \frac{1}{k_s} - \frac{R_p}{D_{ea}} \right) X_b + \frac{R_p}{2 D_{ea}} \left[ 1 - (1 - X_b)^{2/3} \right] + \frac{3b}{C_{s0} R_p k} \left[ 1 - (1 - X_b)^{1/3} \right] \right\} \quad X_b = 1 - \left( \frac{R_c}{R_p} \right)^3 \quad (7-123)$$

Similar solutions can be obtained for other shapes (Doraiswamy and Kulkarni, in Carberry and Varma (eds.), *Chemical Reaction and Reactor Engineering*, Dekker, 1987). Figure 7-11 shows typical concentration profiles for this case.

**FIG. 7-11** Sharp interface model—concentration profiles. [From Wen, "Noncatalytic Heterogeneous Solid-Fluid Reaction Models," *Ind. Eng. Chem.* **60**(9): 34-54 (1968), Fig. 1.]

**FIG. 7-12** Typical concentration profiles for the volume reaction model. [From Wen, "Noncatalytic Heterogeneous Solid-Fluid Reaction Models," *Ind. Eng. Chem.* **60**(9): 34-54 (1968), Fig. 3.]

**Volume Reaction Model** A typical concentration profile for the volume reaction model is shown in Fig. 7-12.

A general transient model of diffusion-reaction that uses the effective diffusivity concept described for gas-solid catalytic reactions can be derived here as well, e.g., for a spherical particle:

$$\frac{\partial(\epsilon_s C_{as})}{\partial t} = \frac{1}{r^2} \frac{\partial}{\partial r} \left( D_{ea} r^2 \frac{\partial C_{as}}{\partial r} \right) - r_a \quad \frac{\partial C_s}{\partial t} = -r_s$$

$$C_{as} = C_{as0} \quad C_s = C_{s0} \quad \text{at } t = 0 \quad \frac{\partial C_{as}}{\partial r} = 0 \quad \text{at } r = 0$$

$$D_{ea} \frac{\partial C_{as}}{\partial r} \Big|_{r=R} = k_s (C_a - C_{as}|_{r=R}) \quad (7-124)$$

$$\epsilon_s = \epsilon_{s0} + C_{s0}(v_s - v_p) \left( 1 - \frac{C_s}{C_{s0}} \right) \quad \frac{D_{ea}}{D_{ea0}} = \left( \frac{\epsilon_s}{\epsilon_{s0}} \right)^\beta, \quad \beta = 2 - 3 \quad (7-125)$$

Here the porosity and the diffusivity vary with conversion of solid;  $v_s$  and  $v_p$  are the reactant and product molar volumes. A Thiele modulus  $\phi$  and dimensionless time  $\theta$  can be defined, e.g., for a rate second-order in A and first-order in S:

$$r = k C_a^2 C_s \quad (7-126)$$

$$\phi = R \sqrt{\frac{k C_{as}(R) C_{s0}}{D_{ea0}}} \quad \theta = b k C_{as0} t \quad (7-127)$$

For the given rate expression, equations (7-124) to (7-127) can be numerically integrated, e.g., in Fig. 7-13 for reaction control and Fig. 7-14 for intraparticle diffusion control, both with negligible external mass-transfer resistance;  $x$  is the fractional conversion.

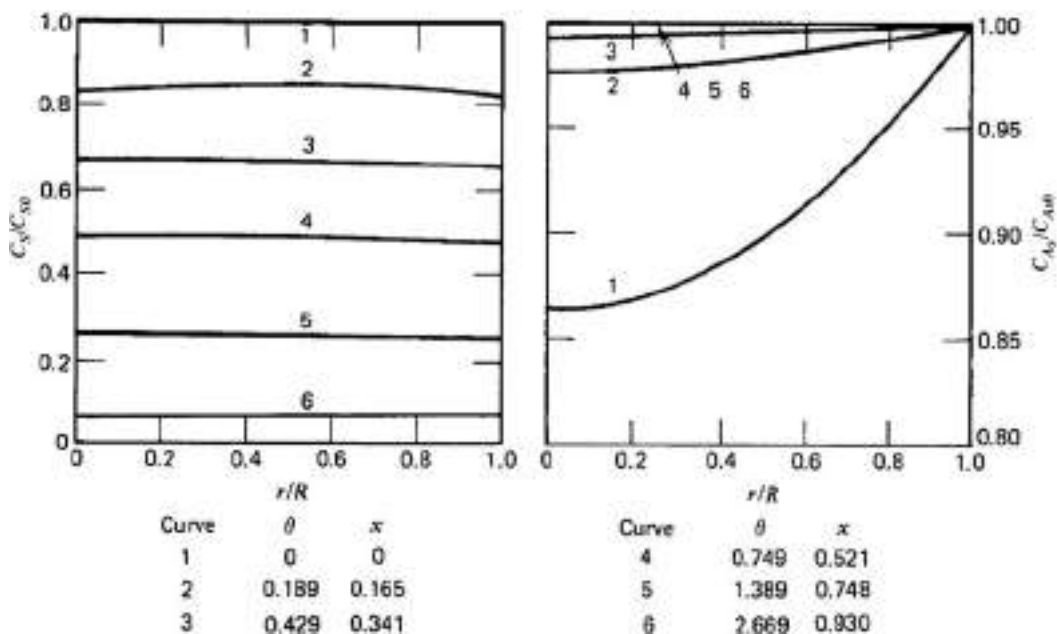

FIG. 7-13 Concentration profiles with reaction control  $\phi = 1$ , in absence of gas particle mass-transfer resistance. [From Wen, "Noncatalytic Heterogeneous Solid-Fluid Reaction Models," Ind. Eng. Chem. **60**(9): 34-54 (1968), Fig. 11.]

FIG. 7-14 Concentration profiles with intraparticle diffusion control,  $\phi = 70$ , in absence of gas particle mass-transfer resistance. [From Wen, "Noncatalytic Heterogeneous Solid-Fluid Reaction Models," Ind. Eng. Chem. **60**(9): 34-54 (1968), Fig. 12.]

## GAS-LIQUID REACTIONS

Many industrial processes employ gas-liquid reactions that can be either noncatalytic or homogeneously catalyzed. These include, for instance, absorption of acid gases (SO<sub>3</sub>, NO<sub>2</sub>, CO<sub>2</sub>), chlorinations (benzene, dodecane, toluene), oxidations (P-Xylene to terephthalic acid, cyclohexane to cyclohexanone and cyclohexanol, acetaldehyde to acetic acid), hydrogenations (olefins, esters to fatty acids), and hydroformylation of olefins to alcohols, to name a few. See also Sec. 19 and Shah (*Gas-Liquid-Solid Reactor Design*, McGraw-Hill, 1979). These reactions include gas reactants dissolving in a liquid and reacting there with a liquid reactant. When determining the kinetics of such reactions from lab data, one needs to understand the mechanism and the controlling steps, just as was the case for heterogeneous gas-solid reactions. The simplest model is the two-film model, and it involves the following consecutive steps for the gaseous reactant:

1. Mass transfer of gas reactant from bulk gas to the gas-liquid interface across the gas film.
2. At the gas-liquid interface, the liquid and gas concentrations of the gaseous reactant are assumed to be at thermodynamic equilibrium.
3. Mass transfer of the dissolved gas reactant to the bulk liquid across the liquid film—if the reaction is fast, the reaction will occur both in the liquid film (in parallel with diffusion) and in the bulk liquid.

For a volatile liquid reactant or a volatile product, these steps are essentially reversed. For a nonvolatile liquid reactant or product, only the reaction and diffusion in the liquid take place. Figure 7-15 describes the absorbing gas concentration profiles in a gas-liquid system.

For a general gas-liquid reaction:

the two-film pseudo-steady-state model is described by the following fluxes across the interface for the gaseous reactant A:

$$\begin{aligned} N_{aG} &= \frac{D_{aG}}{\delta_G} (P_a - P_{ai}) = k_G (P_a - P_{ai}) = N_{aL} = \frac{D_{aL}}{\delta_L} (C_{Lai} - C_{La}) \\ &= k_L (C_{Lai} - C_{La}) \end{aligned} \quad (7-129)$$

Here the subscript *L* denotes liquid, *G* denotes gas, *i* denotes the gas-liquid interface (where the gas and liquid concentrations are in equilibrium). The thickness of the liquid and gas films is not a directly measurable quantity, and instead mass-transfer coefficients are

defined as indicated above. These depend on the diffusivity of the molecule, geometry, flow, and operating conditions; and typical values can be viewed in Sec. 19. In addition to the two-film steady-state model, other more accurate, non-steady-state models have also been developed such as the surface renewal and penetration models (see, e.g., Astarita, *Mass Transfer with Chemical Reaction*, Elsevier, 1967). In many industrial cases of interest, mass-transfer resistance in the gas-film is negligible, especially considering that gas-phase diffusivities are 2 to 3 orders of magnitude larger for the same species than those in the liquid. Hence we drop the subscripts *L* and *G* from the concentrations since the concentrations considered are in the liquid phase only.

### REACTION-DIFFUSION REGIMES

Depending on the relative rates of diffusion and reaction, the following diffusion-reaction regimes occur:

- $t_D \ll t_r$       slow reaction regime with reaction control
- $t_D \gg t_r$       fast reaction regime with diffusion control
- $t_D \approx t_r$       both reaction and diffusion are important

$$t_D = \frac{D_a}{k_L^2} \qquad t_r = \frac{C_{ai} - C_{ae}}{r(C_{ai})} \quad (7-130)$$

Here  $t_D$  and  $t_r$  are the diffusion and reaction times, respectively, and  $k_L$  is the mass-transfer coefficient in the absence of reaction. For the *fast reaction regime*, diffusion and reaction occur in parallel in the liquid film, while for the *slow reaction regime*, there is no reaction in the liquid film and the mass transfer can be considered to occur independently of reaction in a consecutive manner. For the slow reaction regime, the following subregimes can be defined:

- $t_m \ll t_r$       slow reaction kinetic control
- $t_m \gg t_r$       slow reaction mass-transfer control
- $t_m \approx t_r$       both reaction and mass transfer are important

$$t_m = \frac{1}{k_L a} \quad (7-131)$$

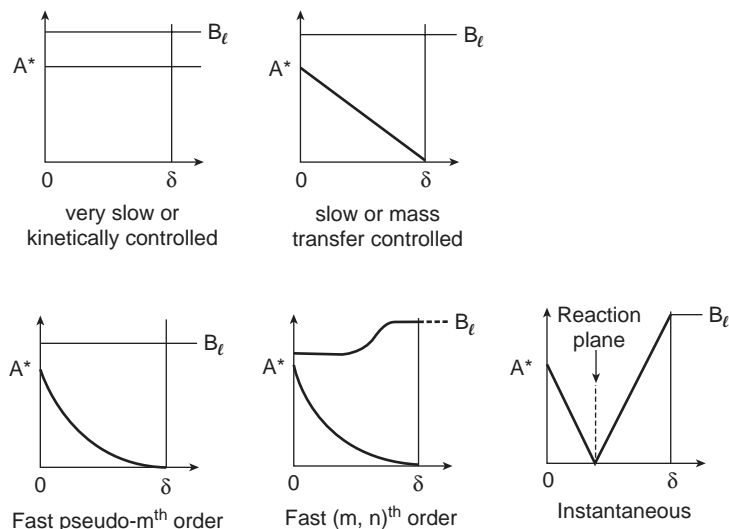

FIG. 7-15 Absorbing gas concentration and temperature profiles (exothermic reaction) in gas-liquid and gas-liquid-solid reactions.

**FIG. 7-16** Concentration profiles for the general reaction  $A(g) + bB(l) \rightarrow \text{products}$  with the rate  $r = kC_a^m C_b^n$ . [Adapted from Mills, Ramachandran, and Chaudhari, "Multiphase Reaction Engineering for Fine Chemicals and Pharmaceuticals," *Rev. Chem. Eng.* 8(1-2):1 (1992), Figs. 19 and 20.]

Here  $t_m$  is the mass-transfer time. Only under *slow reaction kinetic control regime* can intrinsic kinetics be derived directly from lab data. Otherwise the intrinsic kinetics have to be extracted from the observed rate by using the mass-transfer and diffusion-reaction equations, in a manner similar to those defined for catalytic gas-solid reactions. For instance, in the *slow reaction regime*,

$$r_{a,\text{obs}} = \frac{C_{ai}}{He_a/k_G a + 1/k_1 a + 1/k} \quad (7-132)$$

$$k_{\text{obs}} = \frac{1}{He_a/k_G a + 1/k_1 a + 1/k} \quad (7-133)$$

Here  $He_a$  is the Henry constant for the solute  $a$ . For the fast reaction regime, instead of the effectiveness factor adjustment for the intrinsic reaction rate, it is customary to define an *enhancement factor* for mass-transfer enhancement by the reaction, defined as the ratio of mass transfer in presence of reaction in the liquid, to mass transfer in absence of reaction:

$$E = k_l/k_{L0} \quad (7-134)$$

Solving the diffusion-reaction equation in the liquid, the enhancement factor can be related to the *Hatta number*  $Ha$ , which is similar to the Thiele modulus defined for heterogeneous gas-solid catalysts. Thus, the Hatta number and its relation to the controlling regime are

$$Ha = \frac{t_D}{t_R} = \sqrt{\frac{\text{maximum reaction rate in the film}}{\text{maximum mass transfer rate through film}}}$$

$$Ha \ll 1 \quad \text{slow reaction regime} \quad (7-135)$$

$$Ha \gg 1 \quad \text{fast reaction regime}$$

For instance, for a first-order reaction in the gaseous reactant  $A$  (e.g., with large excess of liquid reactant  $B$ ), the following relates the enhancement factor to the Hatta number:

$$Ha = \delta_L \sqrt{\frac{k}{D_a}} = \frac{\sqrt{kD_a}}{k_{L0}} \quad \text{for } C_b \gg C_{ai} \quad (7-136)$$

$$E = \frac{Ha}{\tanh Ha} \left( 1 - \frac{C_a}{C_{ai}} \frac{1}{\cosh Ha} \right) > 1 \quad (7-137)$$

When both  $A$  and  $B$  have comparable concentrations, then the enhancement factor is an increasing function of an additional parameter:

$$\lambda = \frac{D_b C_b}{b D_a C_{ai}} \quad (7-138)$$

In the limit of an instantaneous reaction, the reaction occurs at a plane where the concentration of both reactants  $A$  and  $B$  is zero and the flux of  $A$  equals the flux of  $B$ . The criterion for an instantaneous reaction is

$$Ha^{1/2} \gg \frac{C_b}{b C_{ai}} \quad E_{\infty} = 1 + \lambda \gg 1 \quad (7-139)$$

Figure 7-16 illustrates typical concentration profiles of  $A$  and  $B$  for the various diffusion-reaction regimes.

## GAS-LIQUID-SOLID REACTIONS

### GAS-LIQUID-SOLID CATALYTIC REACTIONS

Many solid catalyzed reactions take place with one of the reactants absorbing from the gas phase into the liquid and reacting with a liquid reactant on the surface or inside the pores of a solid catalyst (see Fig. 7-15). Examples include the Fischer-Tropsch synthesis of hydrocarbons from synthesis gas ( $\text{CO}$  and  $\text{H}_2$ ) in the presence of  $\text{Fe}$  or  $\text{Co}$ -

based heterogeneous catalysts, methanol synthesis from synthesis gas ( $\text{H}_2 + \text{CO}$ ) in the presence of heterogeneous  $\text{CuO/ZnO}$  catalyst, and a large number of noble metal catalyzed hydrogenations among others. For a slow first-order reaction of a gaseous reactant, the concept of resistances in series can be expanded as follows, e.g., for a slurry reactor with fine catalyst powder:

$$r_{a,obs} = \frac{C_{ai}}{\frac{H_e}{k_{ca}} + \frac{1}{k_{la}} + \frac{1}{k_{as}} + \frac{1}{k}} \quad k_{obs} = \frac{1}{\frac{H_e}{k_{ca}} + \frac{1}{k_{la}} + \frac{1}{k_{as}} + \frac{1}{k}} \quad (7-140)$$

Intraparticle diffusion resistance may become important when the particles are larger than the powders used in slurry reactors, such as for catalytic packed beds operating in trickle flow mode (gas and liquid downflow), in upflow gas-liquid mode, or countercurrent gas-liquid mode. For these the effectiveness factor concept for intraparticle diffusion resistance has to be considered in addition to the other resistances present. See more details in Sec. 19.

## POLYMERIZATION REACTIONS

Polymers are high-molecular-weight compounds assembled by the linking of small molecules called monomers. Most polymerization reactions involve two or three phases, as indicated below. There are several excellent references dealing with *polymerization kinetics* and reactors, including Ray in Lapidus and Amundson, (eds.), *Chemical Reactor Theory—A Review*, Prentice-Hall, 1977; Tirrel et al. in Carberry and Varma (eds.), *Chemical Reaction and Reactor Engineering*, Dekker, 1987; and Meyer and Keurentjes (eds.), *Handbook of Polymer Reaction Engineering*, Wiley, 2005.

Polymerization can be classified according to the main phase in which the reaction occurs as liquid (most polymerizations), vapor (e.g., Ziegler Natta polymerization of olefins), and solid phase (e.g., finishing of melt step polymerization). Polymerization reactions occur in liquid phase and can be further subclassified into

1. Bulk mass polymerization:
  - a. Polymer soluble in monomer
  - b. Polymer insoluble in monomer
  - c. Polymer swollen by monomer
2. Solution polymerization
  - a. Polymer soluble in solvent
  - b. Polymer insoluble in solvent
3. Suspension polymerization with initiator dissolved in monomer
4. Emulsion polymerization with initiator dissolved in dispersing medium

Polymerization can be catalytic or noncatalytic, and can be homogeneously or heterogeneously catalyzed. Polymers that form from the liquid phase may remain dissolved in the remaining monomer or solvent, or they may precipitate. Sometimes beads are formed and remain in suspension; sometimes emulsions form. In some processes solid polymers precipitate from a fluidized gas phase. Polymerization processes are also characterized by extremes in temperature, viscosity, and reaction times. For instance, many industrial polymers are mixtures with molecular weights of  $10^4$  to  $10^7$ . In polymerization of styrene the viscosity increased by a factor of  $10^6$  as conversion increased from 0 to 60 percent. The adiabatic reaction temperature for complete polymerization of ethylene is 1800 K (3240°R). Initiators of the chain reactions have concentration as low as  $10^{-8}$  g·mol/L, so they are highly sensitive to small concentrations of poisons and impurities.

Polymerization mechanism and kinetics require special treatment and special mathematical tools due to the very large number of similar reaction steps. Some polymerization types are briefly described next.

**Bulk Polymerization** The monomer and initiators are reacted with or without mixing, e.g., without mixing to make useful shapes directly. Because of viscosity limitations, stirred bulk polymerization is not carried to completion. For instance, for addition polymerization conversions as low as 30 to 60 percent are achieved, with the remaining monomer stripped out and recycled (e.g., in the case of polystyrene).

**Bead Polymerization** Bulk reaction proceeds in droplets of 10- to 1000- $\mu\text{m}$  diameter suspended in water or other medium and insulated from each other by some colloid. A typical suspending agent is polyvinyl alcohol dissolved in water. The polymerization can be done to high conversion. Temperature control is easy because of the moderating thermal effect of the water and its low viscosity. The suspensions sometimes are unstable and agitation may be critical. Examples

are polyvinyl acetate in methanol, copolymers of acrylates and methacrylates, and polyacrylonitrile in aqueous  $\text{ZnCl}_2$  solution.

**Emulsion Polymerization** Emulsions have particles of 0.05- to 5.0- $\mu\text{m}$  diameter. The product is a stable latex, rather than a filterable suspension. Some latexes are usable directly, as in paints, or they may be coagulated by various means to produce very high-molecular-weight polymers. Examples are polyvinyl chloride and butadiene-styrene rubber.

**Solution Polymerization** These processes may retain the polymer in solution or precipitate it. Examples include polyethylene, the copolymerization of styrene and acrylonitrile in methanol, the aqueous solution of acrylonitrile to precipitate polyacrylonitrile.

**Polymer Characterization** The physical properties of polymers depend largely on the *molecular weight distribution (MWD)*, which can cover a wide range. Since it is impractical to fractionate the products and reformulate them into desirable ranges of molecular weights, immediate attainment of desired properties must be achieved through the correct choice of reactor type and operating conditions, notably of distributions of residence time and temperature. High viscosities influence those factors. For instance, high viscosities prevalent in bulk and melt polymerizations can be avoided with solution, bead, or emulsion operations. The interaction between the flow pattern in the reactor and the type of reaction affects the MWD. If the period during which the molecule is growing is short compared with the residence time in the reactor, the MWD in a batch reactor is broader than in a CSTR. This situation holds for many free radical and ionic polymerization processes where the reaction intermediates are very short lived. In cases where the growth period is the same as the residence time in the reactor, the MWD is narrower in batch than in CSTR. Polymerizations that have no termination step—for instance, polycondensations—are of this type. This topic is treated by Denbigh [*J. Applied Chem.*, 1:227(1951)].

Four types of MWD can be defined: (1) The *number chain length distribution (NCLD)*, relating the chain length distribution to the number of molecules per unit volume; (2) the *weight chain length distribution (WCLD)* relating the chain length distribution to the weight of molecules per unit volume; (3) the *number molecular weight distribution (NMWD)* relating the chain length distribution to molecular weight; and (4) the *weight molecular weight distribution (WMWD)* relating the weight distribution to molecular weight. Two average molecular weights and corresponding average chain lengths are typically defined: the *number average molecular weight*  $M_n$  and the corresponding *number average chain length*  $\mu_n$ ; and the *weight average molecular weight*  $M_w$  and the corresponding *weight average chain length*  $\mu_w$ . Their ratio is called *polydispersity* and describes the width of the molecular weight distribution.

$$M_n = \frac{w \sum_{j=1}^{\infty} j P_j}{\sum_{j=1}^{\infty} P_j} \quad \mu_n = \frac{\sum_{j=1}^{\infty} j P_j}{\sum_{j=1}^{\infty} P_j} \quad M_w = \frac{w \sum_{j=1}^{\infty} j^2 P_j}{\sum_{j=1}^{\infty} j P_j} \quad \mu_w = \frac{\sum_{j=1}^{\infty} j^2 P_j}{\sum_{j=1}^{\infty} j P_j}$$

$$\text{polydispersity} = \frac{M_w}{M_n} = \frac{\mu_w}{\mu_n} \quad (7-141)$$

The average chain lengths can be related to the *moments*  $\lambda_k$  of the distribution as follows:

$$\mu_n = \frac{\lambda_1}{\lambda_0} \quad \mu_w = \frac{\lambda_2}{\lambda_1} \quad \text{polydispersity} = \frac{\lambda_0 \lambda_2}{\lambda_1^2} \quad \lambda_k = \sum_{j=1}^{\infty} j^k P_j \quad (7-142)$$

Here  $P_j$  is the concentration of the polymer with chain length  $j$ —the same symbol is also used for representing the polymer species  $P_j$ ;  $w$  is the molecular weight of the repeating unit in the chain.

A factor in addition to the residence time distribution and temperature distribution that affects the molecular weight distribution is the type of the chemical reaction (e.g., step or addition polymerization).

Two major polymerization mechanisms are considered: *chain growth* and *step growth*. In addition, polymerization can be *homopolymerization*—a single monomer is used—and *copolymerization* usually with two monomers with complementary functional groups.

**Chain Homopolymerization Mechanism and Kinetics** Free radical and ionic polymerizations proceed through this type of mechanism, such as styrene polymerization. Here one monomer molecule is added to the chain in each step. The general reaction steps and corresponding rates can be written as follows:

Here  $P_j$  is the *growing* or *live polymer*, and  $M_j$  is the *dead* or *product polymer*. Assuming reaction steps independent of chain length and assuming pseudo-steady-state approximation for the radicals lead to the following rates for monomer and initiator conversion and live polymer distribution. The growing chains distribution is the most probable distribution [see, e.g., Ray in Lapidus and Amundson (eds.), *Chemical Reactor Theory—A Review*, Prentice-Hall, 1977; Tirrel et al. in Carberry and Varma (eds.), *Chemical Reaction and Reactor Engineering*, Dekker, 1987]:

$$\begin{aligned}
 P_n &= (1 - \alpha)P\alpha^{n-1} \quad \alpha = \frac{k_p M}{(k_p + k_t)M + (k_{tc} + k_{td})P} \\
 P &= \left( \frac{2fk_d I}{k_{tc} + k_{td}} \right)^{1/2} \quad \frac{dI}{dt} = -k_d I \quad (7-144) \\
 r = \frac{dM}{dt} &= -k_p \left( \frac{2fk_d}{k_{tc} + k_{td}} \right)^{1/2} I^{1/2} M \quad DP_n^{\text{inst}} = \frac{k_p M}{(0.5k_{tc} + k_{td})P}
 \end{aligned}$$

Here  $r$  is the rate of polymerization,  $\alpha$  is the *probability of propagation*,  $DP_n^{\text{inst}}$  is the *instantaneous degree of polymerization*, i.e., the number of monomer units on the dead polymer, and  $f$  is the *initiation efficiency*. Compare  $r$  in Eq. (7-144) with the simpler Eq. (7-68). When chain transfer is the primary termination mechanism, such as in anionic polymerization, then the polydispersity is 2.

Mathematically, the infinite set of equations describing the rate of each chain length can be solved by using the  $z$  transform method (a discrete method), *continuous variable approximation method*, or the *method of moments* [see, e.g., Ray in Lapidus and Amundson (eds.), *Chemical Reactor Theory—A Review*, Prentice-Hall, 1977].

Typical ranges of the kinetic parameters for low conversion homopolymerization are given in Table 7-8. For more details see Hutchenson in Meyer and Keurentjes (eds.), *Handbook of Polymer Reaction Engineering*, Wiley, 2005.

#### Step Growth Homopolymerization Mechanism and Kinetics

Here any two growing chains can react with each other. The propagation mechanism is an infinite set of reactions:

**TABLE 7-8 Typical Ranges of Kinetic Parameters**

| Coefficient/concentration | Typical range         |
|---------------------------|-----------------------|
| $k_{ds}$ , 1/s            | $10^{-6}$ – $10^{-4}$ |
| $f$                       | 0.4–0.9               |
| $k_p$ , L/(mol/s)         | $10^2$ – $10^4$       |
| $k_t$ , L/(mol/s)         | $10^6$ – $10^8$       |
| $k_{tr}/k_p$              | $10^{-6}$ – $10^{-4}$ |
| $I$ , mol/L               | $10^{-4}$ – $10^{-2}$ |
| $M$ , mol/L               | 1–10                  |

SOURCE: Hutchenson, "Typical Ranges of Kinetic Parameters," in *Handbook of Reaction Engineering*, Wiley, 2005, Table 4.1.

For instance, some nylons are produced through this mechanism. This is usually modeled under the simplifying assumption that the rate constants are independent of chain length. This assumption was proved pretty accurate, and by using the  $z$  transform it results in the *Flory distribution*:

$$\begin{aligned}
 P_n &= \frac{P_{10}(P_{10}\tau)^{n-1}}{(P_{10}\tau + 1)^{n+1}} \quad n \geq 1 \quad k_{pnm} = k_p \quad \text{for all } n, m \quad \tau = \int_0^t k_p M dt \\
 \mu_n &= \frac{2 - \alpha}{1 - \alpha} \quad \mu_w = \frac{2}{(1 - \alpha)(2 - \alpha)} \quad \text{polydispersity} = \frac{\mu_w}{\mu_n} = \frac{2}{(2 - \alpha)^2} \\
 \alpha &= \frac{P_{10}\tau}{P_{10}\tau + 1} \quad (7-146)
 \end{aligned}$$

**Copolymerization** Copolymerization involves more than one monomer, usually two comonomers, as opposed to the single monomer involved in the chain growth and step homopolymerization schemes above. Examples are some nylons, polyesters, and aramids. Here as well there are step growth and chain growth mechanisms, and these are much more complex [see, e.g., Ray in Lapidus and Amundson (eds.), *Chemical Reactor Theory—A Review*, Prentice-Hall, 1977].

## BIOCHEMICAL REACTIONS

Mechanism and kinetics in biochemical systems describe the cellular reactions that occur in living cells. Biochemical reactions involve two or three phases. For example, aerobic fermentation involves gas (air), liquid (water and dissolved nutrients), and solid (cells), as described in the "Biocatalysis" subsection above. Bioreactions convert feeds called *substrates* into more *cells* or *biomass* (cell growth), proteins, and *metabolic products*. Any of these can be the desired product in a commercial *fermentation*. For instance, methane is converted to biomass in a commercial process to supply fish meal to the fish farming industry. Ethanol, a metabolic product used in transportation fuels, is obtained by fermentation of corn-based or sugar-cane-based sugars. There is a substantial effort to develop genetically modified biocatalysts that produce a desired metabolite at high yield.

Bioreactions follow the same general laws that govern conventional chemical reactions, but the complexity of the mechanism is higher due to the close coupling of bioreactions and *enzymes* that are turned on (*expressed*) or off (*repressed*) by the cell depending on the conditions in the fermenter and in the cell. Thus the rate expression (7-92) can mainly be used to design bioreaction processes when the culture is in *balanced growth*, i.e., for steady-state cultivations or batch growth for as long as the substrate concentration is much higher than  $C_s$ . After a sudden process upset (e.g., a sudden change in substrate concentration or pH), the *control network* of the cell that lies under the *mass flow network* is activated, and dramatic changes in the kinetics of product formation can occur. Table 7-9 summarizes key differences between biochemical and conventional chemical systems [see, e.g., Leib, Pereira, and Villadsen, "Bioreactors, A Chemical Engineering Perspective," *Chem. Eng. Sci.* **56**: 5485–5497 (2001)].

**TABLE 7-9 Biological versus Chemical Systems**

- There is tighter control on conditions (e.g., pH, temperature, substrate and product concentrations, dissolved  $O_2$  concentration, avoidance of contamination by foreign organisms).
- Pathways can be turned on/off by the microorganism through expression of certain enzymes depending on the substrate type and concentration and operating conditions, leading to a richness of behavior unparalleled in chemical systems.
- The global stoichiometry changes with operating conditions and feed composition; kinetics and stoichiometry obtained from steady-state (chemostat) data cannot be used reliably over a wide range of conditions, unless fundamental models are employed.
- Long-term adaptations (mutations) may occur in response to environment changes that can alter completely the product distribution.
- Only the substrates that maximize biomass growth are utilized even in the presence of multiple substrates.
- Cell energy balance requirements pose additional constraints on the stoichiometry that can make it very difficult to predict flux limitations.

TABLE 7-10 Hierarchy of Kinetic Models in Biological Systems

- Stoichiometric black box models (similar to a single global chemical reaction) represent the biochemistry by a single global reaction with fixed stoichiometric or *yield coefficients* (limited to a narrow range of conditions). Black box models can be used over a wider range of conditions by establishing different sets of yield coefficient for different conditions. These are also needed to establish the quantitative amounts of various nutrients needed for the completion of the bioreaction.
- Unstructured models view the cell as a single component interacting with the fermentation medium, and each bioreaction is considered to be a global reaction, with a corresponding empirical rate expression.
- Structured models include information on individual reactions or groups of reactions occurring in the cell, and cell components such as DNA, RNA, and proteins are included in addition to the primary metabolites and substrates (see, e.g., the active cell model of Nielsen and Villadsen, *Bioreaction Engineering Principles*, 2d ed., Kluwer Academic/Plenum Press, 2003).
- Fundamental models include cell dimensions, transport of substrates and metabolites across the cell membrane, and the elementary cell bioreaction steps and their corresponding enzyme induction mechanism. In recent years further kinetic steps have been added to the above models which are based on the conversion of substrates to metabolites. Thus the kinetics of protein synthesis by *transcription* and *translation* from the *genome* add much further complexity to cell kinetics.

The network of bioreactions is called the *metabolic network*, the series of consecutive steps between key intermediates in the network are called *metabolic pathways*, and the determination of the mechanism and kinetics is called *metabolic flux analysis*. As for chemical systems, there are several levels of mechanistic and kinetic representation and analysis, listed in order of increasing complexity in Table 7-10.

Additional complexity can be included through cell population balances that account for the distribution of cell generation present in the fermenter through use of stochastic models. In this section we limit the discussion to simple black box and unstructured models. For more details on bioreaction systems, see, e.g., Nielsen, Villadsen, and Liden, *Bioreaction Engineering Principles*, 2d ed., Kluwer, Academic/Plenum Press, 2003; Bailey and Ollis, *Biochemical Engineering Fundamentals*, 2d ed., McGraw-Hill, 1986; Blanch and Clark, *Biochemical Engineering*, Marcel Dekker, 1997; and Sec. 19.

**Mechanism** Stoichiometric balances are done on a C atom basis called *C-moles*, e.g., relative to the substrate (denoted by subscript *s*), and the corresponding stoichiometric coefficients  $Y_{si}$  (based on C-mole of the primary substrate) are called *yield coefficients*. For instance,

Here the reactants (substrates) are glucose ( $\text{CH}_2\text{O}$ ),  $\text{O}_2$ ,  $\text{NH}_3$ , and a sulfur-providing nutrient  $\text{S}_1$ , and the products are biomass X,  $\text{CO}_2$ , metabolic product  $\text{P}_1$ , and  $\text{H}_2\text{O}$ .

The products of bioreactions can be reduced or oxidized, and all feasible pathways have to be *redox neutral*. There are several cofactors that transfer redox power in a pathway or between pathways, each equivalent to the reducing power of a molecule of  $\text{H}_2$ , e.g., nicotinamide adenine dinucleotide (NADH), and these have to be included in the stoichiometric balances as H equivalents through redox balancing. For instance, for the reaction of glucose to glycerol ( $\text{CH}_3\text{O}$ ),  $\frac{1}{3}$  NADH equivalent is consumed:

The stoichiometry in the biochemical literature often does not show  $\text{H}_2\text{O}$  produced by the reaction; however, for complete elemental balance, water has to be included, and this is easily done once an  $\text{O}_2$  requirement has been determined based on a redox balance. Likewise for simplicity, the other form of the cofactor [e.g., the oxidized form of the cofactor NADH in Eq. (7-148)] is usually left out. In

addition to C balances, for aerobic systems cell respiration has to be accounted for as well through a stoichiometric equation:

The associated free energy produced or consumed in each reaction is captured in units of adenosine triphosphate (ATP). The ATP stoichiometry is usually obtained from biochemical tables since the energy has to be also balanced for the cell. Thus for Eq. (7-148) the stoichiometric ATP requirement to convert one C-mole of glucose to one C-mole of glycerol is  $\frac{1}{3}$ . In calculations of the carbon flux distribution in different pathways this ATP requirement has to be added on the left-hand side of the equation. Again the other form of the cofactor ATP is usually left out to simplify the reaction equation.

There are several metabolic pathways that are repeated for many living cells, and these are split into two: *catabolic* or energy-producing and *anabolic* or energy-consuming, the later producing building blocks such as amino acids and the resulting macromolecules such as proteins. Of course the energy produced in catabolic steps has to be balanced by the energy consumed in anabolic steps. Catabolic pathways include the well-studied *glycolysis*, *TCA cycle*, *oxidative phosphorylation*, and *fermentative pathways*. For more details see Stephanopoulos, Aristidou, and Nielsen, *Metabolic Engineering: Principles and Methodologies*, Academic Press, 1998; and Nielsen, Villadsen, and Liden, *Bioreaction Engineering Principles*, 2d ed., Kluwer, Academic/Plenum Press, 2003; Bailey and Ollis, *Biochemical Engineering Fundamentals*, 2d ed., McGraw-Hill, 1986.

**Monod-Type Empirical Kinetics** Many bioreactions show increased biomass growth rate with increasing substrate concentration at low substrate concentration for the limiting substrate, but no effect of substrate concentration at high concentrations. This behavior can be represented by the Monod equation (7-92). Additional variations on the Monod equation are briefly illustrated below. For two essential substrates the Monod equation can be modified as

$$\mu = \frac{\mu_{\max}C_{s1}C_{s2}}{(K_{s1} + C_{s2})(K_{s2} + C_{s2})} \quad (7-150)$$

This type of rate expression is often used in models for water treatment, and many environmental factors can be included (the effect of, e.g., phosphate, ammonia, volatile fatty acids, etc.). The correlation between parameters in such complicated models is, however, severe, and very often a simple Monod model (7-92) with only one limiting substrate is sufficient.

When *substrate inhibition* occurs,

$$\mu = \frac{\mu_{\max}C_s}{K_s + C_s + K_i/C_s^2} \quad (7-151)$$

$\text{O}_2$  is typically a substrate that in high concentrations leads to substrate inhibition, but a high concentration of the carbon source can also be inhibiting (e.g., in bioremediation of toxic waste a high concentration of the organic substrate can well lead to severe inhibition or death of the microorganism).

When *product inhibition* is present,

$$\mu = \frac{\mu_{\max}C_s}{K_s + C_s} \left( 1 - \frac{C_p}{C_{p\max}} \right) \quad (7-152)$$

Here the typical example is the inhibitor effect of ethanol on yeast growth. Considerable efforts are made by the biocompanies to develop yeast strains that are tolerant to high ethanol concentrations since this will give considerable savings in, e.g., production of biofuel by fermentation.

The various component reaction rates for a single reaction can be related to the growth rate by using the stoichiometric (yield) coefficients, e.g., from Eq. (7-147):

$$r_i = Y_{si}\mu C_x = \frac{Y_{si}}{Y_{sx}}\mu C_x \quad (7-153)$$

## 7-32 REACTION KINETICS

**Chemostat with Empirical Kinetics** Using the CSTR equation (7-54) for a constant-volume single reaction [Eq. (7-147)], the substrate, biomass, and product material balances are

$$\begin{aligned} \frac{1}{Y_{sx}} \mu C_x + D(C_{s0} - C_s) &= 0 \\ \mu C_x - DC_x &= 0 \rightarrow D = \mu \\ \frac{Y_{sp}}{Y_{sx}} \mu C_x - DC_p &= 0 \end{aligned} \quad (7-154)$$

Here  $C_{s0}$  is the feed substrate concentration, and  $D$  is the *dilution rate*, which at steady-state constant volume is equal to both the feed and effluent volumetric flow rates and to the specific growth rate. The effluent concentrations of substrate, biomass, and products can be calculated by using a suitable expression for the specific growth rate  $\mu$  such as one of the relevant variants of the Monod kinetics described above.

### ELECTROCHEMICAL REACTIONS

Electrochemical reactions involve coupling between chemical reactions and electric charge transfer and may have two or three phases, for instance, a gas (e.g.,  $H_2$  or  $O_2$  evolved at the electrodes or fed as reactants), a liquid (the electrolyte solution), and solids (electrodes). Electrocatalysts may be employed to enhance the reaction for a particular desired product. Hence, electrochemical reactions are heterogeneous reactions that occur at the surface of electrodes and involve the transfer of charge in the form of electrons as part of a chemical reaction. The electrochemical reaction can produce a chemical change by passing an electric current through the system (e.g., electrolysis), or reversely a chemical change can produce electric energy (e.g., using a battery or fuel cell to power an appliance). There are a variety of practical electrochemical reactions, some occurring naturally, such as corrosion, and others used in production of chemicals (e.g., the decomposition of HCl to produce  $Cl_2$  and  $H_2$ , the production of caustic soda and chlorine, the smelting of aluminum), electroplating, and energy generation (e.g., fuel cells and photovoltaics). Electrochemical reactions are reversible and can be generally written as a *reduction-oxidation (redox)* couple:

where  $O$  is an oxidized and  $R$  is a reduced species. For instance, the corrosion process includes oxidation at the *anode*:

and reduction at the *cathode*:

The overall electrochemical reaction is the stoichiometric sum of the anode and cathode reactions:

The anode and cathode reactions are close coupled in that the electric charge is conserved; therefore, the overall production rate is a direct function of the electric charge passed per unit time, the electric current  $I$ .

For references on electrochemical reaction kinetics and mechanism, see, e.g., Newman and Thomas-Alvea, *Electrochemical Systems*, 3d ed., Wiley Interscience, 2004; Bard and Faulkner, *Electrochemical Methods: Fundamentals and Applications*, 2d ed., Wiley, 2001; Bethune and Swendeman, "Table of Electrode Potentials and Temperature Coefficients," *Encyclopedia of Electrochemistry*, Van Nostrand Reinhold, New York 1964, pp. 414–424; and Bethune and Swendeman, *Standard Aqueous Electrode Potentials and Temperature Coefficients*, C. A. Hampel Publisher, 1964.

*Faraday's law* relates the charge transferred by ions in the electrolyte and electrons in the external circuit, to the moles of chemical species reacted (Newman and Thomas-Alvea, *Electrochemical Systems*, 3d ed., Wiley Interscience, 2004):

$$\begin{aligned} Q &= nmF & F &= 96,485 \text{ C/equiv} \\ I &= \frac{Q}{t} = \frac{\text{charge}}{\text{time}} & A & \end{aligned} \quad (7-155)$$

where  $n$  is the number of equivalents per mole,  $m$  is the number of moles,  $F$  is the Faraday constant,  $Q$  is the charge, and  $t$  is time. The total current passed may represent several parallel electrochemical reactions; therefore, we designate a current efficiency for each chemical species. The chemical species production rate (mass/time) is related to the total current passed  $I$ , the species *current efficiency*  $\epsilon_{\text{current},i}$ , and the molecular weight of the chemical species  $MW_i$ :

$$\begin{aligned} \dot{m} &= \frac{I \times \epsilon_{\text{current},i} \times MW_i}{nF} = \frac{\text{mass}}{\text{time}} \\ j &= \frac{\text{current}}{\text{area}} = \frac{I}{A_{\text{projected}}} \end{aligned} \quad (7-156)$$

Since electrochemical reactions are heterogeneous at electrode surfaces, the current  $I$  is generally normalized by dividing it by the geometric or projected area of the electrode, resulting in the quantity known as the *current density*  $j$ , in units of  $kA/m^2$ .

The overall electrochemical cell *equilibrium potential*  $E^\circ_{\text{cell}}$ , as measured between the cathode and the anode, is related to the Gibbs free energy change for the overall electrochemical reaction:

$$\begin{aligned} \Delta G^\circ &= \Delta H^\circ - T \Delta S^\circ = -nFE^\circ_{\text{cell}} \\ E^\circ_{\text{cell}} &= -\frac{\Delta G^\circ}{nF} = E^\circ_{\text{cathode}} - E^\circ_{\text{anode}} \end{aligned} \quad (7-157)$$

Each electrode reaction, anode and cathode, or half-cell reaction has an associated energy level or electrical potential (volts) associated with it. Values of the standard equilibrium electrode reduction potentials  $E^\circ$  at unit activity and  $25^\circ\text{C}$  may be obtained from the literature (de Bethune and Swendeman Loud, *Encyclopedia of Electrochemistry*, Van Nostrand Reinhold, 1964). The overall electrochemical cell *equilibrium potential* either can be obtained from  $\Delta G$  values or is equal to the cathode half-cell potential minus the anode half-cell potential, as shown above.

The *Nernst equation* allows one to calculate the *equilibrium potential*  $E^{\text{eq}}$  when the activity of the reactants or products is not at unity:

$$\begin{aligned} \sum_i \nu_i M_i^{\nu_i} &\rightarrow ne^- \\ E^{\text{eq}} &= E^\circ - \frac{RT}{nF} \ln(\Pi a_i^{\nu_i}) \\ \left( \frac{\partial E}{\partial T} \right)_p &= \frac{\Delta S}{nF} \end{aligned} \quad (7-158)$$

where  $\nu_i$  is the stoichiometric coefficient of chemical species  $i$  (positive for products; negative for reactants),  $M_i$  is the symbol for species  $i$ ,  $n_i$  is the charge number of the species,  $a_i$  is the activity of the chemical species,  $E$  is the *formal potential*, and  $\Pi$  represents the product of all respective activities raised to their stoichiometric powers as required by the reaction. Please note that if the value of the equilibrium potential is desired at another temperature,  $E^\circ$  must also be evaluated at the new temperature as indicated.

**Kinetic Control** In 1905, Julius Tafel experimentally observed that when mass transport was not limiting, the *current density*  $j$  of electrochemical reactions exhibited the following behavior:

$$j = a' e^{\eta_{\text{act}}/b'} \quad \text{or} \quad \eta_{\text{act}} = a + b \log j$$

where the quantity  $\eta_{\text{act}}$  is known as the *activation overpotential*  $E - E^{\text{eq}}$ , and is the difference between the actual electrode potential

$E$  and the reversible equilibrium potential of the electrochemical reaction  $E^{eq}$ . Thus the driving force for the electrochemical reaction is not the absolute potential; it is the activation overpotential  $\eta_{act}$ .

This relationship between the current density and activation overpotential has been further developed and resulted in the Butler-Volmer equation:

$$r = \frac{j}{nF} = k_f C_o - k_r C_r \quad j = j_0 (e^{-(\alpha_a F/RT)\eta_{act}} - e^{[(1-\alpha_c)F/RT]\eta_{act}})$$

$$\eta_{act} = E - E^{eq} \quad (7-159)$$

Here the reaction rate  $r$  is defined per unit electrode area, moles per area per time,  $j_0$  is the *equilibrium exchange current* when  $E = E^{eq}$ ,  $\eta_{act}$  is the *activation overpotential*, and  $\alpha$  is the *transfer coefficient*. For large activation overpotentials, the *Tafel empirical equation* applies:

$$\eta_{act} = a + b \log j \quad \text{for } \eta_{act} > 100 \text{ mV, } b = \text{Tafel slope} \quad (7-160)$$

For small activation overpotentials, linearization gives

$$j = j_0 \frac{nF}{RT} \eta_{act} \quad (7-161)$$

**Mass-Transfer Control** The surface concentration at the electrodes differs significantly from the bulk electrolyte concentration. The Nernst equation applies to the surface concentrations (or activities in case of nonideal solutions):

$$E^{eq} = E^o - \frac{RT}{nF} \ln(\Pi a_{i,surf}^{\nu_i}) \quad (7-162)$$

## DETERMINATION OF MECHANISM AND KINETICS

Laboratory data are the predominant source for reaction mechanism and kinetics in industrial practice. However, often laboratory data intended for scoping and demonstration studies rather than for kinetic evaluation have to be used, thus reducing the effectiveness and accuracy of the resulting kinetic model. The following are the steps required to obtain kinetics from laboratory data:

1. Develop initial guesses on mechanism, reaction time scale, and potential kinetic models from the literature, scoping experiments, similar chemistries, and computational chemistry calculations, when possible.

2. Select a suitable laboratory reactor type and scale, and analytical tools for kinetic measurements.

3. Develop a priori factorial experimental design or sequential experimental design.

4. When possible, provide ideal reactor conditions, e.g., good mechanical agitation in batch and CSTR, high velocity flow in PFR.

5. Estimate the limiting diffusion-reaction regimes under the prevailing lab reactor conditions for heterogeneous reactions, and use the appropriate lab reactor model. When possible, operate the reactor under kinetic control.

6. Discriminate between competing mechanisms and kinetic rates by forcing maximum differentiation between competing hypotheses through the experimental design, and by obtaining the best fit of the kinetic data to the proposed kinetic forms.

### LABORATORY REACTORS

Selection of the laboratory reactor type and size, and associated feed and product handling, control, and analytical schemes depends on the type of reaction, reaction time scales, and type of analytical methods required. The criteria for selection include equipment cost, ease of operation, ease of data analysis, accuracy, versatility, temperature uniformity, and controllability, suitability for mixed phases, and scale-up

If mass transfer is limiting, then a *limiting current* is obtained for each chemical species  $i$ :

$$j_{i,lim} = \frac{nFD_i C_i}{\delta} = nFk_{L,i} C_i \quad (7-163)$$

where  $D_i$  is the diffusion coefficient,  $\delta$  is the boundary layer thickness, and  $k_{L,i}$  is the mass-transfer coefficient of species  $i$ . The effect of mass transfer is included as follows:

$$j = j_0 \left[ \left( 1 - \frac{j}{j_{a,lim}} \right) e^{-(\alpha_a F/RT)\eta_{act}} - \left( 1 - \frac{j}{j_{c,lim}} \right) e^{[(1-\alpha_c)F/RT]\eta_{act}} \right]$$

$$\frac{C_{i,surf}}{C_i} = \left( 1 - \frac{j}{j_{i,lim}} \right) \quad i = o, r \quad (7-164)$$

**Ohmic Control** The overall electrochemical reactor cell voltage may be dependent on the kinetic and mass-transfer aspects of the electrochemical reactions; however, a third factor is the potential lost within the electrolyte as current is passing through this phase. The potential drops may become dominant and limit the electrochemical reactions requiring an external potential to be applied to drive the reactions or significantly lower the delivered electrical potential in power generation applications such as batteries and fuel cells.

**Multiple Reactions** With multiple reactions, the total current is the sum of the currents from the individual reactions with anodic currents positive and cathodic currents negative. This is called the *mixed potential principle*. For more details see Bard and Faulkner, *Electrochemical Methods: Fundamentals and Applications*, 2d ed., Wiley, 2001.

feasibility. Many configurations of laboratory reactors have been employed. Rase (*Chemical Reactor Design for Process Plants*, Wiley, 1977) and Shah (*Gas-Liquid-Solid Reactor Design*, McGraw-Hill, 1979) each have about 25 sketches, and Shah's bibliography has 145 items classified into 22 categories of reactor types. Jankowski et al. [*Chemische Technik* 30: 441-446 (1978)] illustrate 25 different kinds of gradientless laboratory reactors for use with solid catalysts.

Laboratory reactors are of two main types:

1. Reactors used to obtain fundamental data on intrinsic chemical rates free of mass-transfer resistances or other complications. Some of the gas-liquid lab reactors, for instance, employ known interfacial areas, thus avoiding the uncertainty regarding the area for gas to liquid mass transfer. When ideal behavior cannot be achieved, intrinsic kinetic estimates need to account for mass- and heat-transfer effects.

2. Reactors used to obtain scale-up data due to their similarity to the reactor intended for the pilot or commercial plant scale. How to scale down from the conceptual commercial or pilot scale to lab scale is a difficult problem in itself, and it is not possible to maintain all key features while scaling down.

The first type is often the preferred one—once the intrinsic kinetics are obtained at “ideal” lab conditions, scale-up is done by using models or correlations that describe large-scale reactor hydrodynamics coupled with the intrinsic kinetics. However, in some cases ideal conditions cannot be achieved, and the laboratory reactor has to be adequately modeled to account for mass and heat transfer and non-ideal mixing effects to enable extraction of intrinsic kinetics. In addition, with homogeneous reactions, attention must be given to prevent wall-catalyzed reactions, which can result in observed kinetics that are fundamentally different from intrinsic homogeneous kinetics. This is a problem for scale-up, due to the high surface/volume ratio in small reactors versus the low surface/volume ratio in large-scale systems, resulting in widely different contributions of wall effects at different scales. Similar issues arise in bioreactors with the potential of

## 7-34 REACTION KINETICS

undesirable wall growth of the biocatalyst cells masking the homogeneous growth kinetics. In catalytic reactions certain reactor configurations may enhance undesirable homogeneous reactions, and the importance of these reactions may be different at larger scale, causing potential scale-up pitfalls.

The reaction rate is expressed in terms of chemical compositions of the reacting species, so ultimately the variation of composition with time or space must be found. The composition is determined in terms of a property that is measured by some instrument and calibrated. Among the measures that have been used are titration, pressure, refractive index, density, chromatography, spectrometry, polarimetry, conductimetry, absorbance, and magnetic resonance. Therefore, batch or semibatch data are converted to composition as a function of time ( $C, t$ ), or to composition and temperature as functions of time ( $C, T, t$ ), to prepare for kinetic analysis. In a steady CSTR and PFR, the rate and compositions in the effluent are observed as a function of residence time.

When a reaction has many reactive species (which may be the case even for apparently simple processes such as pyrolysis of ethane or synthesis of methanol), a factorial or sequential experimental design should be developed and the data can be subjected to a *response surface analysis* (Box, Hunter, and Hunter, *Statistics for Experimenters*, 2d ed., Wiley Interscience, 2005; Davies, *Design and Analysis of Industrial Experiments*, Oliver & Boyd, 1954). This can result in a black box correlation or statistical model, such as a quadratic (limited to first- and second-order effects) for the variables  $x_1, x_2$ , and  $x_3$ :

$$r = k_1x_1 + k_2x_2 + k_3x_3 + k_{12}x_1x_2 + k_{13}x_1x_3 + k_{23}x_2x_3$$

Analysis of such statistical correlations may reveal the significant variables and interactions and may suggest potential mechanisms and kinetic models, say, of the Langmuir-Hinshelwood type, that could be analyzed in greater detail by a regression process. The variables  $x_i$  could be various parameters of heterogeneous processes as well as concentrations. An application of this method to isomerization of *n*-pentane is given by Kittrel and Erjavec [*Ind. Eng. Chem. Proc. Des. Dev.* 7: 321 (1968)].

Table 7-11 summarizes laboratory reactor types that approach the three ideal concepts BR, CSTR and PFR, classified according to reaction types.

**TABLE 7-11 Laboratory Reactors**

| Reaction               | Reactor   |
|------------------------|---|

| Gas-liquid             | CSTR with jacketed cooling/heating<br>Fixed interface CSTR<br>Wetted wall<br>Laminar jet  |
| Gas-liquid-solid       | Slurry CSTR with jacketed cooling/heating<br>Packed bed with downflow, upflow, or countercurrent  |
| Solid-solid            | Packed tube in furnace  |

For instance, Fig. 7-17 summarizes laboratory reactor types and hydrodynamics for gas-liquid reactions.

**Batch Reactors** In the simplest kind of investigation, reactants can be loaded into a number of sealed tubes, kept in a thermostatic bath for various periods, shaken mechanically to maintain uniform composition, and analyzed. In terms of cost and versatility, the stirred batch reactor is the unit of choice for homogeneous or heterogeneous slurry reactions including gas-liquid and gas-liquid-solid systems. For multiphase systems the reactants can be semibatch or continuous. The BR is especially suited to reactions with half-lives in excess of 10 min. Samples are taken at time intervals, and the reaction is stopped by cooling, by dilution, or by destroying a residual reactant such as an acid or base; analysis can then be made at a later time. Analytic methods that do not necessitate termination of reaction include noninvasive measurements of (1) the amount of gas produced, (2) the gas pressure in a constant-volume vessel, (3) absorption of light, (4) electrical or thermal conductivity, (5) polarography, (6) viscosity of polymerization, (7) pH and DO probes, and so on. Operation may be isothermal, with the important effect of temperature determined from several isothermal runs, or the composition and temperature may be recorded simultaneously and the

**FIG. 7-17** Principal types of laboratory reactors for gas-liquid reactions. [From Fig. 8 in J. C. Charpentier, "Mass Transfer Rates in Gas-Liquid Absorbers and Reactors," in Drew et al. (eds.), *Advances in Chemical Engineering*, vol. 11, Academic Press, 1981.]

data regressed. On the laboratory scale, it is essential to ensure that a BR is stirred to uniform composition, and for critical cases such as high viscosities this should be checked with tracer tests.

**Flow Reactors** CSTRs and other devices that require flow control are more expensive and difficult to operate. However, CSTRs and PFRs are the preferred laboratory reactors for steady operation. One of the benefits of CSTRs is their isothermicity and the fact that their mathematical representation is algebraic, involving no differential equations, thus making data analysis simpler. For laboratory research purposes, CSTRs are considered feasible for holding times of 1 to 4000 s, reactor volumes of 2 to 1000 cm<sup>3</sup> (0.122 to 61 in<sup>3</sup>), and flow rates of 0.1 to 2.0 cm<sup>3</sup>/s. Fast reactions and those in the gas phase are generally done in tubular flow reactors, just as they are often done on the commercial scale. Usually it is not possible to measure compositions along a PFR, although temperatures can be measured using a thermowell with fixed or mobile thermocouple bundle. PFRs can be kept at nearly constant temperatures; small-diameter tubes immersed in a fluidized sand bed or molten salt can hold quite constant temperatures of a few hundred degrees. Other PFRs are operated at near adiabatic conditions by providing dual radial temperature control to minimize the radial heat flux, with multiple axial zones. A recycle unit can be operated as a differential reactor with arbitrarily small conversion and temperature change. Test work in a tubular flow unit may be desirable if the intended commercial unit is of that type.

**Multiphase Reactors** Reactions between gas-liquid, liquid-liquid, and gas-liquid-solid phases are often tested in CSTRs. Other laboratory types are suggested by the commercial units depicted in appropriate sketches in Sec. 19 and in Fig. 7-17 [Charpentier, *Mass Transfer Rates in Gas-Liquid Absorbers and Reactors*, in Drew et al. (eds.), *Advances in Chemical Engineering*, vol. 11, Academic Press, 1981]. Liquids can be reacted with gases of low solubilities in stirred vessels, with the liquid charged first and the gas fed continuously at the rate of reaction or dissolution. Some of these reactors are designed to have known interfacial areas. Most equipment for gas absorption without reaction is adaptable to absorption with reaction. The many types of equipment for liquid-liquid extraction also are adaptable to reactions of immiscible liquid phases.

**Solid Catalysts** Processes with solid catalysts are affected by diffusion of heat and mass (1) within the pores of the pellet, (2) between the fluid and the particle, and (3) axially and radially within the packed bed. Criteria in terms of various dimensionless groups have been developed to tell when these effects are appreciable, and some of these were discussed above. For more details see Mears [*Ind. Eng. Chem. Proc. Des. Devel.* **10**: 541–547 (1971); *Ind. Eng. Chem. Fund.* **15**: 20–23 (1976)] and Satterfield (*Heterogeneous Catalysis in Practice*, McGraw-Hill, 1991, p. 491). For catalytic investigations, the rotating basket or fixed basket with internal recirculation is the standard device, usually more convenient and less expensive than equipment with external recirculation. In the fixed-basket type, an internal recirculation rate of 10 to 15 or so times the feed rate effectively eliminates external diffusional resistance, and temperature gradients (see, e.g., Berty, *Experiments in Catalytic Reaction Engineering*, Elsevier, 1999). A unit holding 50 cm<sup>3</sup> (3.05 in<sup>3</sup>) of catalyst can operate up to 800 K (1440°R) and 50 bar (725 psi). When deactivation occurs rapidly (in a few seconds during catalytic cracking, for instance), the fresh activity can be maintained with a transport reactor through which both reactants and fresh catalyst flow without slip and with short contact time. Since catalysts often are sensitive to traces of impurities, the time deactivation of the catalyst usually can be evaluated only with commercial feedstock. Physical properties of catalysts also may need to be checked periodically, including pellet size, specific surface, porosity, pore size and size distribution, effective diffusivity, and active metals content and dispersion. The effectiveness of a porous catalyst is found by measuring conversions with successively smaller pellets until no further change occurs. These topics are touched on by Satterfield (*Heterogeneous Catalysis in Industrial Practice*, McGraw-Hill, 1991).

To determine the deactivation kinetics, long-term deactivation studies at constant conditions and at different temperatures are required. In some cases, accelerated aging can be induced to reduce the time required for the experimental work, by either increasing the feed flow

rate (if the deactivation is a result of feed or product poisoning) or increasing the temperature above the standard reaction temperature. These require a good understanding of how the higher-temperature or rate-accelerated deactivation correlates with deactivation at the operating reaction temperature and rate.

**Bioreactors** There are several types of laboratory bioreactors used with live organisms as biocatalysts:

1. Mechanically agitated batch/semibatch with pH control and nutrients or other species either fed at the start or added continuously based on a recipe or protocol.

2. CSTR to maintain a constant *dilution rate* (the feed rate). These require some means to separate the biocatalyst from the product and recycle to the reactor, such as centrifuge or microfiltration:

a. *Chemostat* controls the flow to maintain a constant fermentation volume.

b. *Turbidostat* controls the biomass or cells concentration.

c. *pH-auxostat* controls pH in the effluent (same as pH in reactor).

d. *Productostat* controls the effluent concentration of one of the metabolic products.

The preferred reactor for kinetics is the chemostat, but semibatch reactors are more often used owing to their simpler operation.

**Calorimetry** Another category of laboratory systems that can be used for kinetics includes *calorimeters*. These are primarily used to establish temperature effects and thermal runaway conditions, but can also be employed to determine reaction kinetics. Types of calorimeters are summarized in Table 7-12; for more details see Reid, "Differential Microcalorimeters," *J. Physics E: Scientific Instruments*, **9** (1976).

Additional methods of laboratory data acquisition are described in Masel, *Chemical Kinetics and Catalysis*, Wiley, 2001.

## KINETIC PARAMETERS

The kinetic parameters are constants that appear in the intrinsic kinetic rate expressions and are required to describe the rate of a reaction or reaction network. For instance, for the simple global *n*th-order reaction with Arrhenius temperature dependence:

The kinetic parameters are  $k_0$ ,  $E$ , and  $n$ , and knowledge of these parameters and the prevailing concentration and temperature fully determines the reaction rate.

For a more complex expression such as the Langmuir-Hinshelwood rate for gas reaction on heterogeneous catalyst surface with equilibrium adsorption of reactants *A* and *B* on two different sites and non-adsorbing products, Eq. (7-85) can be rewritten as

$$r = \frac{k_0 e^{-E/RT} P_a P_b}{(1 + K_{a0} e^{-E_a/RT})(1 + K_{b0} e^{-E_b/RT})} \quad (7-166)$$

and the kinetic parameters are  $k_0$ ,  $E$ ,  $K_{a0}$ ,  $E_{a0}$ ,  $K_{b0}$ , and  $E_{b0}$ .

A number of factors limit the accuracy with which parameters needed for the design of commercial equipment can be determined. The kinetic parameters may be affected by inaccurate accounting for laboratory reactor heat and mass transport, and hydrodynamics; correlations for these are typically determined under nonreacting conditions at ambient temperature and pressure and with nonreactive model fluids and may not be applicable or accurate at reaction conditions. Experimental uncertainty including errors in analysis, measurement,

and control is also a contributing factor (see, e.g., Hoffman, "Kinetic Data Analysis and Parameter Estimation," in de Lasa (ed.), *Chemical Reactor Design and Technology*, Martinus Nijhoff, 1986.

### DATA ANALYSIS METHODS

In this section we focus on the three main types of ideal reactors: BR, CSTR, and PFR. Laboratory data are usually in the form of concentrations or partial pressures versus batch time (batch reactors), concentrations or partial pressures versus distance from reactor inlet or residence time (PFR), or rates versus residence time (CSTR). Rates can also be calculated from batch and PFR data by differentiating the concentration versus time or distance data, usually by numerical curve fitting first. It follows that a general classification of experimental methods is based on whether the data measure rates directly (differential or direct method) or indirectly (integral of indirect method). Table 7-13 shows the pros and cons of these methods.

Some simple reaction kinetics are amenable to analytical solutions and graphical linearized analysis to calculate the kinetic parameters from rate data. More complex systems require numerical solution of nonlinear systems of differential and algebraic equations coupled with nonlinear parameter estimation or regression methods.

**Differential Data Analysis** As indicated above, the rates can be obtained either directly from differential CSTR data or by differentiation of integral data. A common way of evaluating the kinetic parameters is by rearrangement of the rate equation, to make it linear in parameters (or some transformation of parameters) where possible. For instance, using the simple  $n$ th-order reaction in Eq. (7-165) as an example, taking the natural logarithm of both sides of the equation results in a linear relationship between the variables  $\ln r$ ,  $1/T$ , and  $\ln C_a$ :

$$\ln r = \ln k_0 - \frac{E}{RT} + n \ln C_a \quad (7-167)$$

Multilinear regression can be used to find the constants  $k_0$ ,  $E$ , and  $n$ . For constant-temperature (isothermal) data, Eq. (7-167) can be simplified by using the Arrhenius form as

$$\ln r = \ln k + n \ln C_a \quad (7-168)$$

and the kinetic parameters  $n$  and  $k$  can be determined as the intercept and slope of the best straight-line fit to the data, respectively, as shown in Fig. 7-18.

The preexponential  $k_0$  and activation energy  $E$  can be obtained from multiple isothermal data sets at different temperatures by using the linearized form of the Arrhenius equation

$$\ln k = \ln k_0 - \frac{E}{RT} \quad (7-169)$$

as shown in Fig. 7-19.

**Integral Data Analysis** Integral data such as from batch and PFR relate concentration to time or distance. Integration of the BR equation for an  $n$ th-order homogeneous constant-volume reaction yields

**TABLE 7-13 Comparison of Direct and Indirect Methods**

| Direct method                                     | Indirect method  |
|---|--|
| Advantages  | Disadvantages  |
| Get rate equation directly                        | Must infer rate equation   |
| Easy to fit data to a rate law                    | Hard to analyze rate data  |
| High confidence on final rate equation            | Low confidence on final rate equation                            |
| Disadvantages                                     | Advantages   |
| Difficult experiment                              | Easier experiment  |
| Need many runs                                    | Can do a few runs and get important information                  |
| Not suitable for very fast or very slow reactions | Suitable for all reactions including very fast or very slow ones |

SOURCE: Masel, *Chemical Kinetics and Catalysis*, Wiley, 2001, Table 3.2.

**FIG. 7-18** Determination of the rate constant and reaction order.

**FIG. 7-19** Determination of the activation energy.

$$\ln \frac{C_{a0}}{C_a} = k\tau \quad \text{for } n = 1 \quad (7-170)$$

$$\left( \frac{C_{a0}}{C_a} \right)^{n-1} = 1 + k\tau(n-1)C_{a0}^{n-1} \quad \text{for } n \neq 1$$

For the first-order case, the rate constant  $k$  can be obtained directly from the slope of the graph of the left-hand side of Eq. (7-170) versus batch time, as shown in Fig. 7-20.

For orders other than first, plotting the natural log of Eq. (7-170) can at least indicate if the order is larger or smaller than 1, as shown in Fig. 7-21.

**The Half-Life Method** The half-life is the batch time required to get 50 percent conversion. For an  $n$ th-order reaction,

$$\tau_{1/2} = \frac{\ln 2}{k} \quad \text{for } n = 1 \quad (7-171)$$

$$\tau_{1/2} = \frac{2^{n-1} - 1}{(n-1)kC_{a0}^{n-1}} \quad \text{for } n \neq 1$$

**FIG. 7-20** Determination of first-order rate constant from integral data.

FIG. 7-21 Reaction behavior for  $n$ th-order reaction. (Masek, *Chemical Kinetics and Catalysis*, Wiley, 2001, Fig. 3.15.)

Thus for first-order reactions, the *half-life* is constant and independent of the initial reactant concentration and can be used directly to calculate the rate constant  $k$ . For non-first-order reactions, Eq. (7-171) can be linearized as follows:

$$\ln \tau_{1/2} = \ln \frac{2^{n-1} - 1}{(n-1)k} - (n-1) \ln C_{a0} \quad \text{for } n \neq 1 \quad (7-172)$$

The reaction order  $n$  can be obtained from the slope and the rate constant  $k$  from the intercept of the plot of Eq. (7-172), shown in Fig. 7-22.

**Complex Rate Equations** The examples above are for special cases amenable to simple treatment. Complex rate equations and reaction networks with complex kinetics require individual treatment, which often includes both numerical solvers for the differential and algebraic equations describing the laboratory reactor used to obtain the data and linear or nonlinear parameter estimation.

## PARAMETER ESTIMATION

The straightforward method to obtain kinetic parameters from data is the numerical fitting of the concentration data (e.g., from BR or PFR) to integral equations, or the rate data (e.g., from a CSTR or from differentiation of BR or PFR) to rate equations. This is done by parameter estimation methods described here. An excellent reference for experimental design and parameter estimation (illustrated for heterogeneous gas-solid reactions) is the review paper of Froment and Hosten, "Catalytic Kinetics—Modeling," in *Catalysis—Science and Technology*, Springer-Verlag, New York, 1981. Two previous papers devoted to this topic by Hofmann [in *Chemical Reaction Engineering*, ACS *Advances in Chemistry*, **109**: 519–534 (1972); in de Lasa (ed.),

FIG. 7-22 Determination of reaction order and rate constant from half-life data.

*Chemical Reactor Design and Technology*, Martinus Nijhoff, 1985, pp. 69–105] are also very useful. As indicated above, the acquisition of kinetic data and parameter estimation can be a complex endeavor. It includes statistical design of experiments, laboratory equipment, computer-based data acquisition, complex analytical methods, and statistical evaluation of the data.

**Regression** is the procedure used to estimate the kinetic parameters by fitting kinetic model predictions to experimental data. When the parameters can be made to appear linear in the kinetic model (through transformations, grouping of parameters, and rearrangement), the regression is linear, and an accurate fit to data can be obtained, provided the form of the kinetic model represents well the reaction kinetics and the data provide enough width in temperature, pressure, and composition for statistically significant estimates. Often such linearization is not possible.

**Linear Models in Parameters, Single Reaction** We adopt the terminology from Froment and Hosten, "Catalytic Kinetics—Modeling," in *Catalysis—Science and Technology*, Springer-Verlag, New York, 1981. For  $n$  observations (experiments) of the concentration vector  $y$  for a model linear in the parameter vector  $\beta$  of length  $p < n$ , the *residual error*  $\epsilon$  is the difference between the kinetic model-predicted values and the measured data values:

$$\epsilon = y - X\beta = y - \hat{y} \quad (7-173)$$

The linear model is represented as a linear transformation of the parameter vector  $\beta$  through the model matrix  $X$ . Estimates  $b$  of the true parameters  $\beta$  are obtained by minimizing the *objective function*  $S(\beta)$ , the *sum of squares of the residual errors*, while varying the values of the parameters:

$$S(\beta) = \epsilon^T \epsilon = \sum_{i=1}^n (y_i - \hat{y}_i)^2 \xrightarrow{\beta} \text{Min} \quad (7-174)$$

This linear optimization problem, subject to constraints on the possible values of the parameters (e.g., requiring positive preexponentials, activation energies, etc.) can be solved to give the estimated parameters:

$$b = (X^T X)^{-1} X^T y \quad (7-175)$$

When the error is *normally distributed* and has zero mean and variance  $\sigma^2$ , then the *variance-covariance matrix*  $V(b)$  is defined as

$$V(b) = (X^T X)^{-1} \sigma^2 \quad (7-176)$$

An estimate for  $\sigma^2$ , denoted  $s^2$ , is

$$s^2 = \frac{\sum_{i=1}^n (y_i - \hat{y}_i)^2}{n - p} \quad (7-177)$$

When  $V(b)$  is known from experimental observations, a *weighted objective function* should be used for optimization of the objective function:

$$S(\beta) = \epsilon^T V^{-1} \epsilon \xrightarrow{\beta} \text{Min} \quad (7-178)$$

and the estimates  $b$  are obtained as

$$b = (X^T V^{-1} X)^{-1} X^T V^{-1} y \quad (7-179)$$

The parameter fit is adequate if the *F test* is satisfied, that is,  $F_c$ , the calculated  $F$ , is larger than the tabulated statistical one at the *confidence level* of  $1 - \alpha$ :

$$F_c = \frac{\frac{\text{LFSS}}{n - p - n_e + 1}}{\frac{\text{PESS}}{n_e - 1}} \geq F(n - p - n_e + 1, n_e - 1; 1 - \alpha) \quad (7-180)$$

## 7-38 REACTION KINETICS

$$\text{LFSS} = \sum_{i=1}^n (y_i - \hat{y}_i)^2 - \sum_{i=1}^{ne} (y_i - \bar{y}_i)^2 \quad \text{PESS} = \sum_{i=1}^{ne} (y_i - \bar{y}_i)^2$$

Here  $\bar{y}_i$  are the averaged values of the data for replicates. Equation (7-180) is valid if there are  $n$  replicate experiments and the pure error sum of squares (PESS) is known. Without replicates,

$$F_c = \frac{\frac{\text{RgSS}}{p}}{\frac{\text{RSS}}{n-p}} \geq F(p, n-p; 1-\alpha) \quad \text{RgSS} = \sum_{i=1}^n \hat{y}_i^2$$

$$\text{RSS} = \sum_{i=1}^n (y_i - \hat{y}_i)^2 \quad (7-181)$$

The bounds on the parameter estimates are given by the  $t$  statistics:

$$b_i - t\left(n-p; 1 - \frac{\alpha}{2}\right) \leq \beta_i \leq b_i + t\left(n-p; 1 - \frac{\alpha}{2}\right) \quad (7-182)$$

An example of a linear model in parameters is Eq. (7-167), where the parameters are  $\ln k_0$ ,  $E$ , and  $n$ , and the linear regression can be used directly to estimate these.

**Nonlinear Models in Parameters, Single Reaction** In practice, the parameters appear often in nonlinear form in the rate expressions, requiring nonlinear regression. Nonlinear regression does not guarantee optimal parameter estimates even if the kinetic model adequately represents the true kinetics and the data width is adequate. Further, the statistical tests of model adequacy apply rigorously only to models linear in parameters, and can only be considered approximate for nonlinear models.

For a general nonlinear model  $f(x, \beta)$ , where  $x$  is the vector of the independent model variables and  $\beta$  is the vector of parameters,

$$\varepsilon = y - f(x, \beta) \quad (7-183)$$

An example of a model nonlinear in parameters is Eq. (7-166). Here it is not possible through any number of transformations to obtain a linear form in all the parameters  $k_0$ ,  $E$ ,  $K_{ab}$ ,  $E_{aa}$ ,  $K_{bb}$ ,  $E_{ab}$ . Note that for some Langmuir-Hinshelwood rate expressions it is possible to linearize the model in parameters at isothermal conditions and obtain the kinetic constants for each temperature, followed by Arrhenius-type plots to obtain activation energies (see, e.g., Churchill, *The Interpretation and Use of Rate Data: The Rate Concept*, McGraw-Hill, 1974).

Minimization of the sum of squares of residuals does not result in a closed form for nonlinear parameter estimates as for the linear case; rather it requires an iterative numerical solution, and having a reasonable initial estimate for the parameter values and their feasible ranges is critical for success. Also, the minima in the residual sum of squares are local and not global. To obtain global minima that better represent the kinetics over a wide range of conditions, parameter estimation has to be repeated with a wide range of initial parameter guesses to increase the chance of reaching the global minimum. The nonlinear regression procedure typically involves a *steepest descent* optimization search combined with *Newton's linearization* method when a minimum is approached, enhancing the convergence speed [e.g., the *Marquardt-Levenberg* or *Newton-Gauss* method; Marquardt, *J. Soc. Ind. Appl. Math.* **2**: 431 (1963)].

An integral part of the parameter estimation methodology is *mechanism discrimination*, i.e., selection of the best mechanism that would result in the best kinetic model. Nonlinear parameter estimation is an extensive topic and will not be further discussed here. For more details see Froment and Hosten, "Catalytic Kinetics—Modeling," in *Catalysis—Science and Technology*, Springer-Verlag, New York, 1981.

**Network of Reactions** The statistical parameter estimation for multiple reactions is more complex than for a single reaction. As indicated before, a single reaction can be represented by a single con-

centration [e.g., Eq. 7-39]. With a network of reactions, there are a number of dependent variables equal to the number of stoichiometrically independent reactions, also called *responses*. In this case the objective function has to be modified. For details see Froment and Hosten, "Catalytic Kinetics—Modeling," in *Catalysis—Science and Technology*, Springer-Verlag, New York, 1981.

## THEORETICAL METHODS

**Prediction of Mechanism and Kinetics** Reaction mechanisms for a variety of reaction systems can be predicted to some extent by following a set of heuristic rules derived from experience with a wide range of chemistries. For instance, Masel, *Chemical Kinetics and Catalysis*, Wiley, 2001, chapter 5, enumerates the rules for gas-phase chain and nonchain reactions including limits on activation energies for various elementary steps. Other reaction systems such as ionic reactions, and reactions on metal and acid surfaces, are also discussed by Masel, although these mechanisms are not as well understood. Nevertheless, the rules can lead to computer-generated mechanisms for complex systems such as homogeneous gas-phase combustion and partial oxidation of methane and higher hydrocarbons. Developments in computational chemistry methods allow, in addition to the derivation of most probable elementary mechanisms, prediction of thermodynamic and kinetic reaction parameters for relatively small molecules in homogeneous gas-phase and liquid-phase reactions, and even for some heterogeneous catalytic systems. This is especially useful for complex kinetics where there is no easily discernible rate-determining step, and therefore no simple closed-form global reaction rate can be determined. In particular, estimating a large number of kinetic parameters from laboratory data requires a large number of experiments and use of intermediate reaction components that are not stable or not readily available. The nonlinear parameter estimation with many parameters is difficult, with no assurance that global minima are actually obtained. For such complex systems, computational chemistry estimates are an attractive starting point, requiring experimental validation.

Computational chemistry includes a wide range of methods of varying accuracy and complexity, summarized in Table 7-14. Many of these methods have been implemented as software packages that require high-speed supercomputers or parallel computers to solve realistic reactions. For more details on computational chemistry, see, e.g., Cramer, *Essentials of Computational Chemistry: Theories and Models*, 2d ed., Wiley, 2004.

**Lumping and Mechanism Reduction** It is often useful to reduce complex reaction networks to a smaller reaction set which still maintains the key features of the detailed reaction network but with a much smaller number of representative species, reactions, and kinetic parameters. Simple examples were already given above for reducing simple networks into global reactions through assumptions such as pseudo-steady state, rate-limiting step, and equilibrium reactions.

In general, *mechanism reduction* can only be used over a limited range of conditions for which the simplified system simulates the original complete reaction network. This reduces the number of kinetic parameters that have to be either estimated from data or calculated by

**TABLE 7-14 Computational Chemistry Methods**

using computational chemistry. The simplified system also reduces the computation load for reactor scale-up, design, and optimization.

A type of mechanism reduction called *lumping* is typically performed on a reaction network that consists of a large number of similar reactions occurring between similar species, such as homologous series or molecules having similar functional groups. Such situations occur, for instance, in the oil refining industry, examples including catalytic reforming, catalytic cracking, hydrocracking, and hydrotreating. Lumping is done by grouping similar species, or molecules with similar functional groups, into pseudo components called lumped species. The behavior of the lumped system depends on the initial composition, the distribution of the rate constants in the detailed system, and the form of the rate equation. The two main issues in lumping are

1. Determination of the lump structure that simulates the detailed system over the required range of conditions
2. Determination of the kinetics of the lumped system from general knowledge about the type of kinetics and the overall range of parameters of the detailed system

Lumping has been applied extensively to first-order reaction networks [e.g., Wei and Kuo, "A Lumping Analysis in Monomolecular Reaction Systems," *I&EC Fundamentals* **8**(1): 114–123 (1969); Golikeri and Luss, "Aggregation of Many Coupled Consecutive First Order Reactions," *Chem. Eng. Sci.* **29**: 845–855 (1974)]. For instance, it has been shown that a lumped reaction network of first-order reactions can behave under certain conditions as a global second-order reaction. Where analytical solutions were not available, others, such as Golikeri and Luss, "Aggregation of Many Coupled Consecutive First Order Reactions," *Chem. Eng. Sci.* **29**: 845–855 (1974), developed bounds that bracketed the behavior of the lump for first-order reactions as a function of the initial composition and the rate constant distribution. Lumping has not been applied as successfully to nonlinear or higher-order kinetics. More recent applications of lumping were published, including structure-oriented lumping that lumps similar structural groups, by Quann and Jaffe, "Building Useful Models of Complex Reaction Systems in Petroleum Refining," *Chem. Eng. Sci.* **51**(10): 1615–1635 (1996).

For other types of systems such as highly branched reaction networks for homogeneous gas-phase combustion and combined homogeneous and catalytic partial oxidation, mechanism reduction involves pruning branches and pathways of the reaction network that do not contribute significantly to the overall reaction. This pruning is done by using *sensitivity analysis*. See, e.g., Bui et al., "Hierarchical Reduced Models for Catalytic Combustion: H<sub>2</sub>/Air Mixtures near Platinum Surfaces," *Combustion Sci. Technol.* **129**(1–6):243–275 (1997).

**Multiple Steady States, Oscillations, and Chaotic Behavior**  
There are reaction systems whose steady-state behavior depends on

the initial or starting conditions; i.e., for different starting conditions, different steady states can be reached at the same final operating conditions. This behavior is called steady-state multiplicity and is often the result of the interaction of kinetic and transport phenomena having distinct time scales. For some cases, the cause of the multiplicity is entirely reaction-related, as shown below. Associated with steady-state multiplicity is hysteresis, and higher-order instabilities such as self-sustained oscillations and chaotic behavior. The existence of multiple steady states may be relevant to analysis of laboratory data, since faster of slower rates may be observed at the same conditions depending on how the lab reactor is started up.

For example, CO oxidation on heterogeneous Rh catalyst exhibits hysteresis and multiple steady states, and one of the explained causes is the existence of two crystal structures for Rh, each with a different reactivity (Masel, *Chemical Kinetics and Catalysis*, Wiley, 2001, p. 38).

Another well-known example of chemistry-related instability includes the oscillatory behavior of the Bheulousov-Zhabotinsky reaction of malonic acid and bromate in the presence of homogeneous Ce catalyst having the overall reaction

Ce can be in two oxidation states, Ce<sup>3+</sup> and Ce<sup>4+</sup>, and there are competing reaction pathways. Complex kinetic models are required to predict the oscillatory behavior, the most well known being that of Noyes [e.g., Showalter, Noyes, and Bar-Eli, *J. Chem. Phys.* **69**(6): 2514–2524 (1978)].

A large body of work has been done to develop criteria that determine the onset of chemistry and transport chemistry-based instabilities. More details and transport-reaction coupling-related examples are discussed in Sec. 19.

## SOFTWARE TOOLS

There are a number of useful software packages that enable efficient analysis of laboratory data for developing the mechanism and kinetics of reactions and for testing the kinetics by using simple reactor models. The reader is referred to search the Internet as some of these software packages change ownership or name. Worth mentioning are the Aspen Engineering Suite (Aspen), the Thermal Safety Software suite (Cheminform St. Petersburg), the Matlab suite (Mathworks), the Chemkin software suite (Reaction Design), the NIST Chemical Kinetics database (NIST), and Gepasi for biochemical kinetics (freeware). The user is advised to experiment and validate any software package with known data and kinetics to ensure robustness and reliability.

## 8-4 PROCESS CONTROL

### Nomenclature

| Symbol      | Definition  | Symbol        | Definition   |
|-------------|---|---------------|--|
| $A$         | Area  | $s$           | Laplace transform variable                               |
| $A_a$       | Actuator area   | $s$           | Search direction   |
| $A_c$       | Output amplitude limits                                 | $S_i$         | Step response coefficient                                |
| $A_v$       | Amplitude of controlled variable                        | $t$           | Time   |
| $A_1$       | Cross-sectional area of tank                            | $T$           | Temperature, target                                      |
| $b$         | Controller output bias                                  | $T(s)$        | Decoupler transfer function                              |
| $B$         | Bottoms flow rate                                       | $T_b$         | Base temperature   |
| $B_i^\circ$ | Limit on control  | $T_f$         | Exhaust temperature                                      |
| $c_A$       | Concentration of A                                      | $T_R$         | Reset time   |
| $C$         | Cumulative sum  | $U$           | Heat-transfer coefficient                                |
| $C_d$       | Discharge coefficient                                   | $u, U$        | Manipulated variable, controller output                  |
| $C_i$       | Inlet concentration                                     | $V$           | Volume   |
| $C_i^\circ$ | Limit on control move                                   | $V_c$         | Product value  |
| $C_L$       | Specific heat of liquid                                 | $w$           | Mass flow rate   |
| $C_0$       | Integration constant                                    | $w_i$         | Weighting factor   |
| $C_p$       | Process capability                                      | $W$           | Steam flow rate  |
| $C_r$       | Heat capacity of reactants                              | $x$           | Mass fraction  |
| $C_v$       | Valve flow coefficient                                  | $\bar{x}$     | Sample mean  |
| $D$         | Distillate flow rate, disturbance                       | $x_i$         | Optimization variable                                    |
| $D_i^\circ$ | Limit on output   | $x_T$         | Pressure drop ratio factor                               |
| $e$         | Error   | $X$           | Transform of deviation variable                          |
| $E$         | Economy of evaporator                                   | $y, Y$        | Process output, controlled variable, valve travel        |
| $f$         | Function of time  | $Y_{sp}$      | Set point  |
| $F, f$      | Feed flow rate  | $z$           | Controller tuning law, expansion factor                  |
| $F_L$       | Pressure recovery factor                                | $z_i$         | Feed mole fraction (distillation)                        |
| $g_c$       | Unit conversion constant                                | $Z$           | Compressibility factor                                   |
| $g_i$       | Algebraic inequality constraint                         |               |  |
| $G$         | Transfer function                                       |               | Greek Symbols  |
| $G_c$       | Controller transfer function                            | $\alpha$      | Digital filter coefficient                               |
| $G_d$       | Disturbance transfer function                           | $a_T$         | Temperature coefficient of resistance                    |
| $G_f$       | Feedforward controller transfer function                | $\beta$       | Resistance thermometer parameter                         |
| $G_m$       | Sensor transfer function                                | $\gamma$      | Ratio of specific heats                                  |
| $G_p$       | Process transfer function                               | $\delta$      | Move suppression factor, shift in target value           |
| $G_t$       | Transmitter transfer function                           | $\Delta q$    | Load step change   |
| $G_v$       | Valve transfer function                                 | $\Delta t$    | Time step  |
| $h_i$       | Algebraic equality constraints                          | $\Delta T$    | Temperature change                                       |
| $h_1$       | Liquid head in tank                                     | $\Delta u$    | Control move   |
| $H$         | Latent heat of vaporization, control limit or threshold | $\varepsilon$ | Spectral emissivity, step size                           |
| $i$         | Summation index   | $\zeta$       | Damping factor (second-order system)                     |
| $I_i$       | Impulse response coefficient                            | $\theta$      | Time delay   |
| $j$         | Time index  | $\lambda$     | Relative gain array parameter, wavelength                |
| $J$         | Objective function or performance index                 | $\Lambda$     | Relative gain array                                      |
| $k$         | Time index  | $\xi$         | Deviation variable                                       |
| $k_f$       | Flow coefficient  | $\rho$        | Density  |
| $k_r$       | Kinetic rate constant                                   | $\sigma$      | Stefan-Boltzmann constant, standard deviation            |
| $K$         | Gain, slack parameter                                   | $\Sigma_t$    | Total response time                                      |
| $K_c$       | Controller gain   | $\tau$        | Time constant  |
| $K_d$       | Disturbance transfer function gain                      | $\tau_d$      | Natural period of closed loop, disturbance time constant |
| $K_m$       | Measurement gain  | $\tau_D$      | Derivative time (PID controller)                         |
| $K_p$       | Process gain  | $\tau_F$      | Filter time constant                                     |
| $K_u$       | Ultimate controller gain (stability)                    | $\tau_I$      | Integral time (PID controller)                           |
| $L$         | Load variable   | $\tau_P$      | Process time constant                                    |
| $L_p$       | Sound pressure level                                    | $\tau_o$      | Period of oscillation                                    |
| $M$         | Manipulated variable                                    | $\phi_{PI}$   | Phase lag  |
| $m_c$       | Number of constraints                                   |               | Subscripts   |
| $M_c$       | Mass flow   | $A$           | Species A  |
| $M_r$       | Mass of reactants                                       | $b$           | Best   |
| $M_w$       | Molecular weight  | $c$           | Controller   |
| $n$         | Number of data points, number of stages or effects      | $d$           | Disturbance  |
| $N$         | Number of inputs/outputs, model horizon                 | $eff$         | Effective  |
| $p$         | Proportional band (%)                                   | $f$           | Feedforward  |
| $p_c$       | Vapor pressure  | $i$           | Initial, inlet   |
| $p_d$       | Actuator pressure                                       | $L$           | Load, disturbance  |
| $p_i$       | Pressure  | $m$           | Measurement or sensor                                    |
| $p_u$       | Proportional band (ultimate)                            | $p$           | Process  |
| $q$         | Radiated energy flux                                    | $s$           | Steady state   |
| $q_b$       | Energy flux to a black body                             | $sp$          | Set-point value  |
| $Q$         | Flow rate   | $t$           | Transmitter  |
| $r_c$       | Number of constraints                                   | $u$           | Ultimate   |
| $R$         | Equal-percentage valve characteristic                   | $v$           | Valve  |
| $R_T$       | Resistance in temperature sensor                        |               |  |
| $R_1$       | Valve resistance  |               |  |

## FUNDAMENTALS OF PROCESS DYNAMICS AND CONTROL

### THE GENERAL CONTROL SYSTEM

A process is shown in Fig. 8-1 with a manipulated input  $U$ , a load input  $D$ , and a controlled output  $Y$ , which could be flow, pressure, liquid level, temperature, composition, or any other inventory, environmental, or quality variable that is to be held at a desired value identified as the set point  $Y_{sp}$ . The load may be a single variable or an aggregate of variables either acting independently or manipulated for other purposes, affecting the controlled variable much as the manipulated variable does. Changes in load may occur randomly as caused by changes in weather, diurnally with ambient temperature, manually when operators change production rate, stepwise when equipment is switched into or out of service, or cyclically as the result of oscillations in other control loops. Variations in load will drive the controlled variable away from the set point, requiring a corresponding change in the manipulated variable to bring it back. The manipulated variable must also change to move the controlled variable from one set point to another.

An open-loop system positions the manipulated variable either manually or on a programmed basis, without using any process measurements. This operation is acceptable for well-defined processes without disturbances. An automated transfer switch is provided to allow manual adjustment of the manipulated variable in case the process or the control system is not performing satisfactorily.

A closed-loop system uses the measurement of one or more process variables to move the manipulated variable to achieve control. Closed-loop systems may include feedforward, feedback, or both.

**Feedback Control** In a feedback control loop, the controlled variable is compared to the set point  $Y_{sp}$ , with the error  $E$  acted upon by the controller to move  $U$  in such a way as to minimize the error. This action is specifically negative feedback, in that an increase in error moves  $U$  so as to decrease the error. (Positive feedback would cause the error to expand rather than diminish and therefore does not regulate.) The action of the controller is selectable to allow use on process gains of both signs.

The controller has tuning parameters related to proportional, integral, derivative, lag, dead time, and sampling functions. A negative feedback loop will oscillate if the controller gain is too high; but if it is too low, control will be ineffective. The controller parameters must be properly related to the process parameters to ensure closed-loop stability while still providing effective control. This relationship is accomplished, first,

by the proper selection of control modes to satisfy the requirements of the process and, second, by the appropriate tuning of those modes.

**Feedforward Control** A feedforward system uses measurements of disturbance variables to position the manipulated variable in such a way as to minimize any resulting deviation. The disturbance variables could be either measured loads or the set point, the former being more common. The feedforward gain must be set precisely to reduce the deviation of the controlled variable from the set point.

Feedforward control is usually combined with feedback control to eliminate any offset resulting from inaccurate measurements and calculations and unmeasured load components. The feedback controller can be used as a bias on the feedforward controller or in a multiplicative form.

**Computer Control** Computers have been used to replace analog PID controllers, either by setting set points of lower-level controllers in supervisory control or by driving valves directly in direct digital control. Single-station digital controllers perform PID control in one or two loops, including computing functions such as mathematical operations, characterization, lags, and dead time, with digital logic and alarms. Distributed control systems provide all these functions, with the digital processor shared among many control loops; separate processors may be used for displays, communications, file servers, and the like. A host computer may be added to perform high-level operations such as scheduling, optimization, and multivariable control. More details on computer control are provided later in this section.

### PROCESS DYNAMICS AND MATHEMATICAL MODELS

**GENERAL REFERENCES:** Seborg, Edgar, and Mellichamp, *Process Dynamics and Control*, Wiley, New York, 2004; Marlin, *Process Control*, McGraw-Hill, New York, 2000; Ogunnaike and Ray, *Process Dynamics Modeling and Control*, Oxford University Press, New York, 1994; Smith and Corripio, *Principles and Practices of Automatic Process Control*, Wiley, New York, 1997.

**Open-Loop versus Closed-Loop Dynamics** It is common in industry to manipulate coolant in a jacketed reactor in order to control conditions in the reactor itself. A simplified schematic diagram of such a reactor control system is shown in Fig. 8-2. Assume that the reactor temperature is adjusted by a controller that increases the coolant flow in proportion to the difference between the desired reactor temperature and the temperature that is measured. The proportionality constant is  $K_c$ . If a small change in the temperature of the inlet stream occurs, then

FIG. 8-1 Block diagram for feedforward and feedback control.

## 8-6 PROCESS CONTROL

FIG. 8-2 Reactor control system.

depending on the value of  $K_c$ , one might observe the reactor temperature responses shown in Fig. 8-3. The top plot shows the case for no control ( $K_c = 0$ ), which is called the open loop, or the normal dynamic response of the process by itself. As  $K_c$  increases, several effects can be noted. First, the reactor temperature responds faster and faster. Second, for the initial increases in  $K$ , the maximum deviation in the reactor temperature becomes smaller. Both of these effects are desirable so that disturbances from normal operation have as small an effect as possible on the process under study. As the gain is increased further, eventually a point is reached where the reactor temperature oscillates indefinitely, which is undesirable. This point is called the stability limit, where  $K_c = K_u$ , the ultimate controller gain. Increasing  $K_c$  further causes the magnitude of the oscillations to increase, with the result that the control valve will cycle between full open and closed.

The responses shown in Fig. 8-3 are typical of the vast majority of regulatory loops encountered in the process industries. Figure 8-3

shows that there is an optimal choice for  $K_c$ , somewhere between 0 (no control) and  $K_u$  (stability limit). If one has a dynamic model of a process, then this model can be used to calculate controller settings. In Fig. 8-3, no time scale is given, but rather the figure shows relative responses. A well-designed controller might be able to speed up the response of a process by a factor of roughly 2 to 4. Exactly how fast the control system responds is determined by the dynamics of the process itself.

**Physical Models versus Empirical Models** In developing a dynamic process model, there are two distinct approaches that can be taken. The first involves models based on first principles, called physical or first principles models, and the second involves empirical models. The conservation laws of mass, energy, and momentum form the basis for developing physical models. The resulting models typically involve sets of differential and algebraic equations that must be solved simultaneously. Empirical models, by contrast, involve postulating the form of a dynamic model, usually as a transfer function, which is discussed below. This transfer function contains a number of parameters that need to be estimated from data. For the development of both physical and empirical models, the most expensive step normally involves verification of their accuracy in predicting plant behavior.

To illustrate the development of a physical model, a simplified treatment of the reactor, shown in Fig. 8-2, is used. It is assumed that the reactor is operating isothermally and that the inlet and exit volumetric flows and densities are the same. There are two components, A and B, in the reactor, and a single first-order reaction of  $A \rightarrow B$  takes place. The inlet concentration of A, which we call  $c_{iA}$ , varies with time. A dynamic mass balance for the concentration of A, denoted  $c_A$ , can be written as follows:

$$V \frac{dc_A}{dt} = Fc_i - Fc_A - k_r V c_A \quad (8-1)$$

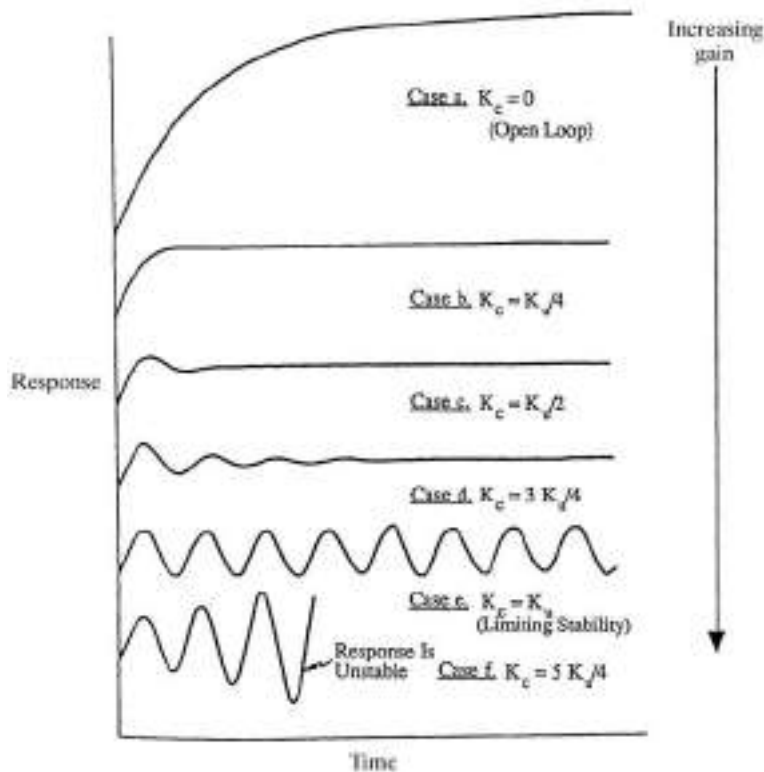

FIG. 8-3 Typical control system responses.

In Eq. (8-1), the flow in of component A is  $Fc_i$ , the flow out is  $Fc_A$ , and the loss via reaction is  $k_r V c_A$ , where  $V$  = reactor volume and  $k_r$  = kinetic rate constant. In this example,  $c_i$  is the input, or forcing, variable and  $c_A$  is the output variable. If  $V$ ,  $F$ , and  $k_r$  are constant, Eq. (8-1) can be rearranged by dividing by  $F + k_r V$  so that it contains only two groups of parameters. The result is

$$\tau \frac{dc_A}{dt} = Kc_i - c_A \tag{8-2}$$

where  $\tau = V/(F + k_r V)$  and  $K = F/(F + k_r V)$ . For this example, the resulting model is a first-order differential equation in which  $\tau$  is called the time constant and  $K$  the process gain.

As an alternative to deriving Eq. (8-2) from a dynamic mass balance, one could simply postulate a first-order differential equation to be valid (empirical modeling). Then it would be necessary to estimate values for  $\tau$  and  $K$  so that the postulated model described the reactor's dynamic response. The advantage of the physical model over the empirical model is that the physical model gives insight into how reactor parameters affect the values of  $\tau$  and  $K$ , which in turn affects the dynamic response of the reactor.

**Nonlinear versus Linear Models** If  $V$ ,  $F$ , and  $k$  are constant, then Eq. (8-1) is an example of a linear differential equation model. In a linear equation, the output and input variables and their derivatives appear to only the first power. If the rate of reaction were second-order, then the resulting dynamic mass balance would be

$$V \frac{dc_A}{dt} = Fc_i - Fc_A - k_r V c_A^2 \tag{8-3}$$

Since  $c_A$  appears in this equation to the second power, the equation is nonlinear.

The difference between linear systems and nonlinear systems can be seen by considering the steady-state behavior of Eq. (8-1) compared to Eq. (8-3) (the left-hand side is zero; that is,  $dc_A/dt = 0$ ). For a given change in  $c_i$ ,  $\Delta c_i$ , the change in  $c_A$  calculated from Eq. (8-1),  $\Delta c_A$ , is always proportional to  $\Delta c_i$ , and the proportionality constant is  $K$  [see Eq. (8-2)]. The change in the output of a system divided by a change in the input to the system is called the *process gain*. Linear systems have constant process gains for all changes in the input. By contrast, Eq. (8-3) gives a  $\Delta c_A$  that varies with  $\Delta c_i$ , which is a function of the concentration levels in the reactor. Thus, depending on the reactor operating conditions, a change in  $c_i$  produces different changes in  $c_A$ . In this case, the process has a nonlinear gain. Systems with nonlinear gains are more difficult to control than linear systems that have constant gains.

**Simulation of Dynamic Models** Linear dynamic models are particularly useful for analyzing control system behavior. The insight gained through linear analysis is invaluable. However, accurate dynamic process models can involve large sets of nonlinear equations. Analytical solution of these models is not possible. Thus, in these cases, one must turn to simulation approaches to study process dynamics and the effect of process control. Equation (8-3) will be used to illustrate the simulation of nonlinear processes. If  $dc_A/dt$  on the left-hand side of Eq. (8-3) is replaced with its finite difference approximation, one gets

$$c_A(t + \Delta t) = \frac{c_A(t) + \Delta t \cdot [Fc_i(t) - Fc_A(t) - k_r V c_A^2(t)]}{V} \tag{8-4}$$

Starting with an initial value of  $c_A$  and given  $c_i(t)$ , Eq. (8-4) can be solved for  $c_A(t + \Delta t)$ . Once  $c_A(t + \Delta t)$  is known, the solution process can be repeated to calculate  $c_A(t + 2\Delta t)$ , and so on. This approach is called the Euler integration method; while it is simple, it is not necessarily the best approach to numerically integrating nonlinear differential equations. As discussed in Sec. 3, more sophisticated approaches are available that allow much larger step sizes to be taken but require additional calculations. One widely used approach is the fourth-order Runge Kutta method, which involves the following calculations:

Define

$$f(c_A t) = \frac{Fc_i(t) - Fc_A - k_r V c_A^2}{V} \tag{8-5}$$

then

$$c_A(t + \Delta t) = c_A(t) + \Delta t(m_1 + 2m_2 + 2m_3 + m_4) \tag{8-6}$$

with

$$m_1 = f[c_A(t), t] \tag{8-7}$$

$$m_2 = f\left[c_A(t) + 2\frac{m_1 \Delta t}{2}, t + \frac{\Delta t}{2}\right] \tag{8-8}$$

$$m_3 = f\left[c_A(t) + 2\frac{m_2 \Delta t}{2}, t + \frac{\Delta t}{2}\right] \tag{8-9}$$

$$m_4 = f[c_A(t) + m_3 \Delta t, t + \Delta t] \tag{8-10}$$

In this method, the  $m_i$ 's are calculated sequentially in order to take a step in time. Even though this method requires calculation of the four additional  $m_i$  values, for equivalent accuracy the fourth-order Runge Kutta method can result in a faster numerical solution, because it permits a larger step  $\Delta t$  to be taken. Increasingly sophisticated simulation packages are being used to calculate the dynamic behavior of processes and to test control system behavior. These packages have good user interfaces, and they can handle stiff systems where some variables respond on a time scale that is much much faster or slower than that of other variables. A simple Euler approach cannot effectively handle stiff systems, which frequently occur in chemical process models. See Sec. 3 of this handbook for more details.

**Laplace Transforms** When mathematical models are used to describe process dynamics in conjunction with control system analysis, the models generally involve linear differential equations. Laplace transforms are very effective for solving linear differential equations. The key advantage of using Laplace transforms is that they convert differential equations to algebraic equations. The resulting algebraic equations are easier to solve than the original differential equations. When the Laplace transform is applied to a linear differential equation in time, the result is an algebraic equation in a new variable  $s$ , called the Laplace variable. To get the solution to the original differential equation, one needs to invert the Laplace transform. Table 8-1 gives a number of useful Laplace transform pairs, and more extensive tables are available (Seborg, Edgar, and Mellichamp, *Process Dynamics and Control*, Wiley, New York, 2004).

To illustrate how Laplace transforms work, consider the problem of solving Eq. (8-2), subject to the initial condition that  $c_A = c_i = 0$  at  $t = 0$ . If  $c_A$  were not initially zero, one would define a deviation variable between  $c_A$  and its initial value  $c_{A0}$ . Then the transfer function would be developed by using this deviation variable. If  $c_i$  changes from zero to  $\bar{c}_i$ , taking the Laplace transform of both sides of Eq. (8-2) gives

$$\mathcal{L}\left(\tau \frac{dc_A}{dt}\right) = \mathcal{L}(K\bar{c}_i) - \mathcal{L}(c_A) \tag{8-11}$$

**TABLE 8-1 Frequently Used Laplace Transforms**

| Time function $f(t)$ | Transform $F(s)$           |
|----------------------|----------------------------|
| $A$                  | $A/s$                      |
| $At$                 | $A/s^2$                    |
| $Ae^{-at}$           | $A/(s + a)$                |
| $A(1 - e^{-t\tau})$  | $A/[s(\tau s + 1)]$        |
| $A \sin \omega t$    | $A\omega/(s^2 + \omega^2)$ |
| $f(t - \theta)$      | $e^{-s\theta}F(s)$         |
| $df/dt$              | $sF(s) - f(0)$             |
| $\int f(t)dt$        | $F(s)/s$                   |

## 8-8 PROCESS CONTROL

Denoting  $\mathcal{L}(C_A)$  as  $C_A(s)$  and using the relationships in Table 8-1 give

$$\tau s C_A(s) = \frac{K\bar{C}_i}{s} - C_A(s) \quad (8-12)$$

Equation (8-12) can be solved for  $C_A$  to give

$$C_A(s) = \frac{K\bar{C}_i/s}{\tau s + 1} \quad (8-13)$$

By using the entries in Table 8-1, Eq. (8-13) can be inverted to give the transient response of  $c_A$  as

$$c_A(t) = (K\bar{c}_i)(1 - e^{-t/\tau}) \quad (8-14)$$

Equation (8-14) shows that  $c_A$  starts from 0 and builds up exponentially to a final concentration of  $K\bar{c}_i$ . Note that to get Eq. (8-14), it was only necessary to solve the algebraic Eq. (8-12) and then find the inverse of  $C_A(s)$  in Table 8-1. The original differential equation was not solved directly. In general, techniques such as partial fraction expansion must be used to solve higher-order differential equations with Laplace transforms.

**Transfer Functions and Block Diagrams** A very convenient and compact method of representing the process dynamics of linear systems involves the use of transfer functions and block diagrams. A transfer function can be obtained by starting with a physical model, as discussed previously. If the physical model is nonlinear, first it needs to be linearized around an operating point. The resulting linearized model is then approximately valid in a region around this operating point. To illustrate how transfer functions are developed, Eq. (8-2) will again be used. First, one defines deviation variables, which are the process variables minus their steady-state values at the operating point. For Eq. (8-2), there would be deviation variables for both  $c_A$  and  $c_b$ , and these are defined as

$$\xi = c_A - \bar{c}_A \quad (8-15)$$

$$\xi_i = c_i - \bar{c}_i \quad (8-16)$$

where the overbar stands for steady state. Substitution of Eqs. (8-15) and (8-16) into Eq. (8-2) gives

$$\tau \frac{d\xi}{dt} = K\xi_i - \xi + (K\bar{c}_i - \bar{c}_A) \quad (8-17)$$

The term in parentheses in Eq. (8-17) is zero at steady state, and thus it can be dropped. Next the Laplace transform is taken, and the resulting algebraic equation is solved.

By denoting  $X(s)$  as the Laplace transform of  $\xi$  and  $X_i(s)$  as the transform of  $\xi_i$ , the final transfer function can be written as

$$\frac{X}{X_i} = \frac{K}{\tau s + 1} \quad (8-18)$$

Equation (8-18) is an example of a first-order transfer function. As mentioned above, an alternative to formally deriving Eq. (8-18) involves simply postulating its form and then identifying its two parameters, the process gain  $K$  and time constant  $\tau$ , to fit the process under study. In fitting the parameters, data can be generated by forcing the process. If step forcing is used, then the resulting response is called the process reaction curve. Often transfer functions are placed in block diagrams, as shown in Fig. 8-4. Block diagrams show how changes in an input variable affect an output variable. Block diagrams are a means of concisely representing the dynamics of a process under study. Since linearity is assumed in developing a block diagram, if more than one variable affects an output, the contributions from each can be added.

**Continuous versus Discrete Models** The preceding discussion has focused on systems where variables change continuously with

FIG. 8-4 First-order transfer function.

time. Most real processes have variables that are continuous, such as temperature, pressure, and flow. However, some processes involve discrete events, such as the starting or stopping of a pump. In addition, modern plants are controlled by digital computers, which are discrete. In controlling a process, a digital system samples variables at a fixed rate, and the resulting system is a sampled data system. From one sampling instant until the next, variables are assumed to remain fixed at their sampled values. Similarly, in controlling a process, a digital computer sends out signals to control elements, usually valves, at discrete instants of time. These signals remain fixed until the next sampling instant.

Figure 8-5 illustrates the concept of sampling a continuous function. At integer values of the sampling rate  $\Delta t$ , the value of the variable to be sampled is measured and held until the next sampling instant. To deal with sampled data systems, the  $z$  transform has been developed. The  $z$  transform of the function given in Fig. 8-5 is defined as

$$Z(f) = \sum_{n=0}^{\infty} f(n \Delta t) z^{-n} \quad (8-19)$$

In an analogous manner to Laplace transforms, one can develop transfer functions in the  $z$  domain as well as block diagrams. Tables of  $z$  transform pairs have been published (Seborg, Edgar, and Mellichamp, *Process Dynamics and Control*, Wiley, New York, 2004) so that the discrete transfer functions can be inverted back to the time domain. The inverse gives the value of the function at the discrete sampling instants. Sampling a continuous variable results in a loss of information. However, in practical applications, sampling is fast enough that the loss is typically insignificant and the difference between continuous and discrete modeling is small in terms of its effect on control. Increasingly, model predictive controllers that make use of discrete dynamic models are being used in the process industries. The purpose of these controllers is to guide a process to optimum operating points. These model predictive control algorithms are typically run at much slower sampling rates than are used for basic control loops such as flow control or pressure control. The discrete dynamic models used are normally developed from data generated

FIG. 8-5 Sampled data example.

FIG. 8-6 Single tank with exit valve.

from plant testing, as discussed hereafter. For a detailed discussion of modeling sampled data systems, the interested reader is referred to textbooks on digital control (Astrom and Wittenmark, *Computer Controlled Systems*, Prentice-Hall, Englewood Cliffs, N.J., 1997).

**Process Characteristics in Transfer Functions** In many cases, process characteristics are expressed in the form of transfer functions. In the previous discussion, a reactor example was used to illustrate how a transfer function could be derived. Here, another system involving flow out of a tank, shown in Fig. 8-6, is considered.

**Proportional Element** First, consider the outflow through the exit valve on the tank. If the flow through the line is turbulent, then Bernoulli's equation can be used to relate the flow rate through the valve to the pressure drop across the valve as

$$f_1 = k_f A_v \sqrt{2g_c(h_1 - h_0)} \tag{8-20}$$

where  $f_1$  = flow rate,  $k_f$  = flow coefficient,  $A_v$  = cross-sectional area of the restriction,  $g_c$  = constant,  $h_1$  = liquid head in tank (pressure at the base of the tank), and  $h_0$  = atmospheric pressure. This relationship between flow and pressure drop across the valve is nonlinear, and it can be linearized around a particular operating point to give

$$f_1 - \bar{f}_1 = \left(\frac{1}{R_1}\right)(h_1 - \bar{h}_1) \tag{8-21}$$

where  $R_1 = \bar{f}_1 / (g_c k_f^2 A_v^2)$  is called the resistance of the valve in analogy with an electrical resistance. The transfer function relating changes in flow to changes in head is shown in Fig. 8-7, and it is an example of a pure gain system with no dynamics. In this case, the process gain is  $K = 1/R_1$ . Such a system has an instantaneous dynamic response, and for a step change in head, there is an immediate step change in flow, as shown in Fig. 8-8. The exact magnitude of the step in flow depends on the operating flow  $\bar{f}_1$  as the definition of  $R_1$  shows.

**First-Order Lag (Time Constant Element)** Next consider the system to be the tank itself. A dynamic mass balance on the tank gives

$$A_1 \frac{dh_1}{dt} = f_i - f_1 \tag{8-22}$$

where  $A_1$  is the cross-sectional area of the tank and  $f_i$  is the inlet flow. By substituting Eq. (8-21) into Eq. (8-22) and following the approach

FIG. 8-7 Proportional element transfer function.

FIG. 8-8 Response of proportional element.

discussed above for deriving transfer functions, one can develop the transfer function relating changes in  $h_1$  to changes in  $f_1$ . The resulting transfer function is another example of a first-order system, shown in Fig. 8-4, and it has a gain  $K = R_1$  and a time constant  $\tau_1 = R_1 A_1$ . For a step change in  $f_i$ ,  $h_1$  follows a decaying exponential response from its initial value  $\bar{h}_1$  to a final value of  $\bar{h}_1 + R_1 \Delta f_i$  (Fig. 8-9). At a time equal to  $\tau_1$ , the transient in  $h_1$  is 63 percent finished; and at  $3\tau_1$ , the response is 95 percent finished. These percentages are the same for all first-order processes. Thus, knowledge of the time constant of a first-order process gives insight into how fast the process responds to sudden input changes.

**Capacity Element** Now consider the case where the valve in Fig. 8-7 is replaced with a pump. In this case, it is reasonable to assume that the exit flow from the tank is independent of the level in the tank. For such a case, Eq. (8-22) still holds, except that  $f_1$  no longer depends on  $h_1$ . For changes in  $f_i$ , the transfer function relating changes in  $h_1$  to changes in  $f_i$  is shown in Fig. 8-10. This is an example of a pure capacity process, also called an integrating system. The cross-sectional area of the tank is the chemical process equivalent of an electrical capacitor. If the inlet flow is step forced while the outlet is held constant, then the level builds up linearly, as shown in Fig. 8-11. Eventually the liquid will overflow the tank.

**Second-Order Element** Because of their linear nature, transfer functions can be combined in a straightforward manner. Consider the two-tank system shown in Fig. 8-12. For tank 1, the transfer function relating changes in  $f_1$  to changes in  $f_i$  is

$$\frac{F_1(s)}{F_i(s)} = \frac{1}{A_1 R_1 + 1} \tag{8-23}$$

Since  $f_1$  is the inlet flow to tank 2, the transfer function relating changes in  $h_2$  to changes in  $f_1$  has the same form as that given in Fig. 8-4:

$$\frac{H_2(s)}{F_1(s)} = \frac{R_2}{A_2 R_2 s + 1} \tag{8-24}$$

Equations (8-23) and (8-24) can be multiplied to give the final transfer function relating changes in  $h_2$  to changes in  $f_i$ , as shown in Fig. 8-13. This is an example of a second-order transfer function. This transfer function has a gain  $R_2$  and two time constants  $A_1 R_1$  and  $A_2 R_2$ . For two tanks with equal areas, a step change in  $f_i$  produces the S-shaped response in level in the second tank shown in Fig. 8-14.

**General Second-Order Element** Figure 8-3 illustrates the fact that closed-loop systems can exhibit oscillatory behavior. A general second-order transfer function that can exhibit oscillatory behavior is important for the study of automatic control systems. Such a transfer function is given in Fig. 8-15. For a unit step input, the transient responses shown in Fig. 8-16 result. As can be seen, when  $\zeta < 1$ , the response oscillates; and when  $\zeta < 1$ , the response is S-shaped. Few open-loop chemical processes exhibit an oscillating response; most exhibit an S-shaped step response.

FIG. 8-9 Response of first-order system.

**Distance-Velocity Lag (Dead-Time Element)** The dead-time or time-delay element, commonly called a distance-velocity lag, is often encountered in process systems. For example, if a temperature-measuring element is located downstream from a heat exchanger, a time delay occurs before the heated fluid leaving the exchanger

arrives at the temperature measurement point. If some element of a system produces a dead time of  $\theta$  time units, then an input to that unit  $f(t)$  will be reproduced at the output as  $f(t - \theta)$ . The transfer function for a pure dead-time element is shown in Fig. 8-17, and the transient response of the element is shown in Fig. 8-18.

FIG. 8-15 General second-order transfer function.

FIG. 8-16 Response of general second-order system.

FIG. 8-17 Dead-time transfer function.

FIG. 8-18 Response of dead-time system.

**Higher-Order Lags** If a process is described by a series of  $n$  first-order lags, the overall system response becomes proportionally slower with each lag added. The special case of a series of  $n$  first-order lags with equal time constants has a transfer function given by

$$G(s) = \frac{K}{(\tau s + 1)^n} \quad (8-25)$$

The step response of this transfer function is shown in Fig. 8-19. Note that all curves reach about 60 percent of their final value at  $t = n\tau$ .

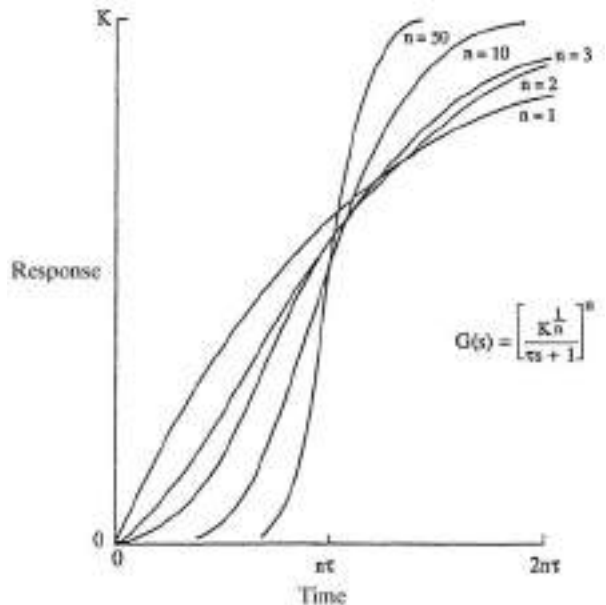

FIG. 8-19 Response of  $n$ th-order lags.

FIG. 8-20 Example of  $2 \times 2$  transfer function.

Higher-order systems can be approximated by a first- or second-order plus dead-time system for control system design.

**Multi-input, Multioutput Systems** The dynamic systems considered up to this point have been examples of single-input, single-output (SISO) systems. In chemical processes, one often encounters systems where one input can affect more than one output. For example, assume that one is studying a distillation tower in which both reflux and boil-up are manipulated for control purposes. If the output variables are the top and bottom product compositions, then each input affects both outputs. For this distillation example, the process is referred to as a  $2 \times 2$  system to indicate the number of inputs and outputs. In general, multi-input, multioutput (MIMO) systems can have  $n$  inputs and  $m$  outputs with  $n \neq m$ , and they can be nonlinear. Such a system would be called an  $n \times m$  system. An example of a transfer function for a  $2 \times 2$  linear system is given in Fig. 8-20. Note that since linear systems are involved, the effects of the two inputs on each output are additive. In many process control systems, one input is selected to control one output in a MIMO system. For  $m$  outputs there would be  $m$  such selections. For this type of control strategy, one needs to consider which inputs and outputs to couple, and this problem is referred to as loop pairing. Another important issue that arises involves interaction between control loops. When one loop makes a change in its manipulated variable, the change affects the other loops in the system. These changes are the direct result of the multivariable nature of the process. In some cases, the interaction can be so severe that overall control system performance is drastically reduced. Finally, some of the modern approaches to process control tackle the MIMO problem directly, and they simultaneously use all manipulated variables to control all output variables rather than pair one input to one output (see later section on multivariable control).

**Fitting Dynamic Models to Experimental Data** In developing empirical transfer functions, it is necessary to identify model parameters from experimental data. There are a number of approaches to process identification that have been published. The simplest approach involves introducing a step test into the process and recording the response of the process, as illustrated in Fig. 8-21. The  $x$ 's in the figure represent the recorded data. For purposes of illustration, the process under study will be assumed to be first-order with dead time and have the transfer function

$$G(s) = \frac{Y(s)}{U(s)} = K \exp(-\theta s) / \tau s + 1 \quad (8-26)$$

The response  $y(t)$ , produced by Eq. (8-26) can be found by inverting the transfer function, and it is also shown in Fig. 8-21 for a set of

model parameters  $K$ ,  $\tau$ , and  $\theta$  fitted to the data. These parameters are calculated by using optimization to minimize the squared difference between the model predictions and the data, i.e., a least squares approach. Let each measured data point be represented by  $y_j$  (measured response),  $t_j$  (time of measured response),  $j = 1$  to  $n$ . Then the least squares problem can be formulated as

$$\min_{\tau, \theta, K} \sum_{j=1}^n [y_j - \hat{y}(t_j)]^2 \quad (8-27)$$

where  $\hat{y}(t_j)$  is the predicted value of  $y$  at time  $t_j$  and  $n$  is the number of data points. This optimization problem can be solved to calculate the optimal values of  $K$ ,  $\tau$ , and  $\theta$ . A number of software packages such as Excel Solver are available for minimizing Eq. (8-27).

One operational problem caused by step forcing is the fact that the process under study is moved away from its steady-state operating point. Plant managers may be reluctant to allow large steady-state changes, since normal production will be disturbed by the changes. As a result, alternative methods of forcing actual processes have been developed, and these included pulse testing and pseudo-random binary signal (PRBS) forcing, both of which are illustrated in Fig. 8-22. With pulse forcing, one introduces a step, and then after a period of time the input is returned to its original value. The result is that the process dynamics are excited, but after the forcing the process returns to its original steady state. PRBS forcing involves a series of pulses of fixed height and random duration, as shown in Fig. 8-22. The advantage of PRBS is that forcing can be concentrated on particular frequency ranges that are important for control system design.

Transfer function models are linear, but chemical processes are known to exhibit nonlinear behavior. One could use the same type of optimization objective as given in Eq. (8-27) to determine parameters in nonlinear first-principles models, such as Eq. (8-3) presented earlier. Also, nonlinear empirical models, such as neural network models, have recently been proposed for process applications. The key to the use of these nonlinear empirical models is to have high-quality process data, which allows the important nonlinearities to be identified.

## FEEDBACK CONTROL SYSTEM CHARACTERISTICS

**GENERAL REFERENCES:** Shinskey, *Process Control Systems*, 4th ed., McGraw-Hill, New York, 1996; Seborg, Edgar, and Mellichamp, *Process Dynamics and Control*, Wiley, New York, 1989.

FIG. 8-21 Plot of experimental data and first-order model fit.

There are two objectives in applying feedback control: (1) regulate the controlled variable at the set point following changes in load and (2) respond to set-point changes, the latter called servo operation. In fluid processes, almost all control loops must contend with variations in load, and therefore regulation is of primary importance. While most loops will operate continuously at fixed set points, frequent changes in set points can occur in flow loops and in batch production. The most common mechanism for achieving both objectives is feedback control, because it is the simplest and most universally applicable approach to the problem.

**Closing the Loop** The simplest representation of the closed feedback loop is shown in Fig. 8-23. The load is shown entering the process at the same point as the manipulated variable because that is the most common point of entry, and because, lacking better information, the elements in the path of the manipulated variable are the best estimates of those in the load path. The load rarely impacts directly on the controlled variable without passing through the dominant lag in the process. Where the load is unmeasured, its current value can be observed as the controller output required to keep the controlled variable  $Y$  at set point  $Y_{sp}$ .

If the loop is opened—either by placing the controller in manual operation or by setting its gains to zero—the load will have complete influence over the controlled variable, and the set point will have none. Only by closing the loop with controller gain as high as possible will the influence of the load be minimized and that of the set point be maximized. There is a practical limit to the controller gain, however, at the point where the controlled variable develops a uniform oscillation. This is defined as the limit of stability, and it is reached when the product of gains in the loop  $\Pi G = G_c G_p G_r$  is equal to 1.0 at the period of the oscillation. If the gain of any element in the loop increases from this condition, oscillations will expand, creating a dangerous situation where safe limits of operation could be exceeded in a few cycles. Consequently, control loops should be left in a condition where the loop gain is less than 1.0 by a safe margin that allows for possible variations in process parameters. Figure 8-24 describes a load response under PID (proportional-integral-derivative) control where the loop is well damped at a loop gain of 0.56; loop gain is then increased to 0.93 and to 1.05, creating a lightly damped and then an expanding cycle, respectively.

In controller tuning, a choice must be made between performance and robustness. Performance is a measure of how well a given con-

troller with certain parameter settings regulates a variable, relative to the best response that can be achieved for that particular process. Robustness is a measure of how small a change in a process parameter is required to bring the loop from its current state to the limit of stability ( $\Pi G = 1.0$ ). The well-damped loop in Fig. 8-24 has a robustness of 79 percent, in that increasing the gain of any element in the loop by a factor of 1/0.56, or 1.79, would bring the loop to the limit of stability. Increasing controller performance by raising its gain can therefore be expected to decrease robustness. Both performance and robustness are functions of the dynamics of the process being controlled, the selection of the controller, and the tuning of the controller parameters.

**On/Off Control** An on/off controller is used for manipulated variables having only two states. They commonly control temperatures in homes, electric water heaters and refrigerators, and pressure and liquid level in pumped storage systems. On/off control is satisfactory where slow cycling is acceptable, because it always leads to cycling when the load lies between the two states of the manipulated variable. The cycle will be positioned symmetrically about the set point only if the load happens to be equidistant between the two states of the manipulated variable. The period of the symmetric cycle will be approximately  $4\theta$ , where  $\theta$  is the dead time in the loop. If the load is not centered between the states of the manipulated variable, the period will tend to increase and the cycle will follow a sawtooth pattern.

Every on/off controller has some degree of dead band, also known as lockup, or differential gap. Its function is to prevent erratic switching between states, thereby extending the life of contacts and motors. Instead of changing states precisely when the controlled variable crosses the set point, the controller will change states at two different points for increasing and decreasing signals. The difference between these two switching points is the dead band (see Fig. 8-25); it increases the amplitude and period of the cycle, similar to the effects of dead time.

A three-state controller is used to drive either a pair of independent two-state actuators, such as heating and cooling valves, or a bidirectional motorized actuator. The controller is comprised of two on/off controllers, each with dead band, separated by a dead zone. While the controlled variable lies within the dead zone, neither output is energized. This controller can drive a motorized valve to the point where the manipulated variable matches the load, thereby avoiding cycling.

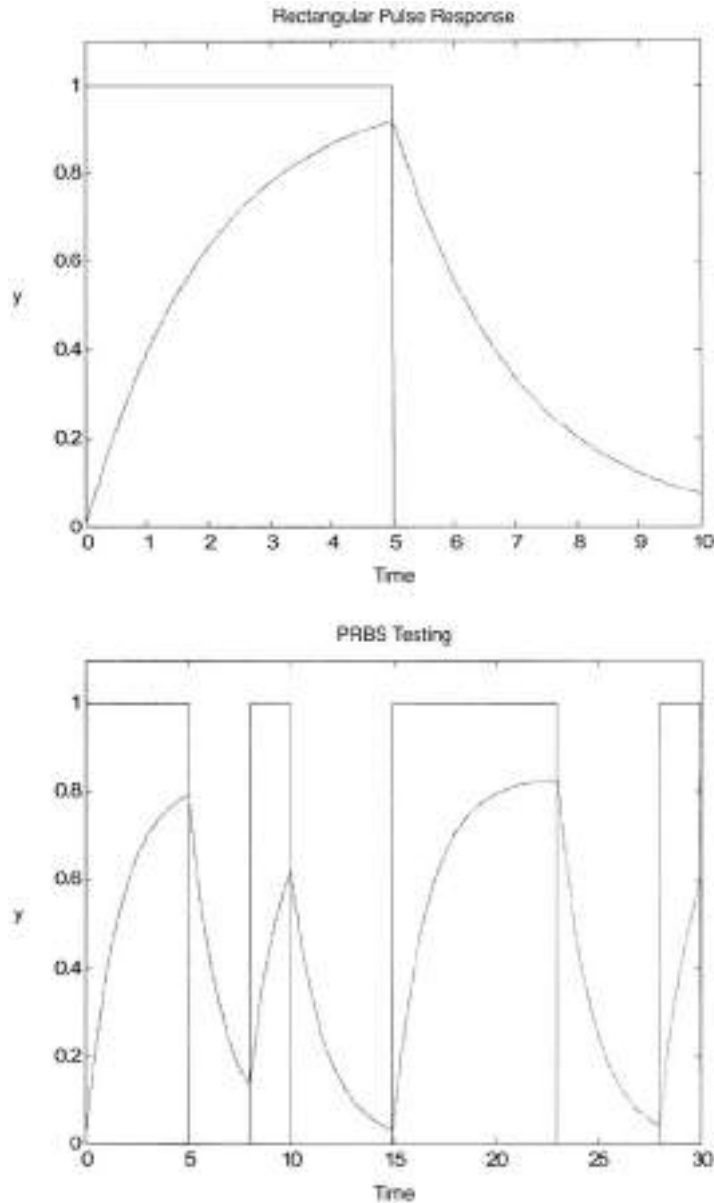

FIG. 8-22 Rectangular pulse response and PRBS testing.

**Proportional Control** A proportional controller moves its output proportional to the deviation  $e$  between the controlled variable  $y$  and its set point  $y_{sp}$ :

$$u = K_c e + b = \frac{100}{P} e + b \quad (8-28)$$

where  $e = \pm(y - y_{sp})$ , the sign selected to produce negative feedback. In some controllers, proportional gain  $K_c$  is introduced as a pure number; in others, it is set as  $100/P$ , where  $P$  is the proportional band in percent. The output bias  $b$  of the controller is also known as manual reset. The proportional controller is not a good regulator, because any change in output required to respond to a change in load results in a corresponding change in the controlled variable. To minimize the resulting offset, the bias

should be set at the best estimate of the load, and the proportional band set as low as possible. Processes requiring a proportional band of more than a few percent may control with unacceptably large values of offset.

Proportional control is most often used to regulate liquid level, where variations in the controlled variable carry no economic penalty and where other control modes can easily destabilize the loop. It is actually recommended for controlling the level in a surge tank when manipulating the flow of feed to a critical downstream process. By setting the proportional band just under 100 percent, the level is allowed to vary over the full range of the tank capacity as inflow fluctuates, thereby minimizing the resulting rate of change of manipulated outflow. This technique is called averaging level control.

**Proportional-plus-Integral (PI) Control** Integral action eliminates the offset described above by moving the controller output at a

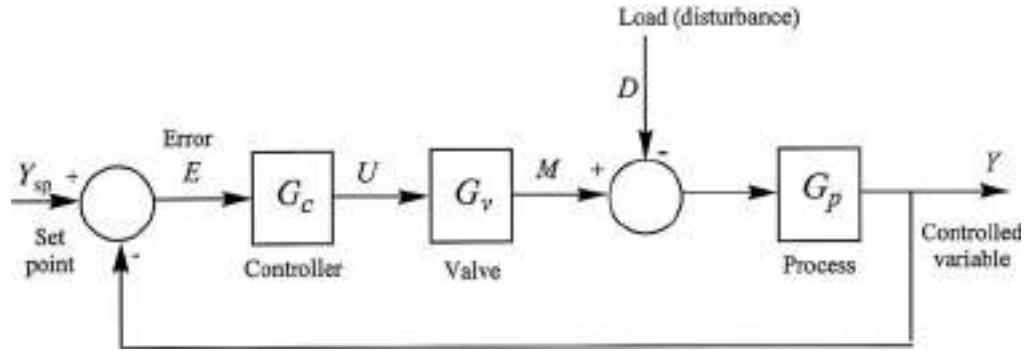

FIG. 8-23 Both load regulation and set-point response require high gains for the feedback controller.

rate proportional to the deviation from set point—the output will then not stop moving until the deviation is zero. Although available alone in an integral controller, it is most often combined with proportional action in a PI controller:

$$u = \frac{100}{P} \left( e + \frac{1}{\tau_i} \int e dt \right) + C_0 \quad (8-29)$$

where  $\tau_i$  is the integral time constant in minutes; in some controllers it is introduced as integral gain or reset rate  $1/\tau_i$  in repeats per minute. The last term in the equation is the constant of integration, the value of the controller output when integration begins. The PI controller is by far the most commonly used controller in the process industries.

Because the integral term lags the proportional term by  $90^\circ$  in phase, the PI controller then always produces a phase lag between  $0^\circ$  and  $90^\circ$ :

$$\phi_{PI} = -\tan^{-1} \frac{\tau_o}{2\pi\tau_i} \quad (8-30)$$

where  $\tau_o$  is the period of oscillation of the loop. The phase angle should be kept between  $15^\circ$  for lag-dominant processes and  $45^\circ$  for dead-time-dominant processes for optimum results.

**Proportional-plus-Integral-plus-Derivative (PID) Control** The derivative mode moves the controller output as a function of the rate of change of the controlled variable, which adds phase lead to the controller, increasing its speed of response. It is normally combined with proportional and integral modes. The noninteracting or ideal form of the PID controller appears functionally as

$$u = \frac{100}{P} \left( e + \frac{1}{\tau_i} \int e dt \pm \tau_D \frac{dy}{dt} \right) + C_0 \quad (8-31)$$

where  $\tau_D$  is the derivative time constant. Note that derivative action is applied to the controlled variable rather than to the deviation, as it should not be applied to the set point; the selection of the sign for the derivative term must be consistent with the action of the controller.

In some PID controllers, the integral and derivative terms are combined serially rather than in parallel, as done in the last equation. This results in interaction between these modes, such that the effective values of the controller parameters differ from their set values as follows:

$$\begin{aligned} \tau_{i,\text{eff}} &= \tau_i + \tau_D \\ \tau_{D,\text{eff}} &= \frac{1}{1/\tau_D + 1/\tau_i} \\ K_c &= \frac{100}{P} \left( 1 + \frac{\tau_D}{\tau_i} \right) \end{aligned} \quad (8-32)$$

The performance of the interacting controller is almost as high as that of the noninteracting controller on most processes, but the tuning rules differ because of the above relationships. Both controllers are in common use in digital systems.

There is always a gain limit placed upon the derivative vector—a value of 10 is typical. However, interaction decreases the derivative

FIG. 8-24 Transition from well-damped load response to instability develops as loop gain increases.

FIG. 8-25 On/off controller characteristics.

gain below this value by the factor  $1 + \tau_D/\tau_I$ , which is the reason for the decreased performance of the interacting PID controller. Sampling in a digital controller has a similar effect, limiting derivative gain to the ratio of derivative time to the sample interval of the controller. Noise on the controlled variable is amplified by the derivative gain, preventing its use in controlling flow and liquid level. Derivative action is recommended for control of temperature and composition in multiple-capacity processes with little measurement noise.

**Controller Comparison** Figure 8-26 compares the step load response of a distributed lag without control, and with P, PI, and interacting PID control. A distributed lag is a process whose resistance and capacity are distributed throughout its length—a heat exchanger is characteristic of this class, its heat-transfer surface and heat capacity being uniformly distributed. Other examples include imperfectly stirred tanks and distillation columns—both trayed and packed. The signature of a distributed lag is its open-loop (uncontrolled) step response, featuring a relatively short dead time followed by a dominant lag called  $\Sigma\tau$ , which is the time required to reach 63.2 percent complete response.

The proportional controller is unable to return the controlled variable to the set point following the step load change, as a deviation is required to sustain its output at a value different from its fixed bias  $b$ . The amount of proportional offset produced as a fraction of the uncontrolled offset is  $1/(1 + KK_c)$ , where  $K$  is the steady-state process

gain—in Fig. 8-26, that fraction is 0.13. Increasing  $K_c$  can reduce the offset, but with an accompanying loss in damping.

The PI and PID controller were tuned to produce a minimum *integrated absolute error* (IAE). Their response curves are similar in appearance to a gaussian distribution curve, but with a damped cycle in the trailing edge. The peak deviation of the PID response curve is only 0.12 times the uncontrolled offset, occurring at  $0.36\Sigma\tau$ ; the peak deviation of the PI response curve is 0.21 times the uncontrolled offset, occurring at  $0.48\Sigma\tau$ . These values can be used to predict the load response of any distributed lag whose parameters  $K$  and  $\Sigma\tau$  are known or can be estimated as described below.

**CONTROLLER TUNING**

The performance of a controller depends as much on its tuning as on its design. Tuning must be applied by the end user to fit the controller to the controlled process. There are many different approaches to controller tuning, based on the particular performance criteria selected, whether load or set-point changes are more important, whether the process is lag- or dead-time-dominant, and the availability of information about the process dynamics. The earliest definitive work in this field was done at the Taylor Instrument Company by Ziegler and Nichols (*Trans. ASME*, p. 759, 1942), tuning PI and interacting PID

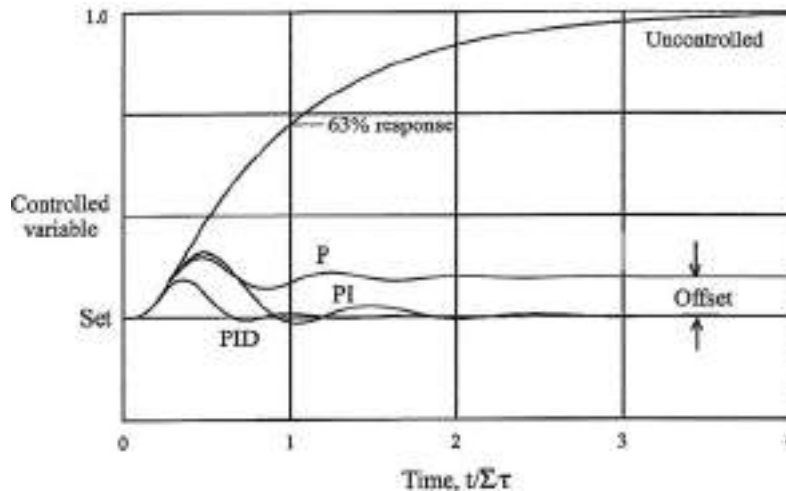

FIG. 8-26 Minimum-IAE tuning gives very satisfactory load response for a distributed lag.

controllers for optimum response to step load changes applied to lag-dominant processes. While these tuning rules are still in use, they do not apply to set-point changes, dead-time-dominant processes, or noninteracting PID controllers (Seborg, Edgar, and Mellichamp, *Process Dynamics and Control*, Wiley, New York, 2004).

**Controller Performance Criteria** The most useful measures of controller performance in an industrial setting are the maximum deviation in the controlled variable resulting from a disturbance, and its integral. The disturbance could be to the set point or to the load, depending on the variable being controlled and its context in the process. The size of the deviation and its integral are proportional to the size of the disturbance (if the loop is linear at the operating point). While actual disturbances arising in a plant may appear to be random, the controller needs a reproducible test to determine how well it is tuned. The disturbance of choice for test purposes is the step, because it can be applied manually, and by containing all frequencies including zero it exercises all modes of the controller. (The step actually has the same frequency distribution as integrated white noise, a “random walk.”) When tuned optimally for step disturbances, the controller will be optimally tuned for most other disturbances as well.

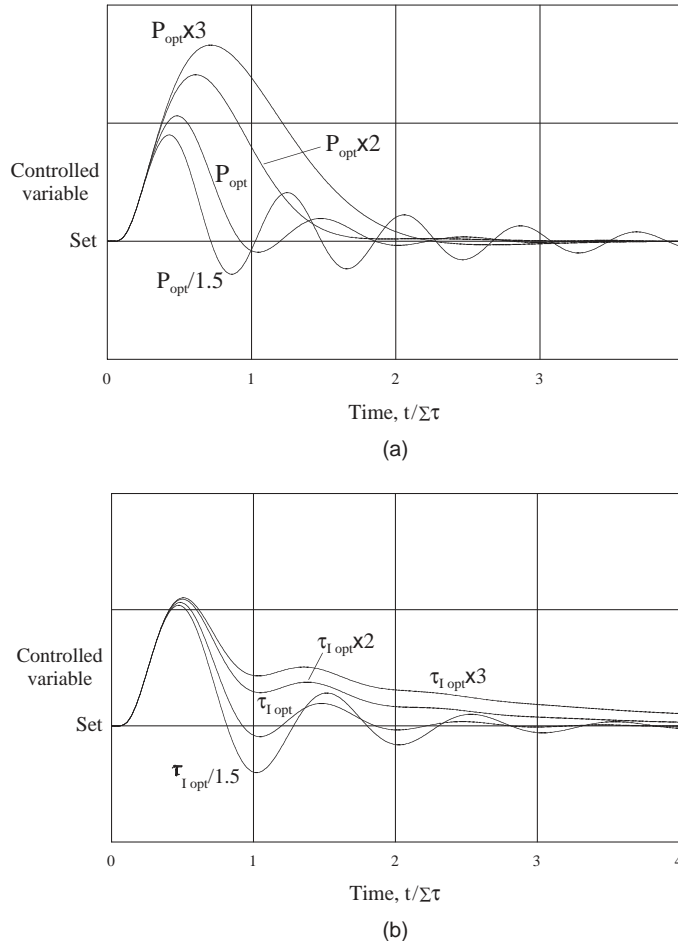

A step change in set point, however, may be a poor indicator of a loop’s load response. For example, a liquid-level controller does not have to integrate to follow a set-point change, as its steady-state output is independent of the set point. Stepping a flow controller’s set point is

an effective test of its tuning, however, as its steady-state output is proportional to its set point. Other loops should be load-tested: simulate a load change from a steady state at zero deviation by transferring the controller to manual and stepping its output, and then immediately transferring back to automatic before a deviation develops.

Figure 8-27*a* and *b* shows variations in the response of a distributed lag to a step change in load for different combinations of proportional and integral settings of a PI controller. The maximum deviation is the most important criterion for variables that could exceed safe operating levels, such as steam pressure, drum level, and steam temperature in a boiler. The same rule can apply to product quality if violating specifications causes it to be rejected. However, if the product can be accumulated in a downstream storage tank, its average quality is more important, and this is a function of the deviation integrated over the residence time of the tank. Deviation in the other direction, where the product is better than specification, is safe but increases production costs in proportion to the integrated deviation because quality is given away.

For a PI or PID controller, the integrated deviation—better known as integrated error IE—is related to the controller settings

$$IE = \Delta u \frac{P\tau_i}{100} \tag{8-33}$$

**FIG. 8-27** The optimum settings produce minimum-IAE load response. (a) The proportional band primarily affects damping and peak deviation. (b) Integral time determines overshoot.

where  $\Delta u$  is the difference in controller outputs between two steady states, as required by a change in load or set point. The proportional band  $P$  and integral time  $\tau_i$  are the indicated settings of the controller for PI and both interacting and noninteracting PID controllers. Although the derivative term does not appear in the relationship, its use typically allows a 50 percent reduction in integral time and therefore in IE. The integral time in the IE expression should be augmented by the sample interval if the controller is digital, the time constant of any filter used, and the value of any dead-time compensator.

It would appear, from the above, that minimizing IE is simply a matter of minimizing the  $P$  and  $\tau_i$  settings of the controller. However, settings will be reached that produce excessive oscillations, such as shown in the lowest two response curves in Fig. 8-27a and b. It is preferable instead to find a combination of controller settings that minimizes integrated absolute error IAE, which for both load and set-point changes is a well-damped response with minimal overshoot. The curves designated  $P_{opt}$  and  $\tau_{i,opt}$  in Fig. 8-27 are the same minimum-IAE response to a step change in load for a distributed-lag process under PI control. Because of the very small overshoot, the IAE will be only slightly larger than the IE. Loops that are tuned to minimize IAE tend to give responses that are close to minimum IE and with minimum peak deviation. The other curves in Fig. 8-27a and b describe the effects of individual adjustments to  $P$  and  $\tau_i$ , respectively, around those optimum values and can serve as a guide to fine-tuning a PI controller.

The performance of a controller (and its tuning) must be based on what is achievable for a given process. The concept of best practical IE ( $IE_b$ ) for a step change in load  $\Delta L$  to a process consisting of dead time and one or two lags can be estimated (Shinskey, *Process Control Systems*, 4th ed., McGraw-Hill, New York, 1996)

$$IE_b = \Delta L K_L \tau_L (1 - e^{-\theta/\tau_L}) \quad (8-34)$$

where  $K_L$  is the gain and  $\tau_L$  the primary time constant in the load path, and  $\theta$  the dead time in the manipulated path to the controlled variable. If the load or its gain is unknown,  $\Delta u$  and  $\bar{K} (= K_L K_p)$  may be substituted. If the process is non-self-regulating (i.e., an integrator), the relationship is

$$IE_b = \frac{\Delta L \theta^2}{\tau_i} \quad (8-35)$$

where  $\tau_i$  is the time constant of the process integrator. The peak deviation of the best practical response curve is

$$e_b = \frac{IE_b}{\theta + \tau_2} \quad (8-36)$$

where  $\tau_2$  is the time constant of a common secondary lag (e.g., in the measuring device).

TABLE 8-2 Tuning Rules Using Known Process Parameters

| Process             | Controller       | $P$                  | $\tau_i$          | $\tau_D$          |
|---------------------|------------------|----------------------|-------------------|-------------------|
| Dead-time-dominant  | PI               | 250K                 | 0.5 $\theta$      |                   |
| Lag-dominant        | PI               | 106K $\theta/\tau_m$ | 4.0 $\theta$      |                   |
|                     | PID <sub>n</sub> | 77K $\theta/\tau_m$  | 1.8 $\theta$      | 0.45 $\theta$     |
|                     | PID <sub>i</sub> | 106K $\theta/\tau_m$ | 1.5 $\theta$      | 0.55 $\theta$     |
| Non-self-regulating | PI               | 106 $\theta/\tau_i$  | 4.0 $\theta$      |                   |
|                     | PID <sub>n</sub> | 78 $\theta/\tau_i$   | 1.9 $\theta$      | 0.48 $\theta$     |
|                     | PID <sub>i</sub> | 108 $\theta/\tau_i$  | 1.6 $\theta$      | 0.58 $\theta$     |
| Distributed lags    | PI               | 20K                  | 0.50 $\Sigma\tau$ |                   |
|                     | PID <sub>n</sub> | 10K                  | 0.30 $\Sigma\tau$ | 0.09 $\Sigma\tau$ |
|                     | PID <sub>i</sub> | 15K                  | 0.25 $\Sigma\tau$ | 0.10 $\Sigma\tau$ |

NOTE:  $n$  = noninteracting,  $i$  = interacting controller modes.

The performance of any controller can be measured against this standard by comparing the IE it achieves in responding to a load change with the best practical IE. Maximum performance levels for PI controllers on lag-dominant processes lie in the 20 to 30 percent range, while for PID controllers they fall between 40 and 60 percent, varying with secondary lags.

**Tuning Methods Based on Known Process Models** The most accurate tuning rules for controllers have been based on simulation, where the process parameters can be specified and IAE and IE can be integrated during the simulation as an indication of performance. Controller settings are then iterated until a minimum IAE is reached for a given disturbance. Next these optimum settings are related to the parameters of the simulated process in tables, graphs, or equations, as a guide to tuning controllers for processes whose parameters are known (Seborg, Edgar, and Mellichamp, *Process Dynamics and Control*, Wiley, New York, 2004). This is a multidimensional problem, however, in that the relationships change as a function of process type, controller type, and source of disturbance.

Table 8-2 summarizes these rules for minimum-IAE load response for the most common controllers. The process gain and time constant  $\tau_m$  are obtained from the product of  $G_v$  and  $G_p$  in Fig. 8-23. Derivative action is not effective for dead-time-dominant processes. Any secondary lag, sampling interval, or filter time constant should be added to dead time  $\theta$ .

The principal limitation to using these rules is that the true process parameters are often unknown. Steady-state gain  $K$  can be calculated from a process model, or determined from the steady-state results of a step test as  $\Delta c/\Delta u$ , as shown in Fig. 8-28. The test will not be viable, however if the time constant of the process  $\tau_m$  is longer than a few minutes, since five time constants must elapse to approach a steady state within 1 percent, and unexpected disturbances may intervene. Estimated dead time  $\theta$  is the time from the step to the intercept of a

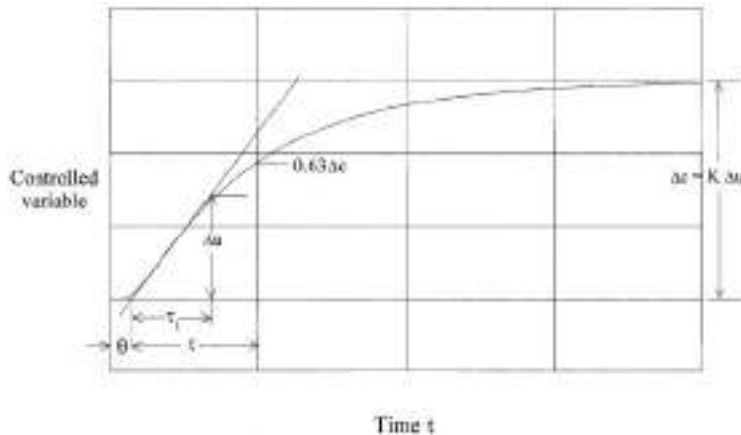

FIG. 8-28 If a steady state can be reached, gain  $K$  and time constant  $\tau$  can be estimated from a step response; if not, use  $\tau_i$  instead.

**TABLE 8-3 Tuning Rules Using Slope and Intercept**

| Controller       | $P$                | $\tau_i$     | $\tau_D$      |
|------------------|--------------------|--------------|---------------|
| PI               | $150\theta/\tau_1$ | 3.5 $\theta$ |               |
| PID <sub>n</sub> | $75\theta/\tau_1$  | 2.1 $\theta$ | 0.63 $\theta$ |
| PID <sub>i</sub> | $113\theta/\tau_1$ | 1.8 $\theta$ | 0.7 $\theta$  |

NOTE:  $n$  = noninteracting,  $i$  = interacting controller modes.

straight line tangent to the steepest part of the response curve. The estimated time constant  $\tau$  is the time from that point to 63 percent of the complete response. In the presence of a significant secondary lag, these results will not be completely accurate, however. The time for 63 percent response may be more accurately calculated as the residence time of the process: its volume divided by current volumetric flow rate.

**Tuning Methods When Process Model Is Unknown** Ziegler and Nichols developed two tuning methods for processes with unknown parameters. The open-loop method uses a step test without waiting for a steady state to be reached and is therefore applicable to very slow processes. Dead time is estimated from the intercept of the steepest tangent to the response curve in Fig. 8-28, whose slope is also used. If the process is non-self-regulating, the controlled variable will continue to follow this slope, changing by an amount equal to  $\Delta u$  in a time equal to its time constant  $\tau_1$ . This time estimate  $\tau_1$  is used along with  $\theta$  to tune controllers according to Table 8-3, applicable to lag-dominant processes. If the process is known to be a distributed lag, such as a heat exchanger, distillation column, or stirred tank, then better results will be obtained by converting the estimated values of  $\theta$  and  $\tau_1$  to  $K$  and  $\Sigma\tau$  and using Table 8-2. The conversion factors are  $K = 7.5\theta/\tau_1$  and  $\Sigma\tau = 7.0\theta$ .

The Ziegler and Nichols closed-loop method requires forcing the loop to cycle uniformly under proportional control, by setting the integral time to maximum and derivative time to zero and reducing the proportional band until a constant-amplitude cycle results. The natural period  $\tau_p$  of the cycle (the proportional controller contributes no phase shift to alter it) is used to set the optimum integral and derivative time constants. The optimum proportional band is set relative to the undamped proportional band  $P_u$  which was found to produce the uniform oscillation. Table 8-4 lists the tuning rules for a lag-dominant process.

A uniform cycle can also be forced by using on-off control to cycle the manipulated variable between two limits. The period of the cycle will be close to  $\tau_p$  if the cycle is symmetric; the peak-to-peak ampli-

**TABLE 8-4 Tuning Rules Using Proportional Cycle**

| Controller       | $P$       | $\tau_i$     | $\tau_D$     |
|------------------|-----------|--------------|--------------|
| PI               | $1.70P_u$ | $0.81\tau_p$ |              |
| PID <sub>n</sub> | $1.30P_u$ | $0.48\tau_p$ | $0.11\tau_p$ |
| PID <sub>i</sub> | $1.80P_u$ | $0.38\tau_p$ | $0.14\tau_p$ |

NOTE:  $n$  = noninteracting,  $i$  = interacting controller modes.

tude  $A_c$  of the controlled variable divided by the difference between the output limits  $A_u$  is a measure of process gain at that period and is therefore related to  $P_u$  for the proportional cycle:

$$P_u = 100 \frac{\pi}{4} \frac{A_c}{A_u} \tag{8-37}$$

The factor  $\pi/4$  compensates for the square wave in the output. Tuning rules are given in Table 8-4.

**Set-Point Response** All the above tuning methods are intended to minimize IAE for step load changes. When applied to lag-dominant processes, the resulting controller settings produce excessive overshoot of set-point changes. This behavior has led to the practice of tuning to optimize set-point response, which unfortunately degrades the load response of lag-dominant loops. An option has been available with some controllers to remove proportional action from set-point changes, which eliminates set-point overshoot but lengthens settling time. A preferred solution to this dilemma is available in many modern controllers which feature an independent gain adjustment for the set point, through which set-point response can be optimized after the controller has been tuned to optimize load response.

Figure 8-29 shows set-point and load responses of a distributed lag for both set-point and load tuning, including the effects of fractional set-point gain  $K_s$ . The set point was stepped at time zero, and the load stepped at time 2.4. With full set-point gain, the PI controller was tuned for minimum-IAE set-point response with  $P = 29K$  and  $\tau_i = \Sigma\tau$ , compared to  $P = 20K$  and  $\tau_i = 0.50\Sigma\tau$  for minimum-IAE load response. These settings increase its IE for load response by a factor of 2.9, and its peak deviation by 20 percent, over optimum load tuning. However, with optimum load tuning, that same set-point overshoot can be obtained with set-point gain  $K_s = 0.54$ . The effects of full set-point gain (1.0) and no set-point gain (0) are shown for comparison.

**FIG. 8-29** Tuning proportional and integral settings to optimize set-point response degrades load response; using a separate set-point gain adjustment allows both responses to be optimized.

## ADVANCED CONTROL SYSTEMS

## BENEFITS OF ADVANCED CONTROL

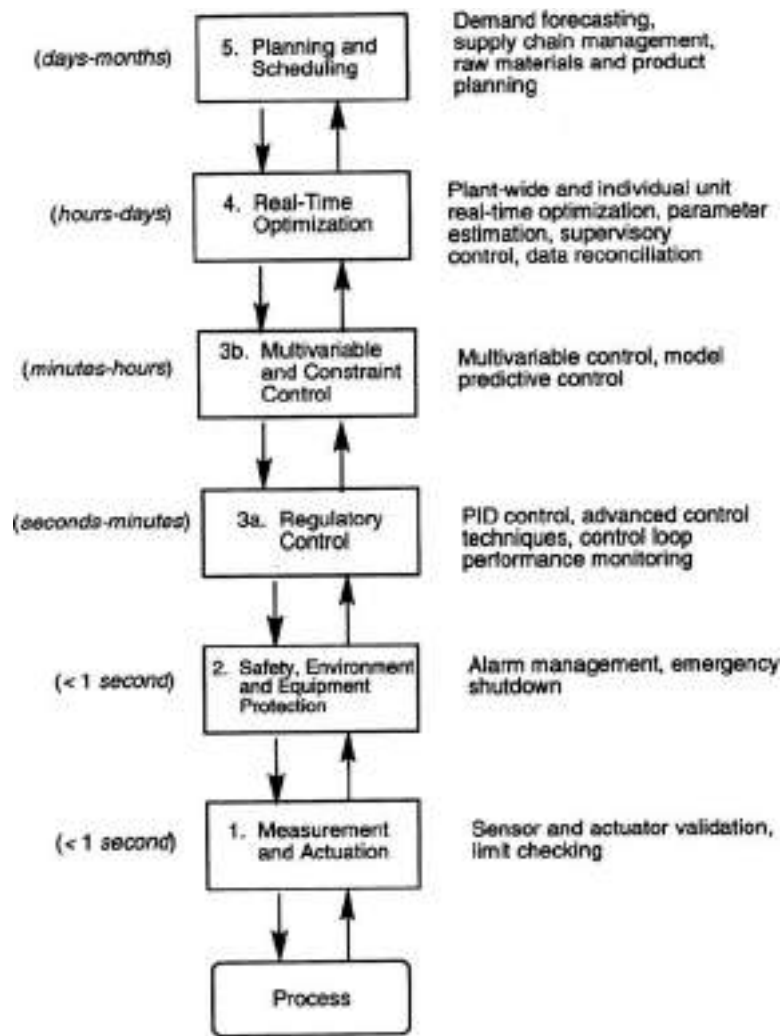

The economics of most processes are determined by the steady-state operating conditions. Excursions from these steady-state conditions usually have a less important effect on the economics of the process, except when the excursions lead to off-specification products. To enhance the economic performance of a process, the steady-state operating conditions must be altered in a manner that leads to more efficient process operation.

The hierarchy shown in Fig. 8-30 indicates that process control activities consist of the following five levels:

- Level 1: Measurement devices and actuators
- Level 2: Safety, environmental/equipment protection
- Level 3: Regulatory control
- Level 4: Real-time optimization
- Level 5: Planning and scheduling

Levels 4 and 5 clearly affect the process economics, as both levels are directed to optimizing the process in some manner. In contrast, levels 1, 2, and 3 would appear to have no effect on process economics. Their direct effect is indeed minimal, although indirectly they can have a major effect. Basically, these levels provide the foundation for all higher levels. A process cannot be optimized until it can be operated consistently at the prescribed targets. Thus, satisfactory regulatory control must be the first goal of any automation effort. In turn, the measurements and actuators provide the process interface for regulatory control.

For most processes, the optimum operating point is determined by a constraint. The constraint might be a product specification (a product stream can contain no more than 2 percent ethane); violation of this constraint causes off-specification product. The constraint might be an equipment limit (vessel pressure rating is 300 psig); violation of this constraint causes the equipment protection mechanism (pressure

**FIG. 8-30** The five levels of process control and optimization in manufacturing. Time scales are shown for each level. (Source: *Seborg et al., Process Dynamics and Control, 2d ed., Wiley, New York, 2004.*)

relief device) to activate. As the penalties are serious, violation of such constraints must be very infrequent.

If the regulatory control system were perfect, the target could be set exactly equal to the constraint (i.e., the target for the pressure controller could be set at the vessel relief pressure). However, no regulatory control system is perfect. Therefore, the value specified for the target must be on the safe side of the constraint, thus allowing the control system some operating margin. How much depends on the following:

1. The performance of the control system (i.e., how effectively it responds to disturbances). The faster the control system reacts to a disturbance, the closer the process can be operated to the constraint.

2. The magnitude of the disturbances to which the control system must respond. If the magnitude of the major disturbances can be reduced, the process can be operated closer to the constraint.

One measure of the performance of a control system is the variance of the controlled variable from the target. Both improving the control system and reducing the disturbances will lead to a lower variance in the controlled variable.

In a few applications, improving the control system leads to a reduction in off-specification product and thus improved process economics. However, in most situations, the process is operated sufficiently far from the constraint that very little, if any, off-specification product results from control system deficiencies. Management often places considerable emphasis on avoiding off-specification production, so consequently the target is actually set far more conservatively than it should be.

In most applications, simply improving the control system does not directly lead to improved process economics. Instead, the control system improvement must be accompanied by shifting the target closer to the constraint. There is always a cost of operating a process in a conservative manner. The cost may be a lower production rate, a lower process efficiency, a product giveaway, or other. When management places undue emphasis on avoiding off-specification production, the natural reaction is to operate very conservatively, thus incurring other costs.

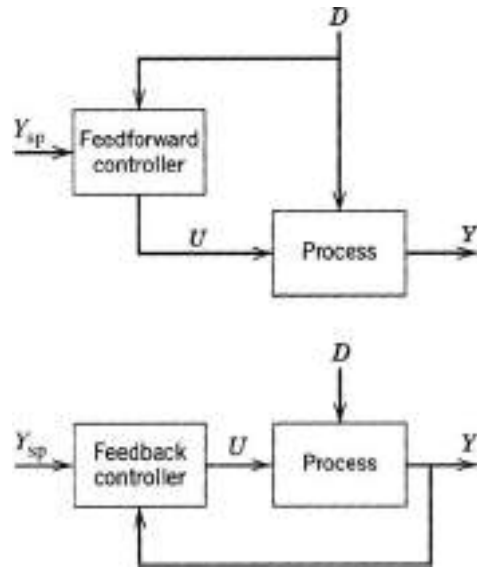

The immediate objective of an advanced control effort is to reduce the variance in an important controlled variable. However, this effort must be coupled with a commitment to adjust the target for this controlled variable so that the process is operated closer to the constraint. In large-throughput (commodity) processes, very small shifts in operating targets can lead to large economic returns.

**ADVANCED CONTROL TECHNIQUES**

**GENERAL REFERENCES:** Seborg, Edgar, and Mellichamp, *Process Dynamics and Control*, Wiley, New York, 2004. Stephanopoulos, *Chemical Process Control: An Introduction to Theory and Practice*, Prentice-Hall, Englewood Cliffs, N.J., 1984. Shinskey, *Process Control Systems*, 4th ed., McGraw-Hill, New York, 1996. Ogunmaike and Ray, *Process Dynamics, Modeling, and Control*, Oxford University Press, New York, 1994.

While the single-loop PID controller is satisfactory in many process applications, it does not perform well for processes with slow dynamics, time delays, frequent disturbances, or multivariable interactions. We discuss several advanced control methods below that can be implemented via computer control, namely, feedforward control, cascade control, time-delay compensation, selective and override control, adaptive control, fuzzy logic control, and statistical process control.

**Feedforward Control** If the process exhibits slow dynamic response and disturbances are frequent, then the application of feedforward control may be advantageous. Feedforward (FF) control differs from feedback (FB) control in that the primary disturbance or load (*D*) is measured via a sensor and the manipulated variable (*U*) is adjusted so that deviations in the controlled variable from the set point are minimized or eliminated (see Fig. 8-31). By taking control action based on measured disturbances rather than controlled variable error, the controller can reject disturbances before they affect the controlled variable *Y*. To determine the appropriate settings for the manipulated variable, one must develop mathematical models that relate

**FIG. 8-31** Simplified block diagrams for feedforward and feedback control.

1. The effect of the manipulated variable *U* on the controlled variable *Y*
2. The effect of the disturbance *D* on the controlled variable *Y*

These models can be based on steady-state or dynamic analysis. The performance of the feedforward controller depends on the accuracy of both models. If the models are exact, then feedforward control offers the potential of perfect control (i.e., holding the controlled variable precisely at the set point at all times because of the ability to predict the appropriate control action). However, since most mathematical models are only approximate and since not all disturbances are measurable, it is standard practice to utilize feedforward control in conjunction with feedback control. Table 8-5 lists the relative advantages and disadvantages of feedforward and feedback control. By combining the two control methods, the strengths of both schemes can be utilized.

FF control therefore attempts to eliminate the effects of measurable disturbances, while FB control would correct for unmeasurable disturbances and modeling errors. This latter case is often referred to as feedback trim. These controllers have become widely accepted in the chemical process industries since the 1960s.

**Design Based on Material and Energy Balances** Consider a heat exchanger example (see Fig. 8-32) to illustrate the use of FF and FB control. The control objective is to maintain *T*<sub>2</sub>, the exit liquid temperature, at the desired value (or set point) *T*<sub>2sp</sub> despite variations in the inlet liquid flow rate *F* and inlet liquid temperature *T*<sub>1</sub>. This is done by manipulating *W*, the steam flow rate. A feedback control scheme would entail measuring *T*<sub>2</sub>, comparing *T*<sub>2</sub> to *T*<sub>2sp</sub>, and then adjusting *W*. A feedforward control scheme requires measuring *F* and *T*<sub>1</sub>, and adjusting *W* (knowing *T*<sub>2sp</sub>), in order to control exit temperature *T*<sub>2</sub>.

Figure 8-33*a* and *b* shows the control system diagrams for FB and FF control. A feedforward control algorithm can be designed for the heat exchanger in the following manner. Using a steady-state energy balance and assuming no heat loss from the heat exchanger,

$$WH = FC(T_2 - T_1) \tag{8-38}$$

where *H* = latent heat of vaporization and *C* = specific heat of liquid

$$W = \frac{C}{H} F(T_2 - T_1) \tag{8-39}$$

or

$$W = K_1 F(T_2 - T_1) \tag{8-40}$$

**TABLE 8-5 Relative Advantages and Disadvantages of Feedforward and Feedback**

| Advantages  | Disadvantages  |
|---|--|
| Feedforward   |  |
| <ul style="list-style-type: none"> <li>• Acts before the effect of a disturbance has been felt by the system</li> <li>• Is good for systems with large time constant or dead time</li> <li>• Does not introduce instability in the closed-loop response</li> </ul>                  | <ul style="list-style-type: none"> <li>• Requires direct measurement of all possible disturbances</li> <li>• Cannot cope with unmeasured disturbances</li> <li>• Is sensitive to process/model error</li> </ul>  |
| Feedback  |  |
| <ul style="list-style-type: none"> <li>• Does not require identification and measurement of any disturbance for corrective action</li> <li>• Does not require an explicit process model</li> <li>• Is possible to design controller to be robust to process/model errors</li> </ul> | <ul style="list-style-type: none"> <li>• Control action not taken until the effect of the disturbance has been felt by the system</li> <li>• Is unsatisfactory for processes with large time constants and frequent disturbances</li> <li>• May cause instability in the closed-loop response</li> </ul> |

with

$$K_1 = \frac{C_L}{H} \tag{8-41}$$

Replace  $T_2$  by  $T_{2sp}$

$$W = K_1 F (T_{set} - T_1) \tag{8-42}$$

Equation (8-42) can be used in the FF calculation, assuming one knows the physical properties  $C$  and  $H$ . Of course, it is probable that the model will contain errors (e.g., unmeasured heat losses, incorrect  $C$  or  $H$ ). Therefore,  $K_1$  can be designated as an adjustable parameter that can be tuned. The use of a physical model for FF control is desirable because it provides a physical basis for the control law and gives an a priori estimate of what the tuning parameters should be. Note that such a model could be nonlinear [e.g., in Eq. (8-42),  $F$  and  $T_{2sp}$  are multiplied].

**Block Diagram Analysis** One shortcoming of this feedforward design procedure is that it is based on the steady-state characteristics of the process and, as such, neglects process dynamics (i.e., how fast the controlled variable responds to changes in the load and manipulated variables). Thus, it is often necessary to include “dynamic compensation” in the feedforward controller. The most direct method of designing the FF dynamic compensator is to use a block diagram of a general process, as shown in Fig. 8-34, where  $G_d$  represents the disturbance transmitter,  $G_f$  is the feedforward controller,  $G_v$  relates the disturbance to the controlled variable,  $G_c$  is the valve,  $G_p$  is the process,  $G_m$  is the output transmitter, and  $G_e$  is the feedback controller. All blocks correspond to transfer functions (via Laplace transforms).

Using block diagram algebra and Laplace transform variables, the controlled variable  $Y(s)$  is given by

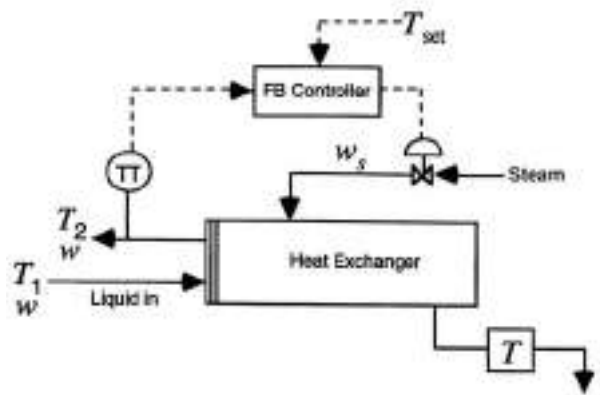

$$Y(s) = \frac{G_f G_d L(s) + G_d D(s)}{1 + G_m G_c G_e G_p} \tag{8-43}$$

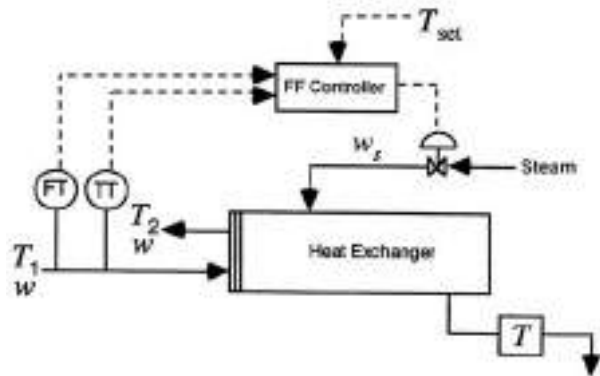

**FIG. 8-32** A heat exchanger diagram.

For disturbance rejection [ $D(s) \neq 0$ ] we require that  $Y(s) = 0$ , or zero error. Solving Eq. (8-43) for  $G_f$  gives

$$G_f = \frac{-G_d}{G_c G_e G_p} \tag{8-44}$$

(a)

(b)

**FIG. 8-33** (a) Feedback control of a heat exchanger. (b) Feedforward control of a heat exchanger.

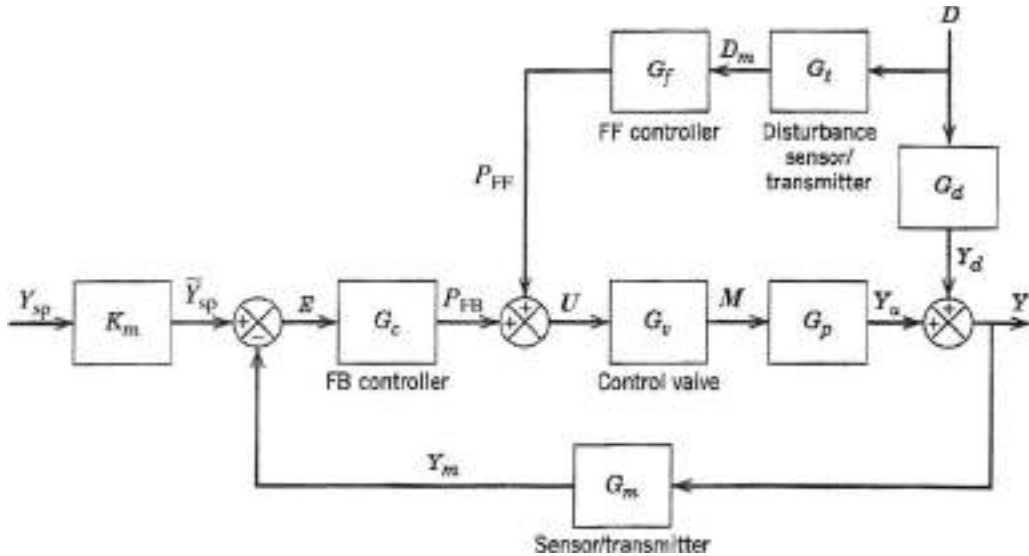

FIG. 8-34 A block diagram of a feedforward-feedback control system. (Source: Seborg et al., Process Dynamics and Control, 2d ed., Wiley, New York, 2004.)

Suppose the dynamics of  $G_d$  and  $G_p$  are first-order; in addition, assume that  $G_c = K_c$  and  $G_t = K_t$  (constant gains for simplicity).

$$G_d(s) = \frac{K_d}{\tau_d s + 1} = \frac{Y(s)}{D(s)} \tag{8-45}$$

$$G_p(s) = \frac{K_p}{\tau_p s + 1} = \frac{Y(s)}{U(s)} \tag{8-46}$$

Using Eq. (8-44),

$$G_f(s) = \frac{\tau_p s + 1}{\tau_d s + 1} \cdot \frac{-K_d}{K_p K_c K_t} = \frac{-K(\tau_p s + 1)}{\tau_d s + 1} \tag{8-47}$$

where  $K$  is the overall ratio of the gains in Eq. (8-47).

The above FF controller can be implemented by using a digital computer. Figure 8-35*a* and *b* compares typical responses for PID FB control, steady-state FF control ( $s = 0$ ), dynamic FF control, and combined FF/FB control. In practice, the engineer can tune  $K$ ,  $\tau_p$ , and  $\tau_d$  in the field to improve the performance of the FF controller. The feedforward controller can also be simplified to provide steady-state feedforward control. This is done by setting  $s = 0$  in  $G_f(s)$ . This might be appropriate if there is uncertainty in the dynamic models for  $G_d$  and  $G_p$ .

**Other Considerations in Feedforward Control** The tuning of feedforward and feedback control systems can be performed independently. In analyzing the effects of the disturbance  $D(s)$ , as long as there are no model errors. For the feedback loop, therefore, the effects of  $D(s)$  can also be ignored, which for the servo case is

$$\frac{Y(s)}{Y_{sp}(s)} = \frac{G_c G_c G_p K_m}{1 + G_c G_c G_p G_m} \tag{8-48}$$

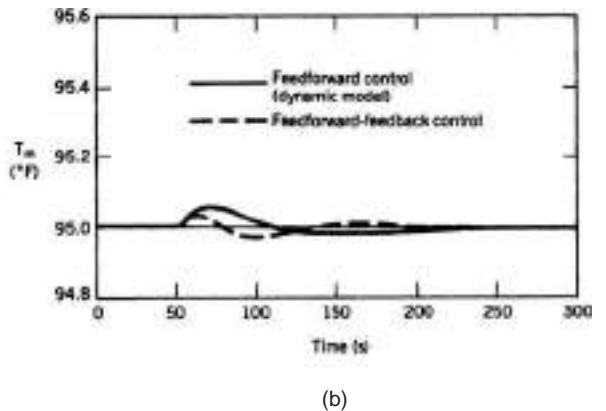

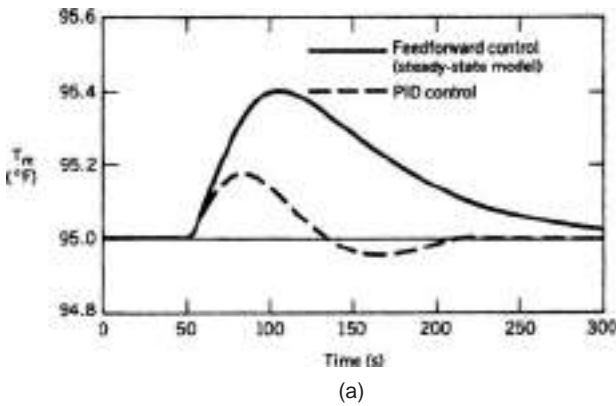

FIG. 8-35 (a) Comparison of FF (steady-state model) and PID FB control for disturbance change. (b) Comparison of FF (dynamic model) and combined FF/FB control.

FIG. 8-36 Cascade control of an exothermic chemical reactor. (Source: Seborg et al., *Process Dynamics and Control*, 2d ed., Wiley, New York, 2004.)

Note that the characteristic equation will be unchanged for the FF + FB system; hence system stability will be unaffected by the presence of the FF controller. In general, the tuning of the FF controller can be less conservative than for the case of FB alone, because smaller excursions from the set point will result. This in turn would make the dynamic model  $Y(s)$  more accurate.

The tuning of the controller in the feedback loop can be theoretically performed independently of the feedforward loop (i.e., the feedforward loop does not introduce instability in the closed-loop response). For more information on feedforward/feedback control applications and design of such controllers, refer to the general references.

**Cascade Control** One of the disadvantages of using conventional feedback control for processes with large time lags or delays is that disturbances are not recognized until after the controlled variable deviates from its set point. In these processes, correction by feedback control is generally slow and results in long-term deviation from the set point. One way to improve the dynamic response to load changes is by using a secondary measurement point and a secondary controller; the secondary measurement point is located so that it recognizes the upset condition before the primary controlled variable is affected.

One such approach is called cascade control, which is routinely used in most modern computer control systems. Consider a chemical reactor, where reactor temperature is to be controlled by coolant flow to the jacket of the reactor. The reactor temperature can be influenced by changes in disturbance variables such as feed rate or feed temperature; a feedback controller could be employed to compensate for such disturbances by adjusting a valve on the coolant flow to the reactor jacket. However, suppose an increase occurs in the coolant temperature as a result of changes in the plant coolant system. This will cause a change in the reactor temperature measurement, although such a change will not occur quickly, and the corrective action taken by the controller will be delayed.

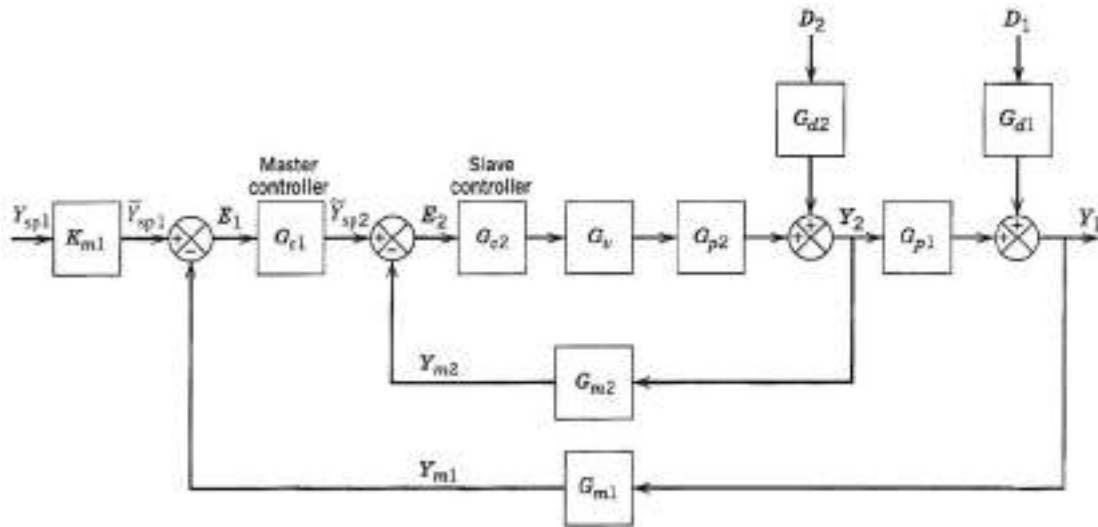

Cascade control is one solution to this problem (see Fig. 8-36). Here the jacket temperature is measured, and an error signal is sent from this point to the coolant control valve; this reduces coolant flow,

maintaining the heat-transfer rate to the reactor at a constant level and rejecting the disturbance. The cascade control configuration will also adjust the setting of the coolant control valve when an error occurs in the reactor temperature. The cascade control scheme shown in Fig. 8-36 contains two controllers. The primary controller is the reactor temperature controller. It measures the reactor temperature, compares it to the set point, and computes an output, which is the set point for the coolant flow rate controller. The secondary controller compares this set point to the coolant temperature measurement and adjusts the valve. The principal advantage of cascade control is that the secondary measurement (jacket temperature) is located closer to a potential disturbance in order to improve the closed-loop response.

Figure 8-37 shows the block diagram for a general cascade control system. In tuning of a cascade control system, the secondary controller (in the inner loop) is tuned first with the primary controller in manual. Often only a proportional controller is needed for the secondary loop, because offset in the secondary loop can be treated by using proportional-plus-integral action in the primary loop. When the primary controller is transferred to automatic, it can be tuned by using the techniques described earlier in this section. For more information on theoretical analysis of cascade control systems, see the general references for a discussion of applications of cascade control.

**Time-Delay Compensation** Time delays are a common occurrence in the process industries because of the presence of recycle loops, fluid-flow distance lags, and dead time in composition measurements resulting from use of chromatographic analysis. The presence of a time delay in a process severely limits the performance of a conventional PID control system, reducing the stability margin of the closed-loop control system. Consequently, the controller gain must be reduced below that which could be used for a process without delay. Thus, the response of the closed-loop system will be sluggish compared to that of the system with no time delay.

To improve the performance of time-delay systems, special control algorithms have been developed to provide time-delay compensation. The Smith predictor technique is the best-known algorithm; a related method is called the analytical predictor. Various investigators have

**FIG. 8-37** Block diagram of the cascade control system. For a chemical reactor  $G_{d1}$  would correspond to a feed temperature or composition disturbance, while  $G_{d2}$  would be a change in the cooling water temperature. (Source: Seborg et al., Process Dynamics and Control, 2d ed., Wiley, New York, 2004.)

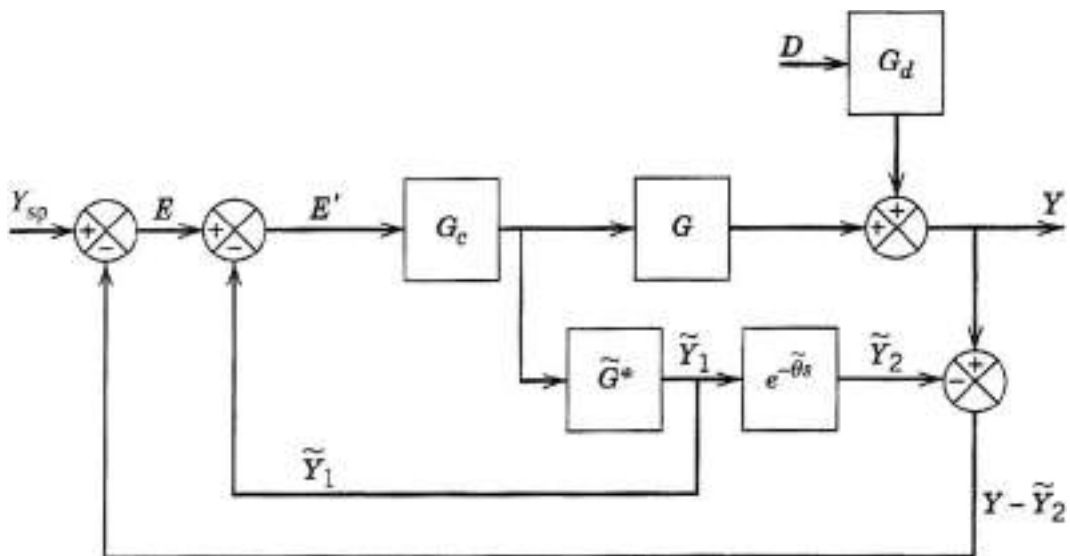

found that, based on integral squared error, the performance of the Smith predictor can be better than that for a conventional controller, as long as the time delay is known accurately.

The Smith predictor is a model-based control strategy that involves a more complicated block diagram than that for a conventional feedback controller, although a PID controller is still central to the control strategy (see Fig. 8-38). The key concept is based on better coordination of the timing of manipulated variable action. The loop configuration takes into account the fact that the current controlled variable measurement is not a result of the current manipulated variable action, but the value taken  $\theta$  time units earlier. Time-delay compensation can yield excellent performance; however, if the process model parameters change (especially the time delay), the Smith predictor

performance will deteriorate and is not recommended unless other precautions are taken.

**Selective and Override Control** When there are more controlled variables than manipulated variables, a common solution to this problem is to use a selector to choose the appropriate process variable from among a number of available measurements. Selectors can be based on multiple measurement points, multiple final control elements, or multiple controllers, as discussed below. Selectors are used to improve the control system performance as well as to protect equipment from unsafe operating conditions.

One type of selector device chooses as its output signal the highest (or lowest) of two or more input signals. This approach is often referred to as auctioneering. On instrumentation diagrams, the symbol

**FIG. 8-38** Block diagram of the Smith predictor. (Source: Seborg et al., Process Dynamics and Control, 2d ed., Wiley, New York, 2004.)

> denotes a high selector and < a low selector. For example, a high selector can be used to determine the hot-spot temperature in a fixed-bed chemical reactor. In this case, the output from the high selector is the input to the temperature controller. In an exothermic catalytic reaction, the process may run away due to disturbances or changes in the reactor. Immediate action should be taken to prevent a dangerous rise in temperature. Because a hot spot may potentially develop at one of several possible locations in the reactor, multiple (redundant) measurement points should be employed. This approach minimizes the time required to identify when a temperature has risen too high at some point in the bed.

The use of high or low limits for process variables is another type of selective control, called an override. The feature of antireset windup in feedback controllers is a type of override. Another example is a distillation column with lower and upper limits on the heat input to the column reboiler. The minimum level ensures that liquid will remain on the trays, while the upper limit is determined by the onset of flooding. Overrides are also used in forced-draft combustion control systems to prevent an imbalance between airflow and fuel flow, which could result in unsafe operating conditions.

Other types of selective systems employ multiple final control elements or multiple controllers. In some applications, several manipulated variables are used to control a single process variable (also called split-range control). Typical examples include the adjustment of both inflow and outflow from a chemical reactor to control reactor pressure or the use of both acid and base to control pH in wastewater treatment. In this approach, the selector chooses among several controller outputs which final control element should be adjusted.

**Adaptive Control** Process control problems inevitably require online tuning of the controller constants to achieve a satisfactory degree of control. If the process operating conditions or the environment changes significantly, the controller may have to be retuned. If these changes occur quite frequently, then adaptive control techniques should be considered. An adaptive control system is one in which the controller parameters are adjusted automatically to compensate for changing process conditions.

The subject of adaptive control is one of current interest. New algorithms continue to be developed, but these need to be field-tested before industrial acceptance can be expected. An adaptive controller is inherently nonlinear and therefore more complicated than the conventional PID controller.

**Fuzzy Logic Control** The application of fuzzy logic to process control requires the concepts of fuzzy rules and fuzzy inference. A fuzzy rule, also known as a fuzzy IF-THEN statement, has the form

If  $x$  then  $y$   
 if input1 = high  
 and input2 = low  
 then output = medium

Three functions are required to perform logical inferencing with fuzzy rules. The fuzzy AND is the product of a rule's input membership values, generating a weight for the rule's output. The fuzzy OR is a normalized sum of the weights assigned to each rule that contributes to a particular decision. The third function used is defuzzification, which generates a crisp final output. In one approach, the crisp output is the weighted average of the peak element values.

With a single feedback control architecture, information that is readily available to the algorithm includes the error signal, difference between the process variable and the set-point variable, change in error from previous cycles to the current cycle, changes to the set-point variable, change of the manipulated variable from cycle to cycle, and change in the process variable from past to present. In addition, multiple combinations of the system response data are available. As long as the irregularity lies in that dimension wherein fuzzy decisions are being based or associated, the result should be enhanced performance. This enhanced performance should be demonstrated in both the transient and steady-state response. If the system tends to have

changing dynamic characteristics or exhibits nonlinearities, fuzzy logic control should offer a better alternative to using constant PID settings. Most fuzzy logic software begins building its information base during the autotune function. In fact, the majority of the information used in the early stages of system start-up comes from the autotune solutions.

In addition to single-loop process controllers, products that have benefited from the implementation of fuzzy logic are camcorders, elevators, antilock braking systems, and televisions with automatic color, brightness, and sound control. Sometimes fuzzy logic controllers are combined with pattern recognition software such as artificial neural networks (Passino and Yurkovich, *Fuzzy Control*, Addison-Wesley, Reading, Mass., 1998; Kosko, *Neural Networks and Fuzzy Systems*, Prentice-Hall, Englewood Cliffs, N.J., 1992).

## EXPERT SYSTEMS

An expert system is a computer program that uses an expert's knowledge in a particular domain to solve a narrowly focused, complex problem. An offline system uses information entered manually and produces results in visual form to guide the user in solving the problem at hand. An online system uses information taken directly from process measurements to perform tasks automatically or instruct or alert operating personnel to the status of the plant.

Each expert system has a rule base created by the expert to respond as the expert would to sets of input information. Expert systems used for plant diagnostics and management usually have an open rule base, which can be changed and augmented as more experience accumulates and more tasks are automated. The system begins as an empty shell with an assortment of functions such as equation solving, logic, and simulation, as well as input and display tools to allow an expert to construct a proprietary rule base. The "expert" in this case would be the person or persons having the deepest knowledge about the process, its problems, its symptoms, and remedies. Converting these inputs to meaningful outputs is the principal task in constructing a rule base. First-principles models (deep knowledge) produce the most accurate results, although heuristics are always required to establish limits. Often modeling tools such as artificial neural nets are used to develop relationships among the process variables.

A number of process control vendors offer comprehensive, object-oriented software environments for building and deploying expert systems. Advantages of such software include transforming complex real-time data to useful information through knowledge-based reasoning and analysis, monitoring for potential problems before they adversely impact operations, diagnosing root causes of time-critical problems to speed up resolution, and recommending or taking corrective actions to help ensure successful recovery.

## MULTIVARIABLE CONTROL

**GENERAL REFERENCES:** Shinsky, *Process Control Systems*, 4th ed., McGraw-Hill, New York, 1996. Seborg, Edgar, and Mellichamp, *Process Dynamics and Control*, 2d ed., Wiley, New York, 2004. McAvoy, *Interaction Analysis*, ISA, Research Triangle Park, N.C., 1983.

Process control books and journal articles tend to emphasize problems with a single controlled variable. In contrast, many processes require multivariable control with many process variables to be controlled. In fact, for virtually any important industrial process, at least two variables must be controlled: product quality and throughput. In this section, strategies for multivariable control are considered.

Three examples of simple multivariable control systems are shown in Fig. 8-39. The in-line blending system blends pure components  $A$  and  $B$  to produce a product stream with flow rate  $w$  and mass fraction of  $A$ ,  $x$ . Adjusting either inlet flow rate  $w_A$  or  $w_B$  affects both of the controlled variables  $w$  and  $x$ . For the pH neutralization process in Fig. 8-39b, liquid level  $h$  and exit stream pH are to be controlled by adjusting the acid and base flow rates  $w_A$  and  $w_B$ . Each of the manipulated variables affects both of the controlled variables. Thus, both the blending system and the pH neutralization process are said to exhibit

strong process interactions. In contrast, the process interactions for the gas-liquid separator in Fig. 8-39c are not as strong because one manipulated variable, liquid flow rate  $L$ , has only a small and indirect effect on one of the controlled variables, pressure  $P$ .

Strong process interactions can cause serious problems if a conventional multiloop feedback control scheme (e.g., either PI or PID controllers) is employed. The process interactions can produce undesirable control loop interactions where the controllers fight each other. Also, it may be difficult to determine the best pairing of controlled and manipulated variables. For example, in the in-line blending process in Fig. 8-39a, should  $w$  be controlled with  $w_A$  and  $x$  with  $w_B$ , or vice versa?

**Control Strategies for Multivariable Control** If a conventional multiloop control strategy performs poorly due to control loop interactions, a number of solutions are available:

1. Detune one or more of the control loops.
2. Choose different controlled or manipulated variables (or their pairings).

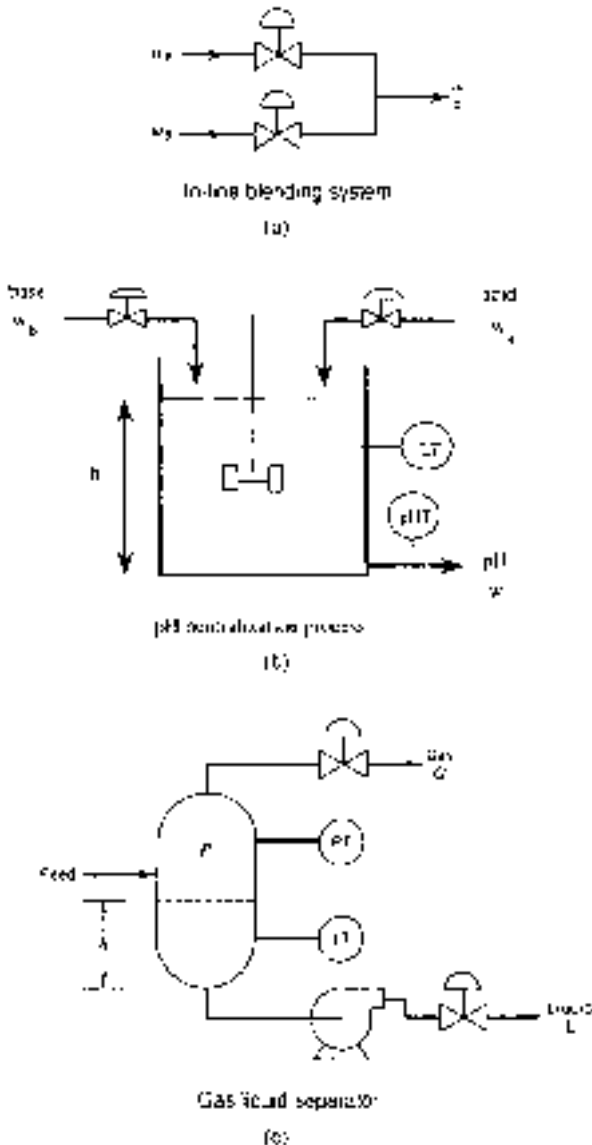

FIG. 8-39 Physical examples of multivariable control problems.

3. Use a decoupling control system.
4. Use a multivariable control scheme (e.g., model predictive control).

Detuning a controller (e.g., using a smaller controller gain or a larger reset time) tends to reduce control loop interactions by sacrificing the performance for the detuned loops. This approach may be acceptable if some of the controlled variables are faster or less important than others.

The selection of controlled and manipulated variables is of crucial importance in designing a control system. In particular, a judicious choice may significantly reduce control loop interactions. For the blending process in Fig. 8-39a, a straightforward control strategy would be to control  $x$  by adjusting  $w_A$ , and  $w$  by adjusting  $w_B$ . But physical intuition suggests that it would be better to control  $x$  by adjusting the ratio  $w_A/(w_A + w_B)$  and to control product flow rate  $w$  by the sum  $w_A + w_B$ . Thus, the new manipulated variables would be  $U_1 = w_A/(w_A + w_B)$  and  $U_2 = w_A + w_B$ . In this control scheme,  $U_1$  affects only  $x$ , and  $U_2$  affects only  $w$ . Thus, the control loop interactions have been eliminated. Similarly, for the pH neutralization process in Fig. 8-39b, the control loop interactions would be greatly reduced if pH were controlled by  $U_1 = w_A/(w_A + w_B)$  and liquid level  $h$  were controlled by  $U_2 = w_A + w_B$ .

**Decoupling Control Systems** Decoupling control systems provide an alternative approach for reducing control loop interactions. The basic idea is to use additional controllers called decouplers to compensate for undesirable process interactions.

As an illustrative example, consider the simplified block diagram for a representative decoupling control system shown in Fig. 8-40. The two controlled variables  $Y_1$  and  $Y_2$  and two manipulated variables  $U_1$  and  $U_2$  are related by the four process transfer functions  $G_{p11}$ ,  $G_{p12}$ , and so on. For example,  $G_{p11}$  denotes the transfer function between  $U_1$  and  $Y_1$ :

$$\frac{Y_1(s)}{U_1(s)} = G_{p11}(s) \quad (8-49)$$

Figure 8-40 includes two conventional feedback controllers:  $G_{c1}$  controls  $Y_1$  by manipulating  $U_1$ , and  $G_{c2}$  controls  $Y_2$  by manipulating  $U_2$ . The output signals from the feedback controllers serve as input signals to the two decouplers  $T_{12}$  and  $T_{21}$ . The block diagram is in a simplified form because the disturbance variables and transfer functions for the final control elements and sensors have been omitted.

The function of the decouplers is to compensate for the undesirable process interactions represented by  $G_{p12}$  and  $G_{p21}$ . Suppose that the process transfer functions are all known. Then the ideal design equations are

$$T_{12}(s) = -\frac{G_{p12}(s)}{G_{p11}(s)} \quad (8-50)$$

$$T_{21}(s) = -\frac{G_{p21}(s)}{G_{p22}(s)} \quad (8-51)$$

These decoupler design equations are very similar to the ones for feedforward control in an earlier section. In fact, decoupling can be interpreted as a type of feedforward control where the input signal is the output of a feedback controller rather than a measured disturbance variable.

In principle, ideal decoupling eliminates control loop interactions and allows the closed-loop system to behave as a set of independent control loops. But in practice, this ideal behavior is not attained for a variety of reasons, including imperfect process models and the presence of saturation constraints on controller outputs and manipulated variables. Furthermore, the ideal decoupler design equations in (8-50) and (8-51) may not be physically realizable and thus would have to be approximated.

In practice, other types of decouplers and decoupling control configurations have been employed. For example, in partial decoupling, only a single decoupler is employed (i.e., either  $T_{12}$  or  $T_{21}$  in Fig. 8-40

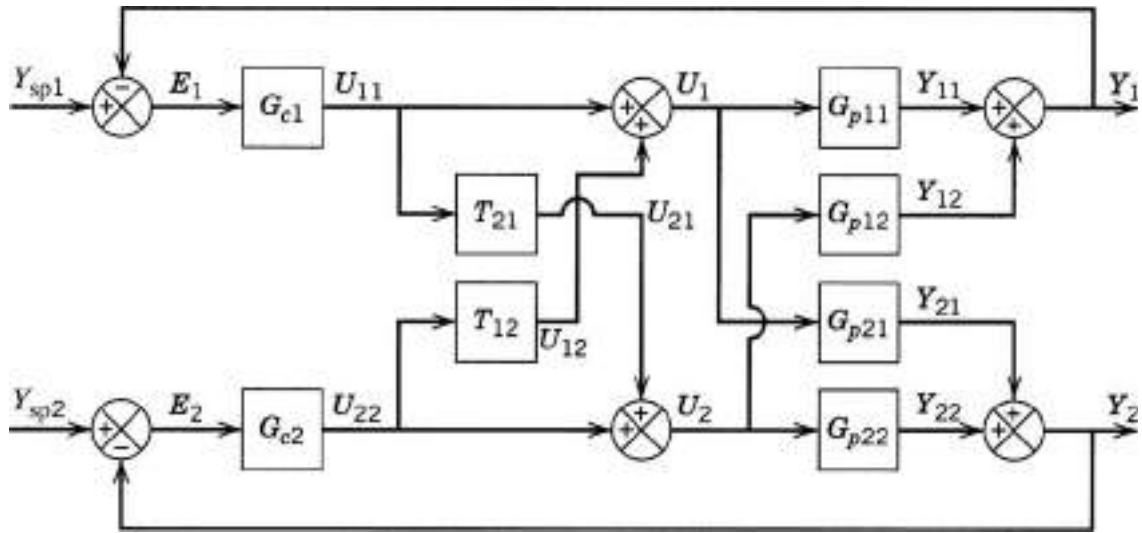

FIG. 8-40 A decoupling control system.

is set equal to zero). This approach tends to be more robust than complete decoupling and is preferred when one of the controlled variables is more important than the other. Static decouplers can be used to reduce the steady-state interactions between control loops. They can be designed by replacing the transfer functions in Eqs. (8-50) and (8-51) with the corresponding steady-state gains

$$T_{12}(s) = -\frac{K_{p12}}{K_{p11}} \quad (8-52)$$

$$T_{21}(s) = -\frac{K_{p21}}{K_{p22}} \quad (8-53)$$

The advantage of static decoupling is that less process information is required, namely, only steady-state gains. Nonlinear decouplers can be used when the process behavior is nonlinear.

**Pairing of Controlled and Manipulated Variables** A key decision in multiloop control system design is the pairing of manipulated and controlled variables. This is referred to as the controller pairing problem. Suppose there are  $N$  controlled variables and  $N$  manipulated variables. Then  $N!$  distinct control configurations exist. For example, if  $N = 5$ , then there are 120 different multiloop control schemes. In practice, many would be rejected based on physical insight or previous experience. But a smaller number (say, 5 to 15) may appear to be feasible, and further analysis would be warranted. Thus, it is very useful to have a simple method for choosing the most promising control configuration.

The most popular and widely used technique for determining the best controller pairing is the relative gain array (RGA) method (Bristol, "On a New Measure of Process Interaction," *IEEE Trans. Auto. Control*, AC-11: 133, 1966). The RGA method provides two important items of information:

1. A measure of the degree of process interactions between the manipulated and controlled variables
2. A recommended controller pairing

An important advantage of the RGA method is that it requires minimal process information, namely, steady-state gains. Another advantage is that the results are independent of both the physical units used and the scaling of the process variables. The chief disadvantage of the RGA method is that it neglects process dynamics, which can be an important factor in the pairing decision. Thus, the RGA analysis

should be supplemented with an evaluation of process dynamics. Although extensions of the RGA method that incorporate process dynamics have been reported, these extensions have not been widely applied.

**RGA Method for 2 × 2 Control Problems** To illustrate the use of the RGA method, consider a control problem with two inputs and two outputs. The more general case of  $N \times N$  control problems is considered elsewhere (McAvoy, *Interaction Analysis*, ISA, Research Triangle Park, N.C., 1983). As a starting point, it is assumed that a linear, steady-state process model in Eqs. (8-54) and (8-55) is available, where  $U_1$  and  $U_2$  are steady-state values of the manipulated inputs;  $Y_1$  and  $Y_2$  are steady-state values of the controlled outputs; and the  $K$  values are steady-state gains. The  $Y$  and  $U$  variables are deviation variables from nominal steady-state values. This process model could be obtained in a variety of ways, such as by linearizing a theoretical model or by calculating steady-state gains from experimental data or a steady-state simulation.

$$Y_1 = K_{11}U_1 + K_{12}U_2 \quad (8-54)$$

$$Y_2 = K_{21}U_1 + K_{22}U_2 \quad (8-55)$$

By definition, the relative gain  $\lambda_{ij}$  between the  $i$ th manipulated variable and the  $j$ th controlled variable is defined as

$$\lambda_{ij} = \frac{\text{open-loop gain between } Y_i \text{ and } U_j}{\text{closed-loop gain between } Y_i \text{ and } U_j} \quad (8-56)$$

where the open-loop gain is simply  $K_{ij}$  from Eqs. (8-54) and (8-55). The closed-loop gain is defined to be the steady-state gain between  $U_j$  and  $Y_i$  when the other control loop is closed and no offset occurs in the other controlled variable due to the presence of integral control action. The RGA for the  $2 \times 2$  process is denoted by

$$\Lambda = \begin{bmatrix} \lambda_{11} & \lambda_{12} \\ \lambda_{21} & \lambda_{22} \end{bmatrix} \quad (8-57)$$

The RGA has the important normalization property that the sum of the elements in each row and each column is exactly 1. Consequently, the RGA in Eq. (8-57) can be written as

$$\Lambda = \begin{bmatrix} \lambda & 1 - \lambda \\ 1 - \lambda & \lambda \end{bmatrix} \quad (8-58)$$

where  $\lambda$  can be calculated from the following formula:

$$\lambda = \frac{1}{1 - K_{12}K_{21}/(K_{11}K_{22})} \quad (8-59)$$
