The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Jacobsen, R. T., Penoncello, S. G., and Lemmon, E. W., "A Fundamental Equation for Trichlorofluoromethane (R-11)," *Fluid Phase Equilibria* **80**:45–56, 1992. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainties of the equation of state are 0.1% in density for the liquid, and 0.25% for the vapor, 2% in heat capacity, and 1% in the speed of sound, except in the critical region. The uncertainty in vapor pressure is 0.2%.

**FIG. 2-18** Pressure-enthalpy diagram for Refrigerant 11. Properties computed with the NIST REFPROP Database, Version 7.0 (Lemmon, E. W., McLinden, M. O., and Huber, M. L., 2002, NIST Standard Reference Database 23, NIST Reference Fluid Thermodynamic and Transport Properties—REFPROP, Version 7.0, Standard Reference Data Program, National Institute of Standards and Technology), based on the equation of state of Jacobsen, R. T., Penoncello, S. G., and Lemmon, E. W., "A Fundamental Equation for Trichlorofluoromethane (R-11)," *Fluid Phase Equilibria* **80**:45–56, 1992.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Marx, V., Pruss, A., and Wagner, W., "Neue Zustandsgleichungen fuer R 12, R 22, R 11 und R 113. Beschreibung des thermodynamischen Zustandsverhaltens bei Temperaturen bis 525 K und Druecken bis 200 MPa," Duesseldorf: *VDI Verlag*, Series 19 (Waermetechnik/Kaelte-technik), No. 57, 1992. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainties in density are 0.2% below the critical point temperature and increase to 1% in and above the critical region. The uncertainties for vapor pressures are 0.2% above 200 K and greater than 1% below 200 K. The uncertainties in heat capacities and sound speeds are 1% each.

**FIG. 2-19** Pressure-enthalpy diagram for Refrigerant 12. Properties computed with the NIST REFPROP Database, Version 7.0 (Lemmon, E. W., McLinden, M. O., and Huber, M. L., 2002, NIST Standard Reference Database 23, NIST Reference Fluid Thermodynamic and Transport Properties—REFPROP, Version 7.0, Standard Reference Data Program, National Institute of Standards and Technology), based on the equation of state of Marx, V., Prüß, A., and Wagner, W., "Neue Zustandsgleichungen für R 12, R 22, R 11 und R 113. Beschreibung des thermodynamischen Zustandsverhaltens bei Temperaturen bis 525 K und Drücken bis 200 MPa," VDI-Fortschritt-Ber. Series 19, No. 57, Düsseldorf: VDI Verlag, 1992.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Magee, J. W., Outcalt, S. L., and Ely, J. F., "Molar Heat Capacity  $C(v)$ , Vapor Pressure, and  $(p, \rho, T)$  Measurements from 92 to 350 K at Pressures to 35 MPa and a New Equation of State for Chlorotrifluoromethane (R13)," *Int. J. Thermophys.* **21**(5):1097–1121, 2000. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainties of the equation of state are 0.15% in density and 2% in heat capacity, except in the critical region. The uncertainty in vapor pressure is 0.1%.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Kamei, A., Beyerlein, S. W., and Jacobsen, R. T., "Application of Nonlinear Regression in the Development of a Wide Range Formulation for HCFC-22," *Int. J. Thermophys.* **16**:1155–1164, 1995. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainties of the equation of state are 0.1% in density, 1% in heat capacity, and 0.3% in the speed of sound, except in the critical region. The uncertainty in vapor pressure is 0.2%.

**FIG. 2-20** Pressure-enthalpy diagram for Refrigerant 22. Properties computed with the NIST REFPROP Database, Version 7.0 (Lemmon, E. W., McLinden, M. O., and Huber, M. L., 2002, NIST Standard Reference Database 23, NIST Reference Fluid Thermodynamic and Transport Properties—REFPROP, Version 7.0, Standard Reference Data Program, National Institute of Standards and Technology), based on the equation of state of Kamei, A., Beylerlein, S. W., and Jacobsen, R. T., "Application of Nonlinear Regression in the Development of a Wide Range Formulation for HCFC-22," *Int. J. Thermophysics* **16**:1155–1164, 1995.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Penoncello, S. G., Lemmon, E. W., Jacobsen, R. T., and Shan, Z., "A Fundamental Equation for Trifluoromethane (R-23)," *J. Phys. Chem. Ref. Data*, **32**(4):1473-1499, 2003. The source for viscosity and thermal conductivity is Shan, Z., Penoncello, S. G., and Jacobsen, R. T., "A Generalized Model for Viscosity and Thermal Conductivity of Trifluoromethane (R-23)," *ASHRAE Trans.* **106**:1-11, 2000.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainties of the equation of state are 0.1% in density, 0.5% in heat capacities and speed of sound, and 0.2% in vapor pressures. Uncertainties in the critical region will be higher. The uncertainty in viscosity is 1%. The uncertainty in thermal conductivity is 2%.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Tillner-Roth, R., and Yokozeki, A., "An International Standard Equation of State for Difluoromethane (R-32) for Temperatures from the Triple Point at 136.34 K to 435 K and Pressures up to 70 MPa," *J. Phys. Chem. Ref. Data* **26**(6):1273–1328, 1997. Validated equations for the viscosity are not currently available for this fluid. The source for thermal conductivity is unpublished; however, the fit uses the functional form found in Marsh, K., Perkins, R., and Ramires, M. L. V., "Measurement and Correlation of the Thermal Conductivity of Propane from 86 to 600 K at Pressures to 70 MPa," *J. Chem. Eng. Data* **47**(4):932–940, 2002.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

For the equation of state, typical uncertainties are 0.05% for density, 0.02% for the vapor pressure, and 0.5% to 1% for the heat capacity and speed of sound in the liquid phase. In the vapor phase, the uncertainty in the speed of sound is 0.02%. For thermal conductivity, the estimated uncertainty of the correlation is 5%, except for the dilute gas and points approaching critical where the uncertainty rises to 10%.

**FIG. 2-21** Pressure-enthalpy diagram for Refrigerant 32. Properties computed with the NIST REFPROP Database, Version 7.0 (Lemmon, E. W., McLinden, M. O., and Huber, M. L., 2002, NIST Standard Reference Database 23, NIST Reference Fluid Thermodynamic and Transport Properties—REFPROP, Version 7.0, Standard Reference Data Program, National Institute of Standards and Technology), based on the equation of state of Tillner-Roth, R., and Yokozeki, A., "An International Standard Equation of State for Difluoromethane (R-32) for Temperatures from the Triple Point at 136.34 K to 435 K and Pressures up to 70 MPa," *J. Phys. Chem. Ref. Data* **26**(6):1273-1328, 1997.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Lemmon, E. W., and Span, R., "Short Fundamental Equations of State for 20 Industrial Fluids," *J. Chem. Eng. Data*, **51**(3):785–850, 2006. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainties in the equation of state are 0.1% in density (except near the critical point), 0.25% in vapor-pressure, 1% in heat capacities, 0.2% in the vapor-phase speed of sound, and 3% in the liquid speed of sound. The liquid speed of sound uncertainty is an estimate and cannot be verified without experimental information. The uncertainties above 290 K in vapor pressure may be as high as 0.5%.

## 2-350 PHYSICAL AND CHEMICAL DATA

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Marx, V., Pruss, A., and Wagner, W., "Neue Zustandsgleichungen fuer R 12, R 22, R 11 und R 113. Beschreibung des thermodynamischen Zustandsverhaltens bei Temperaturen bis 525 K und Druecken bis 200 MPa," Duesseldorf: *VDI Verlag*, Series 19 (Waermetechneik/Kaeltetechnik), No. 57, 1992. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainty in density is 0.2%, that for vapor pressure is 0.3%, and that for the isobaric heat capacity is 2%. The uncertainties are higher in and above the critical region.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Platzer, B., Polt, A., and Maurer, G., *Thermophysical Properties of Refrigerants*, Springer-Verlag, Berlin, 1990. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the critical point temperature are given in the last entry of the saturation tables. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainty in density is 0.2% up to 400 K and 1% at higher temperatures. The vapor pressure uncertainty is 1.5%. In the liquid phase, the uncertainty in isobaric heat capacity is 3%.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Lemmon, E. W., and Span, R., "Short Fundamental Equations of State for 20 Industrial Fluids," *J. Chem. Eng. Data* **51**(3):785–850, 2006. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainties in the equation are 0.5% in density for liquid and vapor states and 1% in density or pressure for supercritical states. For vapor pressure, the uncertainty is 0.3%, that for vapor-phase speed of sounds is 0.2%, and the uncertainty for heat capacities is 5%.

**TABLE 2-275 Thermodynamic Properties of R-123, 2,2-Dichloro-1,1,1-Trifluoroethane**

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Younglove, B. A., and McLinden, M. O., "An International Standard Equation of State for the Thermodynamic Properties of Refrigerant 123 (2,2-Dichloro-1,1,1-Trifluoroethane)," *J. Phys. Chem. Ref. Data* **23**:731–779, 1994. The source for viscosity is Tanaka, Y. and Sotani, T., "Transport Properties (Thermal Conductivity and Viscosity)," in McLinden, M. O., Ed., *R123—Thermodynamic and Physical Properties*, Paris: International Institute of Refrigeration, 1995. See also *Int. J. Thermophys.* **17**(2):293–328, 1996. The source for thermal conductivity is Laesecke, A., Perkins, R. A., and Howley, J. B., "An Improved Correlation for the Thermal Conductivity of HCFC123 (2,2-Dichloro-1,1,1-Trifluoroethane)," *Int. J. Refrigeration* **19**:231–238, 1996.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainties of the equation of state are 0.1% in density, 1.5% in heat capacity, and 2% in the speed of sound, except in the critical region. The uncertainty in vapor pressure is 0.1%. Uncertainties are greater below 180 K. The uncertainty in viscosity is 5%. The uncertainty in thermal conductivity is 2%.

FIG. 2-24 Enthalpy-log-pressure diagram for Refrigerant 123.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is de Vries, B., Tillner-Roth, R., and Baehr, H. D., "Thermodynamic Properties of HCFC 124," *19th Int. Congress of Refrigeration*, The Hague, The Netherlands, International Institute of Refrigeration, IVa:582–589, 1995. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainties of the equation of state are 0.05% in density, 1% in heat capacity, and 1% in the speed of sound, except in the critical region. The uncertainty in vapor pressure is 0.1%.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Lemmon, E. W., and Jacobsen, R. T., "A New Functional Form and New Fitting Techniques for Equations of State with Application to Pentafluoroethane (HFC-125)," *J. Phys. Chem. Ref. Data* **34**(1):69–108, 2005. The source for viscosity is Huber, M. L., and Laesecke, A., "Correlation for the Viscosity of Pentafluoroethane (R125) from the Triple Point to 500 K at Pressures up to 60 MPa," *Ind. Eng. Chem. Res.*, **45**(12):4447–4453, 2006. The source for thermal conductivity is Perkins, R., and Huber, M. L., "Measurement and Correlation of the Thermal Conductivity of Pentafluoroethane (R125) from 190 K to 512 K at Pressures to 70 MPa," *J. Chem. Eng. Data* **51**(3):898–904, 2006.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainty in density is 0.1% at temperatures from the triple point to 400 K at pressures up to 60 MPa, except in the critical region, where an uncertainty of 0.2% in pressure is generally attained. In the limited region between 340 and 400 K and at pressures from 4 to 10 MPa, as well as for all states above 400 K, the uncertainty in density increases to 0.5%. At temperatures below 330 K and pressures below 30 MPa, the uncertainty in density in the liquid phase may be as low as 0.04%. In the vapor and supercritical region, speed of sound data are represented within 0.05% at pressures below 1 MPa. The estimated uncertainty for heat capacities is 0.5%, and the estimated uncertainty for the speed of sound in the liquid phase is 0.5% for  $T > 250$  K. The estimated uncertainties of vapor pressures and saturated liquid densities calculated using the Maxwell criterion are 0.1% for each property, and the estimated uncertainty for saturated vapor densities is 0.2%. The uncertainty in density increases as the critical point is approached, while the accompanying uncertainty in calculated pressures is 0.2%. The viscosity correlation has an estimated uncertainty of 3.0% along the saturation boundary in the liquid phase, and 0.8% in the vapor. For thermal conductivity, the estimated uncertainty of the correlation is 3%, except for the dilute gas and points approaching critical, where the uncertainty rises to 5%.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Tillner-Roth, R., and Baehr, H. D., "An International Standard Formulation of the Thermodynamic Properties of 1,1,1,2-Tetrafluoroethane (HFC-134a) for temperatures from 170 K to 455 K at Pressures up to 70 MPa," *J. Phys. Chem. Ref. Data* **23**:657–729, 1994. The source for viscosity is Huber, M. L., Laesecke, A., and Perkins, R. A., "Model for the Viscosity and Thermal Conductivity of Refrigerants, Including a New Correlation for the Viscosity of R134a," *Ind. Eng. Chem. Res.* **42**:3163–3178, 2003. The source for thermal conductivity is Perkins, R. A., Laesecke, A., Howley, J., Ramirez, M. L. V., Gurova, A. N., and Cusco, L., "Experimental Thermal Conductivity Values for the IUPAC Round-Robin Sample of 1,1,1,2-Tetrafluoroethane (R134a)," NISTIR, 2000.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

Typical uncertainties are 0.05% for density, 0.02% for vapor pressure, 0.5% to 1% for heat capacity, 0.05% for vapor speed of sound, and 1% for liquid speed of sound, except in the critical region. The uncertainty in viscosity is 1.5% along the saturated-liquid line, 3% in the liquid phase, 0.5% in the dilute gas, 3% to 5% in the vapor phase, and 5% in the supercritical region, rising to 8% at pressures above 40 MPa. Below 200 K, the uncertainty is 8%. The uncertainty in thermal conductivity is 5%.

**FIG. 2-26** Pressure-enthalpy diagram for Refrigerant 134a. Properties computed with the NIST REFPROP Database, Version 7.0 (Lemmon, E. W., McLinden, M. O., and Huber, M. L., 2002, NIST Standard Reference Database 23, NIST Reference Fluid Thermodynamic and Transport Properties—REFPROP, Version 7.0, Standard Reference Data Program, National Institute of Standards and Technology), based on the equation of state of Tillner-Roth, R., and Baehr, H. D., "An International Standard Formulation of the Thermodynamic Properties of 1,1,1,2-Tetrafluoroethane (HFC-134a) Covering Temperatures from 170 K to 455 K at Pressures up to 70 MPa," *J. Phys. Chem. Ref. Data* **23**(5):657–729, 1994.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Lemmon, E. W., and Span, R., "Short Fundamental Equations of State for 20 Industrial Fluids," *J. Chem. Eng. Data* **51**(3):785–850, 2006. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The equation has uncertainties of 0.2% in density between 180 and 400 K at pressures to 100 MPa, and 0.5% in density at higher pressures. The uncertainty in density may be higher as temperatures approach 400 K. Vapor pressures are represented with an uncertainty of 0.2% from 270 to 400 K. The uncertainty in speed of sound is 0.01% in the vapor phase and 0.5% in the liquid phase. There are no heat capacity data to verify the equation of state; however, the uncertainties are estimated to be within 2%.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Lemmon, E. W., and Span, R., "Short Fundamental Equations of State for 20 Industrial Fluids," *J. Chem. Eng. Data* **51**(3):785–850, 2006. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainties in density are 0.3% in the liquid phase below 370 K, 1% at higher temperatures in the liquid and supercritical regions, and 0.5% in the vapor phase. Uncertainties for other properties are 0.5% for vapor pressure, 2% for heat capacities and liquid sound speeds, and 0.2% for vapor sound speeds.

**TABLE 2-281 Thermodynamic Properties of R-143a, 1,1,1-Trifluoroethane**

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Lemmon, E. W., and Jacobsen, R. T., "An International Standard Formulation for the Thermodynamic Properties of 1,1,1-Trifluoroethane (HFC-143a) for Temperatures from 161 to 450 K and Pressures to 50 MPa," *J. Phys. Chem. Ref. Data* **29**(4):521–552, 2000. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The estimated uncertainties of properties calculated using the equation of state are 0.1% in density, 0.5% in heat capacities, 0.02% in the speed of sound for the vapor at pressures less than 1 MPa, 0.5% in speed of sound elsewhere, and 0.1% in vapor pressure, except in the critical region.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Outcalt, S. L., and McLinden, M. O., "A Modified Benedict-Webb-Rubin Equation of State for the Thermodynamic Properties of R152a (1,1-Difluoroethane)," *J. Phys. Chem. Ref. Data* **25**(2):605-636, 1996. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainties of the equation of state are 0.1% in density, 2% in heat capacity, and 0.05% in the vapor speed of sound, except in the critical region. The uncertainty in vapor pressure is 0.1%.

<sup>c</sup>From published data, Chemicals Division, Union Carbide Corporation. Used by permission. The paper describing these data is by Shank, *ASHRAE J.*, **1**(1965): 94-101. *c* = critical temperature.

The 1993 ASHRAE *Handbook—Fundamentals* (SI ed.) gives material for integral degrees Celsius with temperatures on the ITS 90 scale from -118.59 to 113.26 °C. The thermodynamic diagram from 0.1 to 30 bar extends to 180 °C. For tables and a diagram to 400 psia, 360 °F, see Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants*, ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat and viscosity, see *Thermophysical Properties of Refrigerants*, ASHRAE, 1993. Thermal conductivity data as a function of pressure and temperature are reported by Krauss, R. and K. Stephan, *Proc. 12th Symp. Thermophys. Props.*, Boulder, CO, 1994.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Lemmon, E. W., and Span, R., "Short Fundamental Equations of State for 20 Industrial Fluids," *J. Chem. Eng. Data* **51**(3):785–850, 2006. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainty in density is 0.2% for the liquid phase and 0.5% for the vapor phase. Above the critical temperature, the uncertainties are estimated to be 1% in density and 0.5% in pressure. Calculated vapor pressures have an uncertainty of 0.5%. The uncertainties for heat capacities and sound speeds are 1%.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is an interim equation from Lemmon, E. W., personal communication (NIST, Boulder, CO, 2006). Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainties in the equation of state are 0.2% in density, except in a small region close to the critical point, 0.2% in vapor pressure between 250 and 360 K, 0.4% in vapor pressure outside this region, 1% in heat capacities (with increasing uncertainties in the critical region and at higher temperatures), 0.1% in the vapor-phase speed of sound, and 3% in the liquid-phase speed of sound.

TABLE 2-286 Saturated Refrigerant 245cb 1,1,1,2,2-Pentafluoropropane\*

\*Values of  $P$ ,  $v$ ,  $h$ , and  $s$  interpolated, extrapolated, and converted from tables of Oguchi, *Reito*, **52** (1977): 869-889. Values of  $c_p$ ,  $\mu$ , and  $k$  interpolated and converted from tables in *Thermophysical Properties of Refrigerants*, American Society of Heating, Refrigerating and Air-Conditioning Engineers, New York, 1976.  $c$  = critical point. Saturation and superheat tables and a diagram to 80 bar, 580 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.*, Stanford Univ. publ., 1979 (173 pp.). For equations, see Cipollone, R., *ASHRAE Trans.*, **97**, 2 (1991): 262-267.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Lemmon, E. W., "Pseudo Pure-Fluid Equations of State for the Refrigerant Blends R-410A, R-404A, R-507A, and R-407C," *Int. J. Thermophys.* **24**(4):991–1006, 2003. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the critical point temperature are given in the last entry of the saturation tables. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The estimated uncertainty of density values calculated with the equation of state is 0.1%. The estimated uncertainty of calculated heat capacities and speed of sound values is 0.5%. Uncertainties of bubble and dew point pressures are 0.5%.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Lemmon, E. W., "Pseudo Pure-Fluid Equations of State for the Refrigerant Blends R-410A, R-404A, R-507A, and R-407C," *Int. J. Thermophys.* **24**(4):991–1006, 2003. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the critical point temperature are given in the last entry of the saturation tables. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The estimated uncertainty of density values calculated with the equation of state is 0.1%. The estimated uncertainty of calculated heat capacities and speed of sound values is 0.5%. Uncertainties of bubble and dew point pressures are 0.5%.

**FIG. 2-27** Pressure-enthalpy diagram for Refrigerant 407C. Properties computed with the NIST REFPROP Database, Version 7.0 (Lemmon, E. W., McLinden, M. O., and Huber, M. L., 2002, NIST Standard Reference Database 23, NIST Reference Fluid Thermodynamic and Transport Properties—REFPROP, Version 7.0, Standard Reference Data Program, National Institute of Standards and Technology), based on the mixture model of Lemmon, E. W., and Jacobsen, R. T., "Equations of State for Mixtures of R-32, R-125, R-134a, R-143a, and R-152a," *J. Phys. Chem. Ref. Data* **33**:593–620, 2004.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Lemmon, E. W., "Pseudo Pure-Fluid Equations of State for the Refrigerant Blends R-410A, R-404A, R-507A, and R-407C," *Int. J. Thermophys.* **24**(4):991–1006, 2003. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the critical point temperature are given in the last entry of the saturation tables. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The estimated uncertainty of density values calculated with the equation of state is 0.1%. The estimated uncertainty of calculated heat capacities and speed of sound values is 0.5%. Uncertainties of bubble and dew point pressures are 0.5%.

TABLE 2-291 Saturated Refrigerant 500\*

| T, K               | P, bar | $v_f, m^3/kg$ | $v_g, m^3/kg$ | $h_f, kJ/kg$ | $h_g, kJ/kg$ | $s_f, kJ/(kg \cdot K)$ | $s_g, kJ/(kg \cdot K)$ | $c_{pf}, kJ/(kg \cdot K)$ | $\mu_f, 10^{-4} Pa \cdot s$ | $k_f, W/(m \cdot K)$ |

The 1993 *ASHRAE Handbook—Fundamentals* (SI ed.) gives material for integral degrees Celsius with temperatures on the IPTS 68 scale from -70 to 105.60 °C. The thermodynamic diagram from 0.1 to 70 bar extends to 240 °C. Equations and constants approximated to the 1985 ASHRAE tables were given by Meczaryk, K. and M. Masaryk, *Heat Recovery Systems and CHP*, 11, 2/3 (1991): 193-197. Saturation and superheat tables and a diagram to 80 bar, 560 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.*, Stanford Univ. publ., 1979 (173 pp.). Tables and a chart to 1000 psia, 480 °F are given by Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants*, ASHRAE, Atlanta, GA, 1986 (521 pp.). Specific heat and viscosity appear in *Thermophysical Properties of Refrigerants*, ASHRAE, 1993.

The 1993 *ASHRAE Handbook—Fundamentals* (SI ed.) gives material for integral degrees Celsius with temperatures on the IPTS 68 scale from -70 to 82.2 °C. The thermodynamic diagram from 0.1 to 80 bar extends to 180 °C. Equations and constants approximated to 1985 ASHRAE tables are given by Meczaryk, K., and M. Masaryk, *Heat Recovery Systems and CHP*, 11, 2/3 (1991): 193-197. Saturation and superheat tables and a diagram to 20 bar, 515 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.*, Stanford Univ. publ., 1979 (173 pp.). Tables and a chart to 1000 psia, 400 °F appear in Stewart, R. B., R. T. Jacobsen, et al., *Thermodynamic Properties of Refrigerants*, ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat and viscosity, see *Thermophysical Properties of Refrigerants*, ASHRAE, 1993.

\*P, v, h, and s values reproduced and converted from Table 14, p. 17.103, ASHRAE Handbook, 1981: Fundamentals, American Society of Heating, Refrigerating and Air-Conditioning Engineers, Atlanta, 1981. Copyright material. Reproduced by permission of the copyright owner.  $c_p$ ,  $\mu$ , and  $k$  values interpolated and converted from Thermophysical Properties of Refrigerants, American Society of Heating, Refrigerating and Air-Conditioning Engineers, New York, 1976.  $c$  = critical point. The notation 6.384-4 signifies  $6.384 \times 10^{-4}$ .

Saturation and superheat tables and a diagram to 80 bar, 600 K are given by Reynolds, W. C., Thermodynamic Properties in S.I., Stanford Univ. publ., 1979 (173 pp.). Tables and a chart to 1000 psia, 460 °F are given by Stewart, R. B., R. T. Jacobsen, et al., Thermodynamic Properties of Refrigerants, ASHRAE, Atlanta, GA, 1986 (521 pp.). For specific heat and viscosity see Thermophysical Properties of Refrigerants, ASHRAE, 1993. The 1993 ASHRAE Handbook—Fundamentals (SI ed.) gives material for integral degrees Celsius with temperatures on the IPTS 68 scale for saturation conditions from -125 to 19.50 °C. The thermodynamic diagram from 0.1 to 80 bar extends to 220 °C.

\*Azeotropic mixture of R152a and R218.  $h_f = s_f = 0$  at 233.15 K = -40 °C. Interpolated, extrapolated and converted from Lavrenchenko, G. K., M. G. Khmelnuik, et al., Int. J. Refrig., 17, 7 (1994): 461. Some values are tentative. This source also gives a ln P-h diagram from 0.6 to 30 bar, -50 to 70 °C. Differences exist between the published diagram and tables.  $c$  = critical point.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Lemmon, E. W., "Pseudo Pure-Fluid Equations of State for the Refrigerant Blends R-410A, R-404A, R-507A, and R-407C," *Int. J. Thermophys.* **24**(4):991–1006, 2003. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the critical point temperature are given in the last entry of the saturation tables. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The estimated uncertainty of density values calculated with the equation of state is 0.1%. The estimated uncertainty of calculated heat capacities and speed of sound values is 0.5%. Uncertainties of bubble and dew point pressures are 0.5%.

TABLE 2-297 Saturated Rubidium\*

\*Converted from tables in Vargaftik, *Tables of the Thermophysical Properties of Liquids and Gases*, Nauka, Moscow, 1972, and Hemisphere, Washington, 1975.  $m$  = melting point. The notation 2.46.-9 signifies  $2.46 \times 10^{-9}$ .

Many of the Vargaftik values also appear in Ohse, R. W., *Handbook of Thermodynamic and Transport Properties of Alkali Metals*, Blackwell Sci. Pubs., Oxford, 1985 (1020 pp.). This source contains superheat data.

Saturation and superheat tables and a diagram to 40 bar, 1600 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.*, Stanford Univ. publ., 1979 (173 pp.).

For a Mollier diagram from 0.1 to 320 psia, 1200 to 2700 °R, see Weatherford, W. D., J. C. Tyler, et al., WADD-TR-61-96, 1961. An extensive review of properties of the solid and the saturated liquid was given by Alcock, C. B., M. W. Chase, et al., *J. Phys. Chem. Ref. Data*, **23**, 3 (1994): 385-497.

$\kappa = (-1/V)(\partial v/\partial p)_T \cdot 10^5$ . Thus, at 0 °C, the compressibility is  $5.06 \times 10^{-5}$ /bar.

For further information see, for instance, Bromley, LeR. A., *J. Chem. Eng. Data*, **12**, 2 (1967): 202-206; **13**, 1 (1968): 60-62 and **13**, 3: 399-402; **15**, 2 (1970): 246-253; and *A.I.Ch.E.J.*, **20**, 2 (1974): 326-335.

<sup>c</sup> = critical point.

$s_f$  values converted from Cordfunke, E. H. P. and R. J. M. Konings, *Thermochemical Data for Reactor Materials and Fission Products*, North Holland Elsevier, NY, 1990.  $s_g$  determined as  $s_f + (h_g - h_f)/T$ .  $\mu_g$  and  $k_g$  values estimated by P. E. Liley. All other values are from Fink, J. K. and L. Leibowitz, Argonne Nat. Lab Rept. ANL/RE-95-2, 1995. The Fink and Leibowitz work also appeared in *High Temp. Materials Sci.*, **35**, 65-103, 1996. Saturation and superheat tables and a diagram to 14 bar; 1700 K are given by Reynolds, W. C., *Thermodynamic Properties in S.I.*, Stanford Univ. publ., 1979 (173 pp.). For a Mollier diagram for 0.1-150 psia, 1500-2700 °R, see Weatherford, P. M., J. C. Tyler, et al., WADD-TR-61-96, 1961.

**FIG. 2-28** Mollier Diagram for Sodium. Drawn from the Vargaftik et al. values in Ohse, R. W., *Handbook of Thermodynamic and Transport Properties of Alkali Metals*, Blackwell Sci. Pubs., Oxford, UK, 1985. These values are identical with those of Vargaftik, N. B., *Handbook of Thermophysical Properties of Gases and Liquids*, Moscow, 1972, and the Hemisphere translation, p. 19. An apparent discontinuity exists between the superheat values and the saturation values, not reproduced here. For a Mollier diagram in f.p.s. units from 0.1 to 150 psia, 1500 to 2700°R, see Fig. 3-36, p. 3-232 of the 6th edition of this handbook. An extensive review of properties of the solid and the saturated liquid was given by Alcock, C. B., Chase, M. W. et al., *J. Phys. Chem. Ref. Data*, **23**(3), 385-497, 1994.

**FIG. 2-29** Enthalpy-concentration diagram for aqueous sodium hydroxide at 1 atm. Reference states: enthalpy of liquid water at 32 °F and vapor pressure is zero; partial molal enthalpy of infinitely dilute NaOH solution at 64 °F and 1 atm is zero. [McCabe, *Trans. Am. Inst. Chem. Eng.*, 31, 129 (1935).]

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Lemmon, E. W., and Span, R., *J. Chem. Eng. Data*, **51**(3):785–850, 2006. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainty in density of the equation of state ranges from 0.1% at low temperatures in the liquid and vapor to 0.5% at the highest temperatures. The uncertainty in heat capacities is 2%, and the uncertainty in vapor pressure is 0.4% at temperatures above 270 K. The uncertainty in vapor pressure increases at lower temperatures due to the lack of experimental data. In the critical region, the uncertainties are higher for all properties except vapor pressure.

**TABLE 2-301 Thermodynamic Properties of Sulfur Hexafluoride**

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is de Reuck, K. M., Craven, R. J. B., and Cole, W. A., "Report on the Development of an Equation of State for Sulphur Hexafluoride," *IUPAC Thermodynamic Tables Project Centre*, London, 1991. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainties of the equation of state are 0.1% in density, 2% in heat capacity, and 5% in the speed of sound, except in the critical region.

**FIG. 2-30** Pressure-enthalpy diagram for sulfur hexafluoride ( $\text{SF}_6$ ). Properties computed with the NIST REFPROP Database, Version 7.0 (Lemmon, E. W., McLinden, M. O., and Huber, M. L., 2002, NIST Standard Reference Database 23, NIST Reference Fluid Thermodynamic and Transport Properties—REFPROP, Version 7.0, Standard Reference Data Program, National Institute of Standards and Technology), based on the equation of state of de Reuck, K. M., Craven, R. J. B., and Cole, W. A., "Report on the Development of an Equation of State for Sulphur Hexafluoride," IUPAC Thermodynamic Tables Project Centre, London, 1991.

**FIG. 2-31** Enthalpy-concentration diagram for aqueous sulfuric acid at 1 atm. Reference states: enthalpies of pure-liquid components at 32° F and vapor pressures are zero. NOTE: It should be observed that the weight basis includes the vapor, which is particularly important in the two-phase region. The upper ends of the tie lines in this region are assumed to be pure water. (*Hougen and Watson, Chemical Process Principles, part I, Wiley, New York, 1943.*)

**TABLE 2-302 Saturated SUVA AC 9000**

DuPont bulletin T-AC-9000-SI, 1994 (16 pp.) gives tables and a chart to 100 bar, 235°C. With a stated composition of 23% wt CH<sub>2</sub>F<sub>2</sub> (R23), 25% wt CHF<sub>2</sub>CF<sub>3</sub> (R125), and 52% wt CH<sub>2</sub>FCH<sub>3</sub> (R134a) this is apparently identical to KLEA 66, to which the reader is referred.

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Lemmon, E. W., and Span, R., "Short Fundamental Equations of State for 20 Industrial Fluids," *J. Chem. Eng. Data* **51**(3):785–850, 2006. Validated equations for the viscosity and thermal conductivity are not currently available for this fluid.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainties in density in the equation of state are 0.05% in the liquid phase up to 540 K, 0.5% up to the critical temperature, 1% at higher temperatures, 0.5% at pressures from 100 to 500 MPa, and 0.2% in the vapor phase. The uncertainty for the saturated-liquid density (and densities near atmospheric pressure) approaches 0.01% around 300 K. The uncertainties in vapor pressure are 0.3% from 270 to 305 K, 0.05% from 305 to 425 K, 0.1% up to 555 K, and 0.15% up to the critical temperature. The uncertainty in heat capacities is 0.5% and rises to 3% in the critical region. The uncertainty in the speed of sound is 1% up to 500 K and 100 MPa and rises to 2% at higher pressures and higher temperatures.

TABLE 2-304 Saturated Solid/Vapor Water\*

| Temp.,<br>°F | Pressure,<br>lb/in <sup>2</sup> abs. | Volume,<br>ft <sup>3</sup> /lb |          | Enthalpy,<br>Btu/lb |         | Entropy,<br>Btu/(lb)(°F) |        |

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Wagner, W., and Pruss, A., "The IAPWS Formulation 1995 for the Thermodynamic Properties of Ordinary Water Substance for General and Scientific Use," *J. Phys. Chem. Ref. Data* 31(2):387–535, 2002. The source for viscosity is International Association for the Properties of Water and Steam, *Revised Release on the IAPS Formulation 1985 for the Viscosity of Ordinary Water Substance*, IAPWS, 1997. The source for thermal conductivity is the International Association for the Properties of Water and Steam, *Revised Release on the IAPS Formulation 1985 for the Thermal Conductivity of Ordinary Water Substance*, IAPWS, 1998.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainty in density of the equation of state is 0.0001% at 1 atm in the liquid phase, and 0.001% at other liquid states at pressures up to 10 MPa and temperatures to 423 K. In the vapor phase, the uncertainty is 0.05% or less. The uncertainties rise at higher temperatures and/or pressures, but are generally less than 0.1% in density except at extreme conditions. The uncertainty in pressure in the critical region is 0.1%. The uncertainty of the speed of sound is 0.15% in the vapor and 0.1% or less in the liquid, and increases near the critical region and at high temperatures and pressures. The uncertainty in isobaric heat capacity is 0.2% in the vapor and 0.1% in the liquid, with increasing values in the critical region and at high pressures. The uncertainties of saturation conditions are 0.025% in vapor pressure, 0.0025% in saturated-liquid density, and 0.1% in saturated-vapor density. The uncertainties in the saturated densities increase substantially as the critical region is approached. For the uncertainties in the viscosity and thermal conductivity, see the IAPWS Release.

Condensed from U. Grigull, Private communication, January 18, 1995.

Materials prepared at Technical University München, Germany by U. Grigull and S. Marek. For a table as a function of temperature, see Grigull, U. and S. Marek, *Wärme u. Stoff.*, **30** (1994): 1–8.

$t$  = the triple point (at  $6.117 \times 10^{-3}$  bar, 0.01 °C);  $v_f = 0.0010021$  m<sup>3</sup>/kg;  $\alpha_f = -67.42 \times 10^{-6}$ /K.

Other equations for properties are given by Jones, F. E. and G. L. Harris, *J. Res. N.I.S.T.*, **97**, 3 (1992): 335–340, and by Wagner, W. and A. Pruss, *J. Phys. Chem. Ref. Data*, **22**, 3 (1993): 783–787. Steam tables include Walker, W. A., U.S. Naval Ordn. Lab. rept. NOLTR NOLTR-66-217 = AD 651105 (0–1000 bar, 0–150°C), 1967 (72 pp.); Grigull, U., J. Straub, et al., *Steam Tables in S.I. Units* (0.01–1000 bar, 0–1000 °C), Springer-Verlag, Berlin, 1990 (133 pp.); Tseng, C. M., T. A. Hamp, et al., Atomic Energy of Canada rept. (30 props, sat liq & vap., 1–220 bar), AECL-5910 1977 (90 pp.). For dissociation, see e.g., Knonicek, V., *Rozpr. Cesko Acad Ved., Rada techn ved* (0.01–100 bar, 1000–5000 K), **77**, 1 (1967). The proceedings of the 10th international conference on the properties of steam were edited by Sytchev, V. V. and A. A. Aleksandrov, Plenum, NY, 1984; and for the 11th conference by Fichal, M. and O. Sifner, Hemisphere, 1989 (550 pp.). Current information on the properties of solid, vapor, and liquid water properties can be found at <http://www.iapws.org>.

For electrical conductivity, see e.g., Marshall, W. L., *J. Chem. Eng. Data*, **32** (1987): 221–226.

**TABLE 2-307 Thermodynamic Properties of Xenon**

The values in these tables were generated from the NIST REFPROP software (Lemmon, E. W., McLinden, M. O., and Huber, M. L., NIST Standard Reference Database 23: Reference Fluid Thermodynamic and Transport Properties—REFPROP, National Institute of Standards and Technology, Standard Reference Data Program, Gaithersburg, Md., 2002, Version 7.1). The primary source for the thermodynamic properties is Lemmon, E. W., and Span, R., "Short Fundamental Equations of State for 20 Industrial Fluids," *J. Chem. Eng. Data* **51**(3):785–850, 2006. The source for viscosity and thermal conductivity is McCarty, R. D., *Correlations for the Thermophysical Properties of Xenon*, National Institute of Standards and Technology, Boulder, Colo., 1989.

Properties at the triple point temperature and the critical point temperature are given in the first and last entries of the saturation tables, respectively. In the single-phase table, when the temperature range for a given isobar includes a vapor-liquid phase boundary, the temperature of phase equilibrium is noted, and properties for both the saturated liquid and saturated vapor are given (with liquid properties given in the upper line). Lines are omitted from the temperature-pressure grid of the single-phase table, when the system would be in the solid phase or if there are potential problems with the source property surface.

The uncertainties in the equation of state are 0.2% in density up to 100 MPa, rising to 1% at higher pressures, 0.2% in vapor pressure, 1% in the speed of sound, and 2% in heat capacities. For viscosity, estimated uncertainty is less than 5%. For thermal conductivity, estimated uncertainty is less than 6%.

TABLE 2-308 Surface Tension (N/m) of Saturated Liquid Refrigerants\*

| R no. | Temperature, °C |        |        |        |        |        |        |        |        |

## TRANSPORT PROPERTIES

### INTRODUCTION

Extensive tables of the viscosity and thermal conductivity of air and of water or steam for various pressures and temperatures are given with the thermodynamic-property tables. The thermal conductivity and the viscosity for the saturated-liquid state are also tabulated for many fluids along with the thermodynamic-property tables earlier in this section.

### UNITS CONVERSIONS

For this subsection the following units conversions are applicable:

Diffusivity: to convert square centimeters per second to square feet per hour, multiply by 3.8750; to convert square meters per second to square feet per hour, multiply by 38,750.

Pressure: to convert bars to pounds-force per square inch, multiply by 14.504.

Temperature: °F =  $\frac{9}{5}$  °C + 32; °R =  $\frac{9}{5}$  K.

Thermal conductivity: to convert watts per meter-kelvin to British thermal unit–feet per hour–square foot–degree Fahrenheit, multiply by 0.57779; and to convert British thermal unit–feet per hour–square foot–degree Fahrenheit to watts per meter-kelvin, multiply by 1.7307.

Viscosity: to convert pascal-seconds to centipoises, multiply by 1000.

### ADDITIONAL REFERENCES

An extensive coverage of the general pressure and temperature variation of thermal conductivity is given in the monograph by Vargaftik, Filippov, Tarzimanov, and Totksiy, *Thermal Conductivity of Liquids and Gases* (in Russian), Standartov, Moscow, 1978, now published in English translation by CRC Press, Miami, FL.

For a similar work on viscosity, see Stephan and Lucas, *Viscosity of Dense Fluids*, Plenum, New York and London, 1979. Tables and

polynomial fits for refrigerants in both the gaseous and the liquid state are contained in *ASHRAE Handbook—Fundamentals*, SI ed., ASHRAE, Atlanta, 2005. Other sources for viscosity include Fischer & Porter Co. catalog 10-A-94, "Fluid densities and viscosities," 1953 (200 industrial fluids in 48 pp.) and van Velzen, D., R. L. Cardozo et al., EURATOM Ispra, Italy rept. 4735 e, 1972 (160 pp.). Liquid viscosity, 314 cpds, is summarized in *I&EC Fundtls.*, 11 (1972): 20–26. Five hundred forty-nine binary and ternary systems are discussed in Skubla, P., *Coll. Czech. Chem. Commun.*, 46 (1981): 303–339.

See also Duhne, C. R., *Chem. Eng. (NY)*, 86, 15 (July 16, 1979): 83–91 (equations and 326 liquids); and Rao, K. V. K., *Chem. Eng. (NY)*, 90, 11 (May 30, 1983): 90–91 (nomograph, 87 liquids). For rheology, non-Newtonian behavior, and the like, see, for instance, Barnes, H., *The Chem. Engr. (UK)*, (June 24, 1993): 17–23; Hyman, W. A., *I&EC Fundtls.*, 16 (1976): 215–218; and Ferguson, J. and Z. Kemblowski, *Applied Fluid Rheology*, Elsevier, 1991 (325 pp.). Other sources for thermal conductivity include Ho, C. Y., R. W. Powell et al., *J. Phys. Chem. Ref. Data*, 1 (1972) and 3, suppl. 1 (1974); Childs, Ericks et al., N.B.S. Monogr. 131, 1973; Jamieson, D. T., J. B. Irving et al., *Liquid Thermal Conductivity*, H.M.S.O., Edinburgh, Scotland, 1975 (220 pp.).

The vapor viscosity is calculated by

$$\mu = \frac{C1T^{C2}}{1 + C3/T + C4/T^2}$$

where  $\mu$  is the viscosity in Pa-s and  $T$  is the temperature in K. Viscosities are at either 1 atm or the vapor pressure, whichever is lower. All substances are listed by chemical family in Table 2-6 and by formula in Table 2-7.

Values in this table were taken from the Design Institute for Physical Properties (DIPPR) of the American Institute of Chemical Engineers (AIChE), copyright 2007 AIChE and reproduced with permission of AIChE and of the DIPPR Evaluated Process Design Data Project Steering Committee. Their source should be cited as R. L. Rowley, W. V. Wilding, J. L. Oscarson, Y. Yang, N. A. Zundel, T. E. Daubert, R. P. Danner, DIPPR® Data Compilation of Pure Chemical Properties, Design Institute for Physical Properties, AIChE, New York (2007).

The number of digits provided for values at  $T_{min}$  and  $T_{max}$  was chosen for uniformity of appearance and formatting; these do not represent the uncertainties of the physical quantities, but are the result of calculations from the standard thermophysical property formulations within a fixed format.

**TABLE 2-313 Viscosity of Inorganic and Organic Liquids (Pa-s)**

| Cmpd. no. | Name                 | Formula                                       | CAS no.     | Mol. wt. | C1      | C2      | C3         | C4          | C5      | $T_{min}$ , K | Viscosity at $T_{min}$ | $T_{max}$ , K | Viscosity at $T_{max}$ |

The liquid viscosity is calculated by

$$\mu = \exp(C1 + C2/T + C3 \ln T + C4T^{0.5})$$

where  $\mu$  is the viscosity in Pa·s and  $T$  is the temperature in K. Viscosities are at either 1 atm or the vapor pressure, whichever is higher. All substances are listed by chemical family in Table 2-6 and by formula in Table 2-7.

Values in this table were taken from the Design Institute for Physical Properties (DIPPR) of the American Institute of Chemical Engineers (AIChE), copyright 2007 AIChE and reproduced with permission of AIChE and of the DIPPR Evaluated Process Design Data Project Steering Committee. Their source should be cited as R. L. Rowley, W. V. Wilding, J. L. Oscarson, Y. Yang, N. A. Zundel, T. E. Daubert, R. P. Danner, DIPPR® Data Compilation of Pure Chemical Properties, Design Institute for Physical Properties, AIChE, New York (2007).

The number of digits provided for values at  $T_{min}$  and  $T_{max}$  was chosen for uniformity of appearance and formatting; these do not represent the uncertainties of the physical quantities, but are the result of calculations from the standard thermophysical property formulations within a fixed format.

**TABLE 2-314 Vapor Thermal Conductivity of Inorganic and Organic Substances [W/(m·K)]**

| Cmpd. no. | Name                 | Formula                                       | CAS no.     | Mol. wt. | C1          | C2        | C3          | C4           | $T_{min}$ , K | Thermal cond. at $T_{min}$ | $T_{max}$ , K | Thermal cond. at $T_{max}$ |

The vapor thermal conductivity is calculated by

$$k = \frac{C1T^{C2}}{1 + C3/T + C4/T^2}$$

where  $k$  is the thermal conductivity in W/(m·K) and  $T$  is the temperature in K. Thermal conductivities are at either 1 atm or the vapor pressure, whichever is lower. All substances are listed by chemical family in Table 2-6 and by formula in Table 2-7.

Values in this table were taken from the Design Institute for Physical Properties (DIPPR) of the American Institute of Chemical Engineers (AIChE), copyright 2007 AIChE and reproduced with permission of AIChE and of the DIPPR Evaluated Process Design Data Project Steering Committee. Their source should be cited as R. L. Rowley, W. V. Wilding, J. L. Oscarson, Y. Yang, N. A. Zundel, T. E. Daubert, R. P. Danner, DIPPR® Data Compilation of Pure Chemical Properties, Design Institute for Physical Properties, AIChE, New York (2007).

The number of digits provided for values at  $T_{\min}$  and  $T_{\max}$  was chosen for uniformity of appearance and formatting; these do not represent the uncertainties of the physical quantities, but are the result of calculations from the standard thermophysical property formulations within a fixed format.

**TABLE 2-315 Thermal Conductivity of Inorganic and Organic Liquids [W/(m-K)]**

| Cmpd. no. | Name                 | Formula                                       | CAS no.     | Mol. wt. | C1         | C2           | C3           | C4         | C5          | $T_{min}$ , K | Thermal cond. at $T_{min}$ | $T_{max}$ , K | Thermal cond. at $T_{max}$ |

The liquid thermal conductivity is calculated by

$$k = C1 + C2T + C3T^2 + C4T^3 + C5T^4.$$

where  $k$  is the thermal conductivity in W/(m·K) and  $T$  is the temperature in K. Thermal conductivities are at either 1 atm or the vapor pressure, whichever is higher. All substances are listed by chemical family in Table 2-6 and by formula in Table 2-7.

Values in this table were taken from the Design Institute for Physical Properties (DIPPR) of the American Institute of Chemical Engineers (AIChE), copyright 2007 AIChE and reproduced with permission of AIChE and of the DIPPR Evaluated Process Design Data Project Steering Committee. Their source should be cited as R. L. Rowley, W. V. Wilding, J. L. Oscarson, Y. Yang, N. A. Zundel, T. E. Daubert, R. P. Danner, DIPPR® Data Compilation of Pure Chemical Properties, Design Institute for Physical Properties, AIChE, New York (2007).

The number of digits provided for values at  $T_{\min}$  and  $T_{\max}$  was chosen for uniformity of appearance and formatting; these do not represent the uncertainties of the physical quantities, but are the result of calculations from the standard thermophysical property formulations within a fixed format.

\*An approximate interpolation scheme is to plot the logarithm of the viscosity or the thermal conductivity versus the logarithm of the absolute temperature. At 250 K the viscosity of gaseous argon is to be read as  $1.95 \times 10^{-5}$  Pa·s = 0.0000195 N·s/m<sup>2</sup>.

TABLE 2-317 Lower and Upper Flammability Limits, Flash Point, and Autoignition Temperature for Selected Hydrocarbons

LFL and UFL are lower and upper flammability limits respectively in volume percent fuel in air. Values in this table were taken from the Design Institute for Physical Properties (DIPPR) of the American Institute of Chemical Engineers (AIChE), copyright 2007 AIChE and reproduced with permission of AIChE, the DIPPR Environmental Safety Property Data and Estimations Steering Committee and of the DIPPR Evaluated Process Design Data Project Steering Committee. Their source should be cited as T. N. Rogers, D. A. Zei, R. L. Rowley, W. V. Wilding, J. L. Oscarson, Y. Yang, N. A. Zundel, T. E. Daubert, R. P. Danner, DIPPR® Data Compilation of Pure Chemical Properties, Design Institute for Physical Properties, AIChE, New York (2007). Flammability limits are from B. Lewis and G. Von Elbe, *Combustion, Flames and Explosions of Gases*, New York: Harcourt Brace Jovanovich (1987). Flash point data are from N. I. Sax, *Dangerous Properties of Industrial Materials*, 6th ed., New York: Van Nostrand Reinhold (1984). Autoignition data are from I. Glassman, *Combustion*, 3d ed., New York: Academic Press (1996). The ratings reflect DIPPR® ESP's effort to provide a critical evaluation and quality assessment of each data point with 15 being the highest score possible. The rating is not directly correlated with the estimated experimental uncertainty.

2-448 PHYSICAL AND CHEMICAL DATA

TABLE 2-318 Viscosities of Liquids: Coordinates for Use with Fig. 2-32

| Liquid                         | X    | Y    | Liquid                    | X    | Y    |
|--------------------------------|------|------|---------------------------|------|------|
| Acetaldehyde                   | 15.2 | 4.8  | Freon-113                 | 12.5 | 11.4 |
| Acetic acid, 100%              | 12.1 | 14.2 | Glycerol, 100%            | 2.0  | 30.0 |
| Acetic acid, 70%               | 9.5  | 17.0 | Glycerol, 50%             | 6.9  | 19.6 |
| Acetic anhydride               | 12.7 | 12.8 | Heptane                   | 14.1 | 8.4  |
| Acetone, 100%                  | 14.5 | 7.2  | Hexane                    | 14.7 | 7.0  |
| Acetone, 35%                   | 7.9  | 15.0 | Hydrochloric acid, 31.5%  | 13.0 | 16.6 |
| Acetonitrile                   | 14.4 | 7.4  | Iodobenzene               | 12.8 | 15.9 |
| Acrylic acid                   | 12.3 | 13.9 | Isobutyl alcohol          | 7.1  | 18.0 |
| Allyl alcohol                  | 10.2 | 14.3 | Isobutyric acid           | 12.2 | 14.4 |
| Allyl bromide                  | 14.4 | 9.6  | Isopropyl alcohol         | 8.2  | 16.0 |
| Allyl iodide                   | 14.0 | 11.7 | Isopropyl bromide         | 14.1 | 9.2  |
| Ammonia, 100%                  | 12.6 | 2.0  | Isopropyl chloride        | 13.9 | 7.1  |
| Ammonia, 26%                   | 10.1 | 13.9 | Isopropyl iodide          | 13.7 | 11.2 |
| Amyl acetate                   | 11.8 | 12.5 | Kerosene                  | 10.2 | 16.9 |
| Amyl alcohol                   | 7.5  | 18.4 | Linseed oil, raw          | 7.5  | 27.2 |
| Aniline                        | 8.1  | 18.7 | Mercury                   | 18.4 | 16.4 |
| Anisole                        | 12.3 | 13.5 | Methanol, 100%            | 12.4 | 10.5 |
| Arsenic trichloride            | 13.9 | 14.5 | Methanol, 90%             | 12.3 | 11.8 |
| Benzene                        | 12.5 | 10.9 | Methanol, 40%             | 7.8  | 15.5 |
| Brine, CaCl <sub>2</sub> , 25% | 6.6  | 15.9 | Methyl acetate            | 14.2 | 8.2  |
| Brine, NaCl, 25%               | 10.2 | 16.6 | Methyl acrylate           | 13.0 | 9.5  |

\*Compiled by P. E. Liley from tables of specific heat at constant pressure, thermal conductivity, and viscosity given in SI units for integral kelvin temperatures and pressures in bars by Vasserman. *Thermophysical Properties of Air and Its Components and Thermophysical Properties of Liquid Air and Its Components*. Nauka, Moscow, and in translated form by the National Bureau of Standards, Washington. The number of significant figures given above reflects the similar numbers appearing for the constituent properties in the source references. While reasonable agreement occurs for atmospheric pressure with some other works, the fragmentary data available for the saturated, etc., states show large deviations.

TABLE 2-322 Prandtl Number of Liquid Refrigerants\*

| Refrigerant                                   | No.  | Temperature, K |       |       |      |      |      |      |      |      |      |      |
|---|------|----------------|-------|-------|------|------|------|------|------|------|------|------|

## 2-456 PHYSICAL AND CHEMICAL DATA

In this table are a representative selection of diffusion coefficients. The subsection "Prediction and Correlation of Physical Properties" should be consulted for estimation techniques. As general references, the works by Hirschfelder, Curtiss, and Bird, *Molecular Theory of Gases and Liquids*, Wiley, New York, 1964; Chapman and Cowling, *The Mathematical Theory of Non-Uniform Gases*, Cambridge, New York, 1970; Reid and Sherwood, *The Properties of Gases and Liquids*,

McGraw-Hill, New York, 1964; and Bretsznajder, *Prediction of Transport and Other Physical Properties of Fluids*, Pergamon, New York, 1971, may be found useful. The most exhaustive recent compilation for gases is by Mason and Marrero, *J. Phys. Chem. Ref. Data*, 1 (1972). Unfortunately, the Mason and Marrero work cites only equations and equation constants and not direct tabulations. For these, the Landolt-Börnstein series is suggested.

**TABLE 2-325 Diffusivities in Liquids (25 °C)**

Dilute solutions and 1 atm unless otherwise noted; use  $D_i\mu/T = \text{constant}$  to estimate effect of temperature; ° indicates that reference gives effect of concentration.

\* Especially at low temperatures, the thermal conductivity can often be markedly reduced by even small traces of impurities. This table, for the highest-purity specimens available, should thus be used with caution in applications with commercial materials. From Perry, *Engineering Manual*, 3d ed., McGraw-Hill, New York, 1976. A more detailed table appears as Section 5.5.6 in the *Heat Exchanger Design Handbook*, Hemisphere Pub. Corp., Washington, DC, 1983.

† Parallel to basal plane.

‡ Perpendicular to basal plane.

§ Also known as Teflon, etc.

| Vermiculite       | 120                        |            | 0.84                     | 0.06                          | 0.60   |

NOTE: Difficulties of accurately characterizing many of the specimens mean that many of the values presented here must be regarded as being of order of magnitude only. For some materials, actual measurement may be the only way to obtain data of the required accuracy. To convert kilograms per cubic meter to pounds per cubic foot, multiply by 0.062428; to convert kilojoules per kilogram-kelvin to British thermal units per pound-degree Fahrenheit, multiply by 0.23885.

## PREDICTION AND CORRELATION OF PHYSICAL PROPERTIES\*

### INTRODUCTION

Physical property values, sufficiently accurate for many engineering applications, can be estimated in the absence of reliable experimental data. The purpose of this subsection is to provide a set of recommended prediction methods for general engineering use; it is not a comprehensive review, and many alternative methods are available in the literature. Methods recommended were selected on the basis of accuracy, generality, and, in most cases, simplicity. They generally correspond to the methods tested and given priority in the DIPPR® 801 database project.†

Properties included in this subsection are divided into 10 categories: (1) physical constants: critical properties, normal melting and boiling points, acentric factor, radius of gyration, and dipole moment; (2) vapor

pressure: liquid and solid; (3) thermal properties: enthalpy and Gibbs' energy of formation and ideal gas entropy; (4) latent enthalpy: vaporization, fusion, and sublimation; (5) heat capacity: ideal gas, gas, liquid, and solid; (6) density: gas, liquid, and solid; (7) viscosity: gas and liquid; (8) thermal conductivity: gas and liquid; (9) surface tension; and (10) flammability properties: flash point, flammability limits, and autoignition temperature. Each of the 10 subsections provides a definition of the relevant properties and a description of one or more recommended prediction methods. Each description lists the type of method, its uncertainty, its limitations, and the expected uncertainty of the predicted value. A numerical example is also given to illustrate use of the method. For brevity, symbols used for physical properties and for variables and constants in the equations are defined under Nomenclature and are not generally defined after their use except where doing so clarifies usage. A list of equation and table numbers in which variables appear is included in the Nomenclature section for quick cross-referencing. Although emphasis is on pure-component properties, some mixture estimation techniques have been included for physical constants, density, viscosity, thermal conductivity, surface tension, and flammability. Correlation and estimation of properties that are inherently multicomponent (e.g., diffusion coefficients, mixture excess properties, activity coefficients, etc.) are treated elsewhere in the Handbook.

\*Some material in this subsection has been retained from the corresponding subsection in the Seventh Edition, which was coauthored by Thomas E. Daubert and Evan Buck.

†The Design Institute for Physical Properties (DIPPR®) is an industrial consortium under the auspices of AIChE; Project 801, Evaluated Process Design Data, is a pure-component database of industrially important compounds.

## UNITS

The International Metric System (SI) of units has been used throughout this subsection. Where possible, the estimation equations are set up in dimensionless groups. This makes transparent any conversion factors that should be applied to obtain the property in a desired set of units and eliminates the requirement of specific units for variables. For example, rather than use  $P_c$  as a variable with defined units, the dimensionless group  $P_c/P_a$  is used. When a value for  $P_c$  expressed in

any units (say,  $P_c = 6.53$  MPa) is inserted into this group, the result is dimensionless with an explicit indication of conversion factors that must be included:

$$\frac{P_c}{P_a} = \frac{6.53 \text{ MPa}}{\text{Pa}} = \left( \frac{6.53 \text{ MPa}}{\text{Pa}} \right) \left( \frac{10^6 \text{ Pa}}{\text{MPa}} \right) = 6.53 \times 10^6$$

Section 1 of this handbook should be used for appropriate unit conversion factors.

## Nomenclature

| Physical constants      | Definition  | Value   |
|-------------------------|---|---|
| $h$                     | Planck's constant                                     | $6.626 \times 10^{-34} \text{ J}\cdot\text{s}$                    |
| $k$                     | Boltzmann's constant                                  | $1.3806 \times 10^{-23} \text{ J}/(\text{molecule}\cdot\text{K})$ |
| $N_A$                   | Avogadro's number                                     | $6.022 \times 10^{26} \text{ molecule}/\text{kmol}$               |
| $R$                     | Gas constant  | $8.3143 \text{ Pa}\cdot\text{m}^3/(\text{kmol}\cdot\text{K})$     |
| Properties              | Definition  | Typical units   |
| $A, B, C$               | Molecular principal moments of inertia                | $\text{kg}\cdot\text{m}^2$  |
| $B, B(T)$               | Second virial coefficient                             | $\text{m}^3/\text{kmol}$  |
| $B_m$                   | Second virial coefficient for a mixture               | $\text{m}^3/\text{kmol}$  |
| $C_p$                   | Constant-pressure molar heat capacity                 | $\text{J}/(\text{kmol}\cdot\text{K})$                             |
| $C_{p,i}$               | Ideal gas constant-pressure molar heat capacity       | $\text{J}/(\text{kmol}\cdot\text{K})$                             |
| $C_v$                   | Constant-volume molar heat capacity                   | $\text{J}/(\text{kmol}\cdot\text{K})$                             |
| $H_i$                   | Enthalpy of compound $i$                              | $\text{J}/\text{kmol}$  |
| $k$                     | Thermal conductivity                                  | $\text{W}/(\text{m}\cdot\text{K})$                                |
| $k_b$                   | Thermal conductivity at $T_b$                         | $\text{W}/(\text{m}\cdot\text{K})$                                |
| LFL                     | Lower flammability limit                              | %   |
| $M$                     | Molecular weight                                      | $\text{kg}/\text{kmol}$   |
| $P$                     | Pressure  | Pa  |
| $P$                     | Parachor  | unitless  |
| $P_c$                   | Critical pressure                                     | Pa  |
| $P_r$                   | Reduced pressure; $P_r = P/P_c$                       | unitless  |
| $P^*$                   | Vapor pressure  | Pa  |
| $P^*_{\text{meas}}$     | Measured vapor pressure value                         | Pa  |
| $P_r^*$                 | Reduced vapor pressure; $P_r^* = P^*/P_c$             | unitless  |
| $P_t^*$                 | Vapor pressure at triple point                        | Pa  |
| $R_g$                   | Radius of gyration                                    | m   |
| $S^{\circ}$             | Ideal gas entropy                                     | $\text{J}/(\text{kmol}\cdot\text{K})$                             |
| $S^{\circ}$             | Standard state entropy                                | $\text{J}/(\text{kmol}\cdot\text{K})$                             |
| $S_r$                   | Rotational contribution to entropy                    | $\text{J}/(\text{kmol}\cdot\text{K})$                             |
| $S_{\text{vib}}$        | Vibrational contribution to entropy                   | $\text{J}/(\text{kmol}\cdot\text{K})$                             |
| $T$                     | Temperature   | K   |
| $T_b$                   | Normal boiling point temperature                      | K   |
| $T_{br}$                | Reduced temperature at $T_b$ ; $T_{br} = T_b/T_c$     | unitless  |
| $T_c$                   | Critical temperature                                  | K   |
| $T_m$                   | Melting temperature                                   | K   |
| $T_{\text{meas}}$       | $T$ at which a dependent property was measured        | K   |
| $T_r$                   | Reduced temperature; $T_r = T/T_c$                    | unitless  |
| $T_t$                   | Triple point temperature                              | K   |
| UFL                     | Upper flammability limit                              | %   |
| $V$                     | Molar volume  | $\text{m}^3/\text{kmol}$  |
| $V_m$                   | Mixture molar volume                                  | $\text{m}^3/\text{kmol}$  |
| $V_r$                   | Reduced volume; $V_r = ZT_r/P_r$                      | unitless  |
| $w_i$                   | Mass fraction of component $i$                        | unitless  |
| $x_i$                   | Mole fraction of component $i$                        | unitless  |
| $y_i$                   | Mole fraction of component $i$ in vapor phase         | unitless  |
| $Z$                     | Compressibility factor; $Z = PV/RT$                   | unitless  |
| $Z_c$                   | Critical compressibility factor; $Z_c = P_c V_c/RT_c$ | unitless  |
| $Z_i$                   | Compressibility factor of reference fluid $i$         | unitless  |
| $\Delta G_f^{\circ}$    | Ideal gas standard Gibbs energy of formation          | $\text{J}/\text{kmol}$  |
| $\Delta G_f^{\circ}$    | Standard state Gibbs energy of formation              | $\text{J}/\text{kmol}$  |
| $\Delta H_f^{\circ}$    | Ideal gas standard enthalpy of formation              | $\text{J}/\text{kmol}$  |
| $\Delta H_f^{\circ}$    | Standard state enthalpy of formation                  | $\text{J}/\text{kmol}$  |
| $\Delta H_{\text{fus}}$ | Enthalpy of fusion                                    | $\text{J}/\text{kmol}$  |
| $\Delta H_{\text{rxn}}$ | Enthalpy change per mole of reaction as written       | $\text{J}/\text{kmol}$  |
| $\Delta H_{\text{sub}}$ | Enthalpy of sublimation                               | $\text{J}/\text{kmol}$  |
| $\Delta H_v$            | Enthalpy of vaporization                              | $\text{J}/\text{kmol}$  |
| $\Delta S_f^{\circ}$    | Standard state entropy of formation                   | $\text{J}/(\text{kmol}\cdot\text{K})$                             |
| $\Delta S_f^{\circ}$    | Ideal gas entropy of formation                        | $\text{J}/(\text{kmol}\cdot\text{K})$                             |
| $\Delta S_{\text{fus}}$ | Latent entropy of fusion                              | $\text{J}/(\text{kmol}\cdot\text{K})$                             |
| $\Delta Z_v$            | Change in compressibility factor upon vaporization    | unitless  |
| $\rho$                  | Molar density; $\rho = V^{-1}$                        | $\text{kmol}/\text{m}^3$  |
| $\rho_c$                | Critical molar density; $\rho_c = V_c^{-1}$           | $\text{kmol}/\text{m}^3$  |

**Nomenclature** (*Continued*)

| Properties              | Definition   | Typical units   |
|-------------------------|--|---|
| $\rho_r$                | Reduced molar density; $\rho_r = \rho/\rho_c$  | unitless  |
| $\omega$                | Acentric factor  | unitless  |
| $\eta$                  | Viscosity  | Pa·s  |
| $\eta^o$                | Viscosity at low pressure  | Pa·s  |
| $\sigma$                | Surface tension  | mN/m  |
| $\sigma_m$              | Surface tension of mixture   | mN/m  |
| $\tau$                  | Complementary reduced temperature ( $= 1 - T_r$ )  | unitless  |
| $\tau_b$                | Complementary reduced normal boiling temperature ( $= 1 - T_{br}$ )                          | unitless  |
| $\mu$                   | Dipole moment  | D   |
| $\mu_r$                 | Reduced dipole moment [defined in Eq. (2-62)]  | unitless  |
| Eq. variables           | Definition   | (Equations), [Tables]   |
| $a$                     | EoS constant   | (2-66), [2-354]   |
| $a, b, c, \dots$        | GC values for $C_p$ and $\eta$   | (2-51), (2-52), (2-53),<br>(2-97), [2-356]  |
| $a, b, c$               | Correlation coefficients   | (2-21), (2-23)  |
| $a_i$                   | GC values  | (2-43), (2-97), [2-346, 2-356]  |
| $a, b$                  | Terms in second virial correlation   | (2-61)  |
| $a, b$                  | Chickos correlation parameters   | (2-39), (2-40), (2-41)  |
| $a_i, b_i, d_i$         | GC values for liquid $C_p$   | (2-51), [2-348]   |
| $\bar{a}, \bar{\alpha}$ | EoS constant for mixture   | (2-76)  |
| $A, B, C, \dots$        | Correlation constants/parameters   | (2-2), (2-20), (2-22),<br>(2-34), (2-36), (2-50), (2-65),<br>(2-68), (2-83), (2-85),<br>(2-87), (2-88), (2-95),<br>(2-96), (2-101), above (2-114) |
| $A$                     | Factor in liquid $k$ correlation   | (2-108), [2-358]  |
| $A_i$                   | Constants in $C_p^o$ correlation   | (2-45), (2-46)  |
| $b$                     | EoS constant   | (2-66), [2-354]   |
| $b_b, c_b, \dots$       | Reference EoS constants  | (2-65), [2-353]   |
| $\bar{b}_i$             | GC value for AIT   | (2-124), [2-363, 2-364]   |
| $\bar{b}$               | EoS constant for mixture   | (2-75)  |
| $B^{(i)}$               | Second virial expansion terms  | (2-58), (2-59), (2-60),<br>(2-61)   |
| $C$                     | Number of components in mixture  | (2-55), (2-72), (2-73),<br>(2-74), (2-75), (2-76),<br>(2-77), (2-80), (2-81),<br>(2-82), (2-98), (2-113), (2-119)                                 |
| $C_i$                   | GC values for $T_b$ or $\eta$  | (2-15), (2-87), [2-341, 2-355]  |
| $C_{i,int}$             | Sum of intramolecular group-group interactions   | (2-16)  |
| $C_{ij}$                | Group-group intramolecular interaction pair  | (2-16), [2-342]   |
| $(C_p^o)_i$             | GC values for ideal gas heat capacity  | (2-49), [2-347]   |
| $C_{sj}$                | Chickos: GC value for C—H group  | (2-41), [2-344]   |
| $C_{tj}$                | Chickos: GC value for functional group   | (2-41), [2-345]   |
| $f_i$                   | Halogen correction for $\Delta H_{sub}$ correlation  | (2-43), [2-346]   |
| $f^{(i)}$               | Vapor pressure deviation function  | (2-25)  |
| $F$                     | Factor in surface tension equation   | (2-116), (2-117)  |
| $G_{ij}$                | Adjustable mixture viscosity parameter   | (2-98)  |
| $g_{sr}^E$              | UNIFAC combinatorial excess Gibbs energy   | (2-99)  |
| $g_r^E$                 | UNIFAC residual excess Gibbs energy  | (2-99)  |
| $h$                     | Parameter in Riedel vapor pressure equation  | following (2-24)  |
| $K$                     | Parameter in Riedel vapor pressure equation  | following (2-24)  |
| $LFL_i$                 | GC contribution  | (2-122), [2-361, 2-362]   |
| $n$                     | Number of nonhydrogen atoms  | (2-15)  |
| $n_A$                   | Number of atoms in molecule  | (2-1), (2-30), (2-31), (2-48)   |
| $n_E$                   | Number of occurrences of element $E$ in compound   | (2-54)  |
| $n_i$                   | Number of occurrences of group $i$   | (2-27), (2-43), (2-49),<br>(2-51), (2-53),<br>(2-87), (2-109),<br>(2-115), (2-122),<br>(2-123), (2-124)   |
| $n_f$                   | Chickos: no. of different functional groups  | (2-41)  |
| $n_s$                   | Chickos: no. of different nonring or aromatic C—H groups bonded to functional groups         | (2-41)  |
| $n_x$                   | Total no. of halogen and H atoms attached to C and Si atoms for $\Delta H_{sub}$ correlation | (2-43)  |
| $N$                     | Total number of groups in molecule   | (2-12), (2-15) (2-16),<br>(2-43), (2-49), (2-51),<br>(2-53), (2-54), (2-87),<br>(2-97), (2-109), (2-115)  |
| $N_C$                   | Number of C atoms  | (2-121)   |
| $N_f^i$                 | Chickos: no. of functional groups of type $i$  | (2-41)  |
| $N_g^i$                 | Chickos: no. of C—H groups of type $i$ bonded to other C atoms                               | (2-41)  |
| $N_H$                   | Number of H atoms  | (2-121)   |

## Nomenclature (Continued)

| Eq. variables                  | Definition   | (Equations), [Tables]                          |
|--------------------------------|--|--|
| $N_{CR}$                       | Chickos: no. of CH <sub>2</sub> groups in nonaromatic ring to form cyclic paraffin of same ring size | (2-40)   |
| $N_O$                          | Chickos: Number of O atoms   | (2-121)  |
| $N_R$                          | Chickos: no. of nonaromatic rings  | (2-40)   |
| $N_S$                          | Chickos: Number of S atoms   | (2-121)  |
| $N_{S_i}$                      | Chickos: no. of C—H groups of type $i$ bonded to at least one functional group                       | (2-41)   |
| $N_X$                          | Number of halogen atoms  | (2-121)  |
| $\bar{P}_c$                    | Pseudocritical pressure for mixture  | (2-73)   |
| $P_{c,ij}$                     | Cross term in mixing rule  | (2-79)   |
| $q$                            | Rackett equation power for $Z_c$   | (2-69), (2-70), (2-81)                         |
| $q_i$                          | UNIFAC molecular surface area  | following (2-100)                              |
| $Q_k$                          | UNIFAC group surface area  | following (2-100)                              |

**CLASSIFICATION OF ESTIMATION METHODS**

Physical property estimation methods may be classified into six general areas: (1) theory and empirical extension of theory, (2) corresponding states, (3) group contributions, (4) computational chemistry, (5) empirical and quantitative structure property relations (QSPR) correlations, and (6) molecular simulation. A quick overview of each class is given below to provide context for the methods and to define the general assumptions, accuracies, and limitations inherent in each.

**Theory and Empirical Extension of Theory** Methods based on theory generally provide better extrapolation capability than empirical fits of experimental data. Assumptions required to simplify the theory to a manageable equation suggest accuracy limitations and possible improvements, if necessary. For example, the ideal gas isobaric heat capacity, rigorously obtained from statistical mechanics under the assumption of independent harmonic vibrational modes, is [Rowley, R. L., *Statistical Mechanics for Thermophysical Property Calculations*, Prentice-Hall, Englewood Cliffs, N.J., 1994]

$$\frac{C_p^\circ}{R} = \frac{8 - \delta}{2} + \sum_{j=1}^{3n_A - 6 + \delta} \left( \frac{\Theta_j}{T} \right)^2 \frac{e^{\Theta_j/T}}{(e^{\Theta_j/T} - 1)^2}$$

$$\delta = \begin{cases} 0 & \text{nonlinear molecules} \\ 1 & \text{linear molecules} \end{cases} \quad (2-1)$$

where  $\Theta_j$  is the characteristic temperature for the  $j$ th vibrational frequency in a molecule of  $n_A$  atoms. The temperature dependence of this equation is exact to the extent that the frequencies are harmonic. Corrections for anharmonicity can be applied (albeit with difficulty) where warranted.

Extension of theory often requires introduction of empirical models and parameters in lieu of terms that cannot be rigorously calculated. Good accuracy is expected in the region where the model parameters were fitted to experimental data, but only limited accuracy when an empirical model is extrapolated to other conditions. For example, a simplified theory suggests that vapor pressure should have the form

$$\ln P^\circ = A - \frac{B}{T} \quad (2-2)$$

where the empirical parameter  $B$  is given by

$$B = \frac{\Delta H_v}{R\Delta Z_v} \quad (2-3)$$

and  $\Delta H_v$  and  $\Delta Z_v$  are differences between the vapor and liquid enthalpies and compressibility factors, respectively. Vapor pressures over a narrow temperature range can be effectively correlated using Eq. (2-2), but this equation should not be used to extrapolate vapor pressures over a wide range of temperatures.

**Corresponding States (CS)** The principle of CS applies to conformal fluids [Leland, T. L., Jr., and P. S. Chappelaar, *Ind. Eng. Chem.*, **60** (1968): 15]. Two fluids are conformal if their intermolecular interactions are equivalent when scaled in dimensionless form. For example, the Lennard-Jones (LJ) intermolecular pair potential energy  $U$  can be written in dimensionless form as

$$U^\circ = 4[(r^\circ)^{-12} - r^\circ^{-6}] \quad (2-4)$$

where  $r^\circ = r/\sigma$ ,  $U^\circ = U/\epsilon$ ,  $\sigma$  is the LJ size parameter, and  $\epsilon$  is the LJ attractive well depth parameter. At equivalent scaled temperatures  $kT/\epsilon$  ( $k$  is Boltzmann's constant) and pressures  $P\sigma^3/\epsilon$ , all LJ fluids will have identical dimensionless properties because the molecules interact through the identical scaled intermolecular potential given by Eq. (2-4). Generalization of this scaling principle is commonly done using critical temperature  $T_c$  and critical pressure  $P_c$  as scaling factors. At the same reduced coordinates ( $T_r = T/T_c$  and  $P_r = P/P_c$ ) all conformal fluids will have the same dimensionless properties; for example,  $Z = Z(T_r, P_r)$  where the compressibility factor is defined as  $Z = PV/RT$ . A correlation of experimental data for one fluid can be used as the reference for the properties of all conformal fluids. Nonconformality is the main accuracy limitation. For instance, interactions between non-spherical or polar molecules may not be adequately represented by Eq. (2-4), and so the scaled properties of these fluids will not conform to those of a fluid with interactions well represented by Eq. (2-4). A correction for nonconformality is usually made by the addition of one or more reference fluids whose deviations from the first reference fluid are used to characterize the effect of nonconformality. For example, in the Lee-Kesler method [Lee, B. I., and M. G. Kesler, *AIChE J.*, **21** (1975): 510] *n*-octane is used as a second, nonspherical reference fluid, and deviations of *n*-octane scaled properties from those of the spherical reference fluid at equivalent reduced conditions are assumed to be a linear function of the acentric factor. An extended Lee-Kesler method [Wilding, W. V., and R. L. Rowley, *Int. J. Thermophys.*, **7** (1986): 525] uses three reference fluids: *n*-octane to correct for size-shape nonconformality relative to methane and water to correct for polar effects. Some CS methods [e.g., Teja, A., S. I. Sandler, and N. C. Patel, *Chem. Eng. J.*, **21** (1981): 21] utilize different reference fluids for different classes of fluids to maintain close conformality between the fluid whose properties are to be estimated and the reference fluids.

**Group Contributions (GC)** Chemical and physical properties generally correlate well with molecular structure. GC methods assume a summative behavior of the structural groups of the constituent molecules. For example, ethanol ( $\text{CH}_3\text{—CH}_2\text{—OH}$ ) properties would be obtained as the sum of contributions from the  $\text{—CH}_3$ ,  $\text{—CH}_2$ , and  $\text{—OH}$  groups. The contribution of each group is obtained by regression of experimental data that include as many different compounds containing that group as possible. Structural groups must be used exactly as defined in the original correlation. A general principle in deciding how to make the groupings is to give the more specific group priority. For example, although the structural piece  $\text{—COOCH}_3$  is ambiguous in a methyl ester, a more specific group value available for an ester  $\text{—COO—}$  would take precedence over a combination the two smaller groups  $\text{—(C=O)—}$  and

—O— whose values were most likely regressed only from ketone and ether data, respectively. Excellent accuracy can usually be expected from GC methods when group values were regressed from large quantities of experimental data. However, if the ratio of number of groups to regressed experimental data is large, significant errors can result when the method is applied to new compounds (extrapolation). Such excessive specificity in the group definitions leads to poor extrapolation capabilities even though the fit of the regressed data may be excellent.

**Computational Chemistry (CC)** Commercial software is available that solves the Schrödinger equation for approximate forms of the wave function. Various levels of sophistication (termed *model chemistry*) for the wave function can be chosen at the expense of computational time. Results include structural information (bond lengths, bond angles, dihedral angles, etc.), electron/charge distribution information, internal vibrational modes (for ideal gas properties), and energy of the molecule, valid for the chosen model chemistry. Because calculations are performed on individual molecules, they are primarily suited for ideal gas properties. Relative energies for the same model chemistry are more accurately obtained than absolute energies, so enthalpies and entropies of reaction are common industrial uses of CC predictions in addition to individual structural and ideal gas properties.

**Empirical QSPR Correlations** In quantitative structure property relationship (QSPR) methods, physical properties are correlated with molecular descriptors that characterize the molecular and electronic structure of the molecule. Large amounts of experimental data are used to statistically determine the most significant descriptors to be used in the correlation and their contributions. The resultant correlations are simple to apply if the descriptors are available. Descriptors must generally be generated by the user with computational chemistry software, although the DIPPR® 801 database now contains a table of molecular descriptors for most of the compounds in it. QSPR methods are often very accurate for specific families of compounds for which the correlation was developed, but extrapolation problems are even more of an issue than with GC methods.

**Molecular Simulations** Molecular simulations are useful for predicting properties of bulk fluids and solids. Molecular dynamics (MD) simulations solve Newton's equations of motion for a small number (on the order of  $10^3$ ) of molecules to obtain the time evolution of the system. MD methods can be used for equilibrium and transport properties. Monte Carlo (MC) simulations use a model for the potential energy between molecules to simulate configurations of the molecules in proportion to their probability of occurrence. Statistical averages of MC configurations are useful for equilibrium properties, particularly for saturated densities, vapor pressures, etc. Property estimations using molecular simulation techniques are not illustrated in the remainder of this section as commercial software implementations are not generally available at this time.

## PHYSICAL CONSTANTS

**Critical Properties** The critical temperature  $T_c$ , pressure  $P_c$ , and volume  $V_c$  of a compound are important, widely used constants. They are important in determining the phase boundaries of a compound and (particularly  $T_c$  and  $P_c$ ) are required input parameters for most thermal and volumetric property calculations of the equilibrium phases using CS or analytical equations of state. Most estimation methods employ weighted group, atom, or bond contributions.

The critical temperature of a compound is the temperature above which a liquid phase cannot be formed, no matter the pressure of the system. The critical pressure is the vapor pressure of the compound at the critical temperature. The critical volume is the volume occupied by a set amount of a compound (typically 1 mol) at its critical temperature and pressure.

The critical compressibility factor  $Z_c$  is determined from the experimental or predicted values of the critical properties by the definition

$$Z_c = \frac{P_c V_c}{RT_c} \quad (2-5)$$

## Recommended Methods

**Organic molecules:** The Ambrose method is recommended for all three critical properties of hydrocarbons and *n*-alcohols. The Joback method is recommended for  $T_c$  and  $P_c$  of all other organic molecules. Fedors' method is recommended for  $V_c$  of these compounds, but the Joback method can also be used.

**Inorganic molecules:** The simple correlation  $T_c = 1.64T_b$  is recommended if the normal boiling point is known. Critical pressure  $P_c$  is best obtained by extrapolating vapor pressure data to  $T_c$ , and  $V_c$  is best obtained from a correlation of liquid density extrapolated to  $T_c$ .

Other recent methods including the Wilson-Jaspersion (Wilson, G. M., and L.V. Jaspersion, *Critical Constants  $T_c$ ,  $P_c$ , Estimation Based on Zero, First and Second Order Methods*, AIChE Spring Meeting, New Orleans, La., 1996) and Marrero-Pardillo [Marrero-Morejon, J., and E. Pardillo-Fontdevila, *AIChE J.*, **45** (1999): 615] methods have proved to be as good as or better for some classes of compounds than the methods presented here; however, their application is more difficult.

**Method:** Ambrose method.

**Reference:** Ambrose, D., Correlation and Estimation of Vapour-Liquid Critical Properties. I. Critical Temperatures of Organic Compounds, *Natl. Phys. Lab. Report Chem.* **92** (1978); Correlation and Estimation of Vapour-Liquid Critical Properties. II. Critical Pressures and Volumes of Organic Compounds, *Natl. Phys. Lab Report Chem.* **98** (1979).

**Classification:** Group contributions.

**Expected uncertainty:** ~6 K for  $T_c$  (about 1 percent), ~2 bar for  $P_c$  (about 5 percent), ~8 cm<sup>3</sup>/mol for  $V_c$  (about 3 percent).

**Applicability:** Organic compounds.

**Input data:**  $T_b$ ,  $M$ , group contributions  $\Delta_T$ ,  $\Delta_P$ , and  $\Delta_V$  from Table 2-336.

**Description:** A GC method with first-order contributions and corrections (delta Platt number) for branched alkanes. Variables  $T_c$ ,  $P_c$ , and  $V_c$  are given by the following relations:

$$T_c = T_b \left[ 1 + \left( 1.242 + \sum \Delta_T \right)^{-1} \right] \quad (2-6)$$

$$\frac{P_c}{\text{bar}} = \frac{M}{\text{kg/kmol}} \left( 0.339 + \sum \Delta_P \right)^{-2} \quad (2-7)$$

$$\frac{V_c}{\text{cm}^3/\text{mol}} = 40 + \sum \Delta_V \quad (2-8)$$

**Example** Use the Ambrose method to estimate the critical constants of 2,2,4-trimethylpentane.

**Required data:** From the DIPPR® 801 database,  $T_b = 372.39$  K and  $M = 114.229$  kg/kmol.

**Structure:**

Group contributions from Table 2-336:

| Group             | $n_i$ | $\Delta_T$ | $\Delta_P$ | $\Delta_V$ |
|-------------------|-------|------------|------------|------------|
| Alkyl carbons     | 8     | 0.138      | 0.226      | 55.1       |
| >CH— (correction) | 1     | -0.043     | -0.006     | -8         |
| >C< (correction)  | 1     | -0.120     | -0.030     | -17        |
| Delta Platt no.   | 0     | -0.023     | -0.026     | —          |

Calculations using Eqs. (2-6), (2-7), and (2-8):

$$\sum \Delta_T = (8)(0.138) + (1)(-0.043) + (1)(-0.120) = 0.941$$

$$T_c = T_b(1.4581) = (372.39 \text{ K})(1.4581) = 543.0 \text{ K}$$

$$\sum \Delta_P = (8)(0.226) + (1)(-0.006) + (1)(-0.030) = 1.772$$

$$\frac{P_c}{\text{bar}} = \frac{M}{\text{kg/kmol}} \left( 0.339 + \sum \Delta_P \right)^{-2} = \frac{114.229}{(0.339 + 1.772)^2} = 25.63$$

$$P_c = 25.63 \text{ bar}$$

**TABLE 2-336 Ambrose Group<sup>a</sup> Contributions for Critical Constants**

| Group  | $\Delta_T$ | $\Delta_P$ | $\Delta_V$ |
|--|------------|------------|------------|
| Carbon atoms in alkyl groups   | 0.138      | 0.226      | 55.1       |

<sup>a</sup>Ambrose, D., Correlation and Estimation of Vapour-Liquid Critical Properties. I. Critical Temperatures of Organic Compounds, *Natl. Phys. Lab Report Chem.* **92** (1978); Correlation and Estimation of Vapour-Liquid Critical Properties. II. Critical Pressures and Volumes of Organic Compounds, *Natl. Phys. Lab Report Chem.* **98** (1979).

<sup>b</sup>The delta Platt number is defined as the Platt number of the isomer minus the Platt number of the corresponding alkane. (For *n*-alkanes the Platt number is *n* - 3.) The Platt number is the total number of groups of four carbon atoms three bonds apart [Platt, J. R., *J. Chem. Phys.*, **15**(1947): 419; **56**(1952): 328]. This correction is used only for branched alkanes.

<sup>c</sup>Includes naphthenic alcohols and glycols but not aromatic alcohols such as xylenol.

<sup>d</sup>First determine the hydrocarbon homomorph, i.e., substitute —CH<sub>3</sub> for each —OH and calculate  $\sum \Delta_T$  for this compound. Subtract 0.138 from  $\sum \Delta_T$  for each —OH substituted. Next, add  $0.87 - 0.11n + 0.003n^2$  where  $n = [T_c/K(\text{alcohol}) - 314]/19.2$ . Exceptions include methanol ( $\sum \Delta_T = 0$ ), ethanol ( $\sum \Delta_T = 0.939$ ), and any alcohol whose value of *n* exceeds 10.

<sup>e</sup>Determine the hydrocarbon homomorph as in footnote *d*. Calculate  $\sum \Delta_P$  and subtract 0.226 for each —OH substituted. Add  $0.100 - 0.013n$ , where *n* is computed as in footnote *d*.

<sup>f</sup>When estimating the critical volumes of aromatic substances, use ring compound values, if available, and correct for double bonds.

## 2-470 PHYSICAL AND CHEMICAL DATA

$$\sum \Delta_V = (8)(55.1) + (1)(-8) + (1)(-17) = 415.8$$

$$V_c = (40 + 415.8) \text{ cm}^3/\text{mol} = 455.8 \text{ cm}^3/\text{mol}$$

## Results:

| Property                       | DIPPR <sup>®</sup><br>recommended value | Ambrose<br>estimation | %<br>Difference |
|--------------------------------|---|-----------------------|-----------------|
| $T_c/\text{K}$                 | 543.8                                   | 543.0                 | -0.15           |

| $V_c/(\text{cm}^3/\text{mol})$ | 468.0                                   | 455.8                 | -2.6            |

**Method:** Joback method.

**Reference:** Joback, K. G., M.S. Thesis in Chemical Engineering, Massachusetts Institute of Technology, Cambridge, Mass., June 1984.

**Classification:** Group contributions.

**Expected uncertainty:** 7 K (~1 percent) for  $T_c$ ; 2 bar (~5 percent) for  $P_c$ .

**Applicability:** Organic compounds.

**Input data:**  $T_b$ , group contributions  $\Delta_T$ ,  $\Delta_P$ ,  $\Delta_V$  from Table 2-337, and the number of atoms in the molecule  $n_A$ .

**Description:** A GC method with first-order contributions. Variables  $T_c$ ,  $P_c$ , and  $V_c$  are given by the following relations:

$$T_c = T_b \left[ 0.584 + 0.965 \sum \Delta_T - \left( \sum \Delta_T \right)^2 \right]^{-1} \quad (2-9)$$

$$\frac{P_c}{\text{bar}} = \left( 0.113 + 0.0032 n_A - \sum \Delta_P \right)^{-2} \quad (2-10)$$

$$\frac{V_c}{\text{cm}^3/\text{mol}} = 17.5 + \sum \Delta_V \quad (2-11)$$

where  $\Delta_T$ ,  $\Delta_P$ ,  $\Delta_V$  are group contributions from Table 2-337 and  $n_A$  is the number of atoms in the molecule.

**Example** Estimate the critical constants of *o*-xylene by using the Joback method.

**Structure:**

**Required input data:** From the DIPPR<sup>®</sup> 801 database,  $T_b = 417.58 \text{ K}$ . From Table 2-337:

| Group                | $n_i$ | $\Delta_T$ | $\Delta_P$ | $\Delta_V$ |
|----------------------|-------|------------|------------|------------|
| $\text{—CH— (ring)}$ | 4     | 0.0082     | 0.0011     | 41         |
| $\text{>C< (ring)}$  | 2     | 0.0143     | 0.0008     | 32         |
| $\text{—CH}_3$       | 2     | 0.0141     | -0.0012    | 65         |

From Eqs. (2-9), (2-10), and (2-11):

$$\sum \Delta_T = (4)(0.0082) + (2)(0.0143) + (2)(0.0141) = 0.0896$$

$$T_c = T_b [0.584 + 0.965 (0.896) - (0.896)^2]^{-1}$$

$$T_c = T_b (1.5096) = (417.58 \text{ K})(1.5096) = 630.37 \text{ K}$$

$$n_A = 18 \quad \sum \Delta_P = (4)(0.0011) + (2)(0.0008) + (2)(-0.0012) = 0.00360$$

$$\frac{P_c}{\text{bar}} = \left( 0.113 + 0.0032 n_A - \sum \Delta_P \right)^{-2} = [0.113 + (0.0032)(18) - 0.0036]^{-2} = 35.86$$

$$P_c = 35.86 \text{ bar}$$

$$\sum \Delta_V = (4)(41) + (2)(32) + (2)(65) = 358$$

$$V_c = (17.5 + 358) \text{ cm}^3/\text{mol} = 375.5 \text{ cm}^3/\text{mol}$$

TABLE 2-337 Joback \* Group Contributions for Critical Constants

| $V_c/(\text{cm}^3/\text{mol})$ | 269                       | 272.5             | 1.30         |

**Method:** Fedor method.

**Reference:** Fedors, R. F., *AIChE J.*, **25** (1979): 202.

**Classification:** Atom/structure contributions.

**Expected uncertainty:** ~8 cm<sup>3</sup>/mol (3 percent).

**Applicability:** Organic compounds.

**Input data:** Molecular structure, atom and structural increments,  $\Delta_V$  in Table 2-238.

**Description:** An atom contribution method with structural increments for  $V_c$ , given by

$$\frac{V_c}{\text{cm}^3/\text{mol}} = 26.6 + \sum_{i=1}^N n_i \Delta_V \quad (2-12)$$

where  $\Delta_V$  are structural contributions from Table 2-238.

**Example** Use Fedors' method to estimate the critical volume of *sec*-butanol.

**Group contributions from Table 2-238:**

| Group       | $n_i$ | $\Delta_V$ |
|-------------|-------|------------|
| C           | 4     | 34.426     |
| H           | 10    | 9.172      |
| O (alcohol) | 1     | 18.000     |

Calculation using Eq. (2-12):

$$\sum \Delta_V = (4)(34.426) + (10)(9.172) + (1)(18.000) = 247.4$$

$$V_c = (26.6 + 247.4) \text{ cm}^3/\text{mol} = 274.0 \text{ cm}^3/\text{mol}$$

This value differs from the DIPPR® 801 recommended value of 269 cm<sup>3</sup>/mol by 1.9 percent.

**Mixtures** Application of CS methods and analytical equations of state (EoS) to mixtures typically requires pseudocritical temperatures and pressures. These values are obtained from the pure-component critical properties by applying mixing rules specific to the method under consideration. While pseudocritical values should be used for mixture CS and EoS applications, the values are usually quite different from the mixture's true critical properties. A variety of methods are available for estimating true critical properties for mixtures (see PGLA), but only modest accuracy can be expected.

**Normal Melting Point** The *normal melting point* is defined as the temperature at which melting occurs at atmospheric pressure. Methods to estimate the melting point have not been particularly effective because the melting point depends strongly on solid crystal structure and that structure is not effectively correlated with standard GC or CS methods. If the triple point temperature is known, then the melting point is best estimated as being equal to the triple point temperature. However, rarely is the triple point temperature available if the melting point has not also been determined.

**Recommended Method** The method of Constantinou and Gani is recommended with caution.

**Reference:** Constantinou, L., and R. Gani, *AIChE J.*, **40** (1994): 1697.

**Classification:** Group contributions.

**Expected uncertainty:** 25 percent.

**Applicability:** Organic compounds.

**Input data:** First-order and second-order group contributions from molecular structure.

**Description:** A group contribution method given by

$$T_m = (102.425 \text{ K}) \cdot \ln \left( \sum_i N_i t_{m1,i} + \sum_j N_j t_{m2,j} \right) \quad (2-13)$$

where  $N_i, N_j$  = number of first- and second-order groups, respectively

$t_{m1,i}$  = first-order group contributions from Table 2-339

$t_{m2,i}$  = second-order group contributions from Table 2-340

**Example** Estimate the melting point of 2,6-dimethylpyridine.

**Structure and group contributions:**

| Group                               | $N_i$ | $t_{m1,i}$ | $t_{m2,i}$ |
|-------------------------------------|-------|------------|------------|
| -CH <sub>3</sub>                    | 2     | 0.4640     |            |
| -C <sub>5</sub> H <sub>3</sub> (N)- | 1     | 12.6275    |            |
| Six-member ring                     | 1     |            | 1.5656     |

Calculation using Eq. (2-13):

$$T_m = (102.425 \text{ K}) \ln [(2)(0.4640) + 12.6275 + 1.5656] = 278 \text{ K}$$

The predicted value is 4 percent higher than the recommended experimental value of 267 K in the DIPPR® 801 database.

**Normal Boiling Point** The normal boiling temperature  $T_b$  is the temperature at which the vapor pressure of the liquid equals 101.325 kPa (1.0 atm). In some (usually older) literature sources,  $T_b$  values were reported at ambient pressures rather than at 101.325 kPa. If two or more such values are available, they can be used to obtain  $T_b$  by using Eq. (2-2) to linearly interpolate  $\ln P'$  vs.  $1/T$  values.

If there are sufficient vapor pressure data available, then  $T_b$  may be found from a regression of the data using an appropriate vapor pressure equation [e.g., Eqs. (2-21)–(2-26)]. If one or a few vapor pressure data at low pressure are available, a common occurrence, then the method of Pailhes can be used to estimate  $T_b$ . The most accurate method for prediction of normal boiling temperatures without experimental data is the Nannoolal method.

TABLE 2-339 First-Order Groups and Their Contributions for Melting Point\*

\*Constantinou, L., and R. Gani, *AIChE J.*, **40** (1994): 1697.**Recommended Method** Pailhes method.**Classification:** Group contributions.**Expected uncertainty:** 3 K (~1 to 2 percent).**Applicability:** Organic compounds.**Reference:** Pailhes, F., *Fluid Phase Equilib.*, **41** (1988): 97.

**Input data:** Molecular structure and one measured vapor pressure value  $P_{meas}^*$  (often at a low pressure). The method requires estimation of  $T_c$  and  $P_c$  using a group contribution method. The original Pailhes method used the Lydersen method [Lydersen, A. L., *AIChE J.*, **21** (1975): 510], but the Joback method is illustrated here for consistency with the previous examples on critical constant estimation.

**Description:** A simple group contribution method given by

$$T_b = T_{meas} \frac{\log(P_c/\text{bar}) + (1 - T_{br})x_p}{\log(P_c/\text{bar})} - 3x_p - 1.49x_p^2 \quad (2-14)$$

where  $T_b$  = estimate of normal boiling point $P_c$  = critical pressure estimated from group contributions $T_{br}$  = reduced normal boiling point estimated from Eq. (2-9) $x_p = \log(1 \text{ atm}/P_{meas}^*)$  $T_{meas}$  = temperature at which experimental vapor pressure is known

\*Constantinou, L., and R. Gani, *AIChE J.*, **40** (1994): 1697.

**Example** The vapor pressure of *n*-decylacetate at 348.65 K is 106.66 Pa. Estimate the normal boiling point of this compound.

Structure and group contributions from Table 2-337:

| Group            | $n_i$ | $\Delta_r$ | $\Delta_p$ |
|------------------|-------|------------|------------|
| —CH <sub>3</sub> | 2     | 0.0141     | -0.0012    |
| >CH <sub>2</sub> | 9     | 0.0189     | 0          |
| —COO— (ester)    | 1     | 0.0481     | 0.0005     |

Group contribution calculations using Eqs. (2-9) and (2-10):

$$\sum \Delta_r = (2)(0.0141) + (9)(0.0189) + (1)(0.0481) = 0.2464$$

$$T_{br} = 0.584 + 0.965(0.2464) - (0.2464)^2 = 0.76106$$

$$\sum \Delta_p = (2)(-0.0012) + (1)(0.0005) = -0.0019$$

$$n_A = 38 \quad P_c = (0.113 + 0.0032n_A + 0.0019)^2 \text{ bar} = 17.88 \text{ bar} = 17.65 \text{ atm}$$

Calculation of auxiliary quantities:

$$x_p = \log \frac{1 \text{ atm}}{P'_{\text{meas}}} = \log \frac{101325 \text{ Pa}}{106.66 \text{ Pa}} = 2.9777$$

Calculation of normal boiling point using Eq. (2-14):

$$\frac{T_b}{K} = 348.65 \frac{\log 17.88 + (1 - 0.76016)(2.9777)}{\log 17.88} - 3(2.9777) - 1.49(2.9777)^2$$

$$T_b = 525.3 \text{ K}$$

The estimated value is 1.6 percent higher than the DIPPR<sup>®</sup> 801 recommended value of 517.15 K.

**Recommended Method** Nannoolal method.

Reference: Nannoolal, Y., et al., *Fluid Phase Equilib.*, **226** (2004): 45.

Classification: Group contributions.

Expected uncertainty: 7 K (on the order of 2 percent).

Applicability: Organic compounds for which group values are available.

Input data: GC values  $C_i$  in Table 2-341; intramolecular group-group interactions  $C_{ij}$  in Table 2-342.

Description: A GC method that includes second-order corrections for steric effects and intramolecular interactions. Variable  $T_b$  is found from

$$\frac{T_b}{K} = \frac{\sum_{i=1}^N n_i \cdot C_i}{n^{0.6583} + 1.6868} + 84.3395 \quad (2-15)$$

where  $n$  = number of nonhydrogen atoms

$n_i$  = number of occurrences of group  $i$

$N$  = number of groups

$C_i$  = group contribution from Table 2-341 or Eq. (2-16)

Corrections for intramolecular group-group interactions  $C_{i,int}$  are made by dividing the sum of all unique group pairs within the molecule by  $n$ . This can be written as

$$C_{i,int} = \frac{1}{n} \sum_{i=1}^N \sum_{j>i}^N C_{ij} \quad (2-16)$$

or thought of as the sum of terms in the upper half (above and to the right of the diagonal) of the square matrix formed by listing each group in the molecule along the row and column. The values for the interactions are shown in this format in Table 2-342.

**Example** Estimate the normal boiling point of di-isopropanolamine by using the Nannoolal method.

Structure:

Group contributions and values:

| Group            | $n_i$ | $C_i$    | Group total |
|------------------|-------|----------|-------------|
| —CH <sub>3</sub> | 2     | 177.3066 | 354.6132    |
| >C(c)<(e)        | 4     | 266.8769 | 1067.508    |
| —OH sec          | 2     | 390.2446 | 780.4892    |
| —NH—             | 1     | 223.0992 | 223.0992    |
| Corrections      |       |          |             |
| —OH::—OH         | 1/9   | 291.7985 | 32.42206    |
| —OH::—NH—        | 2/9   | 286.9698 | 63.77107    |
| Total            |       |          | 2521.902    |

Note that there are three interacting groups (—OH, —OH, —NH—) in the molecule which gives two —OH::—NH— interactions and one —OH::—OH interaction which are then divided by  $n$  ( $=9$ ) as in Eq. (2-16) to give the frequency.

Calculation using Eq. (2-15):

$$\frac{T_b}{K} = \frac{2521.902}{9^{0.6583} + 1.6868} + 84.3395 = 509.3 \quad T_b = 509.3 \text{ K}$$

The calculated value differs by -2.4 percent from the DIPPR<sup>®</sup> 801 recommended value of 521.9 K.

## Characterizing and Correlating Constants

**Acentric Factor** The acentric factor of a compound  $\omega$  is defined in terms of the reduced vapor pressure evaluated at a reduced temperature of 0.7 as

$$\omega = -\log P_r \Big|_{T_r=0.7} - 1.0000 \quad (2-17)$$

It is primarily used as a third parameter (beyond  $T_c$  and  $P_c$ ) in CS predictions as a measure of deviations from nonspherical molecular shape, hence the name, suggesting molecular interactions that are not between centers of molecules. However, as defined in Eq. (2-17),  $\omega$  also contains polarity information, and  $\omega$  increases slightly with increasing polarity for molecules of similar size and shape. The value of  $\omega$  is close to zero for small, spherically shaped, nonpolar molecules (argon, methane, etc.). It increases in value with larger deviations of molecular shape from spherical (longer chain lengths, less chain branching, etc.) and with increasing molecular polarity. When possible,  $\omega$  should be obtained from experimental vapor pressure correlations by using Eq. (2-17), but an accurate estimation of  $\omega$  can be made by using the critical constants and a single vapor pressure point by application of CS vapor pressure equations.

**Recommended Method** Ambrose-Walton modification of Lee-Kesler vapor pressure equations.

References: Ambrose, D., and J. Walton, *Pure & Appl. Chem.*, **61** (1989): 1395; Lee, B. I., and M. G. Kesler, *AIChE J.*, **21** (1975): 510.

Classification: Corresponding states.

Expected uncertainty: Generally within 5 percent.

Applicability: Most organic compounds.

Input data:  $T_c$ ,  $P_c$ , and a single vapor pressure point (e.g., the normal boiling point).

Description: See Eq. (2-25) for the equations used in this method. The vapor pressure equation is inverted to obtain the acentric factor from a single experimental vapor pressure point.

**Example** Calculate the acentric factor of chlorobenzene with a known value for  $T_b$ .

Input information: From the DIPPR<sup>®</sup> 801 database,  $T_b = 404.87 \text{ K}$ ,  $T_c = 632.35 \text{ K}$ , and  $P_c = 45.1911 \text{ bar}$ .

Calculation of auxiliary quantities:

$$T_{br} = \frac{T_b}{T_c} = \frac{404.87}{632.35} = 0.64 \quad \tau = 1 - 0.64 = 0.36$$

$$f^{(0)} = \frac{(-5.97616)(0.36) + (1.29874)(0.36)^{1.5} - (0.60394)(0.36)^{2.5} - (1.06841)(0.36)^5}{0.64}$$

$$= -3.0034$$

$$f^{(1)} = \frac{(-5.03365)(0.36) + (1.11505)(0.36)^{1.5} - (5.41217)(0.36)^{2.5} - (7.46628)(0.36)^5}{0.64}$$

$$= -3.1788$$

## 2-474 PHYSICAL AND CHEMICAL DATA

TABLE 2-341 Group Contributions for the Nannoolal\* Method for Normal Boiling Point

Table-specific nomenclature: (e) = connected to N, O, F, Cl; (ne) = not connected to N, O, F, Cl; (r) = in a ring; (c) = in a chain; (a) = aromatic, not necessarily carbon; (Ca) = aromatic carbon; b = any nonhydrogen atom

| 130         | ((C=)(C)C—CC3)                               | carbon with four carbon neighbors and one double-bonded carbon neighbor                             | 25.8348   |
| 131         | C2C—CC2                                      | carbon with four carbon neighbors, two on each side   | 35.8330   |
| 132         | C3C—CC2                                      | carbon with five carbon neighbors   | 51.9098   |
| 133         | C3C—CC3                                      | carbon with six carbon neighbors  | 111.8372  |

 \*Nannoolal, Y., et al., *Fluid Phase Equilib.* **226** (2004): 45.

$$f^{(2)} = \frac{(-0.64771)(0.36) + (2.41539)(0.36)^{1.5} - (4.26979)(0.36)^{2.5} + (3.25259)(0.36)^5}{0.64}$$

$$= -0.037$$

Calculation using Eq. (2-25) at the normal boiling point:

$$\ln \frac{1.01325}{45.1911} = -3.798 = f^{(0)} + \omega f^{(1)} + \omega f^{(2)} = 3.0034 + 3.1788\omega + 0.037\omega^2$$

$$\omega = 0.249$$

The value obtained from the Ambrose-Walton-Lee-Kesler method compares favorably with the value of 0.2499 recommended in the DIPPR® 801 database (obtained from the vapor pressure correlation).

**Radius of Gyration** The radius of gyration  $R_g$  is a measure of the mass distribution about the center of mass of a molecule. Radius  $R_g$  increases with molecular size. It is useful in CS applications to separate molecular size and shape effects from polar effects. It is defined in terms of the principal moments of inertia of a molecule ( $A$ ,  $B$ , and  $C$ ) as

$$R_g = \sqrt{\frac{(AB)^{1/2}N_A}{M}} \quad (2-18)$$

for planar molecules and as

$$R_g = \sqrt{\frac{2\pi(ABC)^{1/2}N_A}{M}} \quad (2-19)$$

\*Nannoolal, Y., et al., *Fluid Phase Equilib.*, **226** (2004): 45.

for nonplanar molecules. Radii of gyration can be calculated from these defining equations and principal moments of inertia obtained from spectral data or from computational chemistry software.

**Recommended Method** Principal moments of inertia.

*Classification:* Computational chemistry.

*Expected uncertainty:* Less than 5 percent.

*Applicability:* All molecules.

*Input data:* *M* and molecular structure.

*Description:* Computational chemistry software is used to optimize the geometry of the molecule and obtain the principal moments of inertia to be used in Eqs. (2-18) and (2-19).

**Example** Calculate the radius of gyration for hydrazine.

*Input information:* From the DIPPR<sup>®</sup> 801 database, *M* = 32.0452 kg/kmol. The structure of hydrazine is

*Calculation of the principal moments of inertia:* Optimizing hydrazine with HF/6-31G model chemistry gives the following principal moments of inertia:

$$A = 12.24050 \text{ amu} \cdot \text{Bohr}^2 \quad B = 72.41081 \text{ amu} \cdot \text{Bohr}^2$$

$$C = 79.16893 \text{ amu} \cdot \text{Bohr}^2$$

*Conversion from atomic units to SI gives*

$$A = (12.24050 \text{ amu} \cdot \text{Bohr}^2) \left( \frac{5.29177 \times 10^{-11} \text{ m}}{\text{Bohr}} \right)^2 \left( \frac{1.66054 \times 10^{-27} \text{ kg}}{\text{amu}} \right) \\ = 5.692 \times 10^{-47} \text{ kg} \cdot \text{m}^2$$

$$B = (72.41081 \text{ amu} \cdot \text{Bohr}^2) \left( \frac{4.65010^{-48} \text{ kg} \cdot \text{m}^2}{\text{amu} \cdot \text{Bohr}^2} \right) = 3.367 \times 10^{-46} \text{ kg} \cdot \text{m}^2$$

$$C = (79.16893 \text{ amu} \cdot \text{Bohr}^2) \left( \frac{4.65010^{-48} \text{ kg} \cdot \text{m}^2}{\text{amu} \cdot \text{Bohr}^2} \right) = 3.681 \times 10^{-46} \text{ kg} \cdot \text{m}^2$$

*Calculation using Eq. (2-19):*

$$(\text{ABC})^{1/3} = [(5.692 \times 10^{-47})(3.367 \times 10^{-46})(3.681 \times 10^{-46})]^{1/3} \text{ kg} \cdot \text{m}^2 \\ = 1.918 \times 10^{-46} \text{ kg} \cdot \text{m}^2$$

$$R_g = \sqrt{\frac{2\pi(1.918 \times 10^{-46} \text{ kg}\cdot\text{m}^2)(6.022 \cdot 10^{26} \text{ kmol}^{-1})}{32.0452 \text{ kg/kmol}}} = 1.505 \times 10^{-10} \text{ m}$$

This is 3.8 percent below the DIPPR® 801 database value of  $1.564 \times 10^{-10}$  m which was obtained from spectral principal moments of inertia.

**Dipole Moment** The dipole moment of a molecule is the first moment of the electric charge density expansion. All normal paraffins have a value of zero. Charge separation within the molecule due to electronegativity differences between bonded atoms increases the dipole moment. Computational chemistry software uses the electron density distribution of the optimized molecule to calculate dipole moments.

**Recommended Method** Electron density distribution.

**Classification:** Computational chemistry.

**Expected uncertainty:** Uncertainty varies depending upon the model chemistry chosen, but it can be as large as 60 percent.

**Applicability:** All molecules.

**Input data:** Molecular structure.

**Example** Calculate the dipole moment for methanol.

*Draw structure and optimize molecule using computational chemistry software:* The dipole moment obtained from a geometry optimized with the HF/6-31G model chemistry for methanol is 2.288 D. This value is 35 percent larger than the experimental gas-phase value of 1.700 D in the DIPPR® 801 database.

## VAPOR PRESSURE

**Liquids** Vapor pressure is the most important of the basic thermodynamic properties of fluids. It is the pressure of equilibrium, coexisting liquid and vapor phases at a specified temperature. The vapor pressure curve is a monotonic function of temperature from its minimum value (the triple point pressure) at the triple point temperature  $T_t$  to its maximum value (the critical pressure) at  $T_c$ .

Liquid vapor pressure data over a limited temperature range can be correlated with the Antoine [Antoine, C, *C.R.*, **107** (1888): 681, 836] equation

$$\ln \frac{P^*}{\text{Pa}} = A - \frac{B}{T/\text{K} + C} \quad (2-20)$$

Data from the triple point to the critical point can be correlated with either a modified form of the Wagner equation [Wagner, W., "A New Correlation Method for Thermodynamic Data Applied to the Vapor-Pressure Curve of Argon, Nitrogen, and Water," J.T.R. Watson (trans. and ed.), IUPAC Thermodynamic Tables Project Centre, London, 1977; Ambrose, D., *J. Chem. Thermodyn.*, **18** (1986): 45; Ambrose, D., and N. B. Ghiasse, *J. Chem. Thermodyn.*, **19** (1987): 903, 911]

$$\ln P_r^* = \frac{a\tau + b\tau^{1.5} + c\tau^{2.5} + d\tau^5}{1 - \tau} \quad \text{where } \tau \equiv 1 - T_r \quad (2-21)$$

or the Riedel [Riedel, L., *Chem. Ing. Tech.*, **26** (1954): 679] equation

$$\ln \frac{P^*}{\text{Pa}} = A + \frac{B}{T/\text{K}} + C \ln \frac{T}{\text{K}} + D \left( \frac{T}{\text{K}} \right)^E \quad (2-22)$$

Generally,  $E$  in Eq. (2-22) is assigned a value of 6, but values of 2 or 1 have also been used, particularly when correlating low-temperature data. While the Wagner equation can be used to correlate most fluids over the whole liquid range, a fifth term is often required for alcohols [Poling, B. E., *Fluid Phase Equil.*, **116** (1996): 102]:

$$\ln P_r^* = \frac{a\tau + b\tau^{1.5} + c\tau^{2.5} + d\tau^5 + e\tau^6}{1 - \tau} \quad (\text{for alcohols}) \quad (2-23)$$

Correlation of experimental data within a few tenths of a percent over the entire fluid range can usually be obtained with either the Wagner or Riedel equations.

Two prediction methods are recommended for liquid vapor pressure. The first method is based on the Riedel equation; the second is a CS method. Both methods require  $T_c$  and  $P_c$  as input, but these can

be estimated by the methods shown earlier if experimental values are unavailable.

**Recommended Method 1** Riedel method.

**Reference:** Riedel, L., *Chem. Ing. Tech.*, **26** (1954): 679

**Classification:** Empirical extension of theory and corresponding states.

**Expected uncertainty:** Varies strongly depending upon relative  $T$ , but 1 percent or less above  $T_b$  is typical with uncertainties of 5 to 30 percent near the triple point.

**Applicability:** Most organic compounds.

**Input data:**  $T_b$ ,  $T_c$ ,  $P_c$ .

**Description:** Equation (2-22) in reduced form

$$\ln P_r = A + \frac{B}{T_r} + C \ln T_r + DT_r^6 \quad (2-24)$$

Constants for this equation are determined from the following set of relationships:

$$\psi = -35 + \frac{36}{T_{br}} + 42 \ln T_{br} - T_{br}^6 \quad \alpha_c = \frac{3.758K\psi + \ln(P_c/1.01325 \text{ bar})}{K\psi - \ln T_{br}}$$

$$h = T_{br} \frac{\ln(P_c/1.01325 \text{ bar})}{1 - T_{br}} \quad D = K(\alpha_c - 3.758)$$

$$C = \alpha_c - 42D \quad B = -36D \quad A = 35D$$

Values of the constant  $K$  [Vetere, A., *Ind. Eng. Chem Res.*, **30** (1991): 2487]:

| Class                       | Value                 |
|-----------------------------|-----------------------|
| Acids                       | $K = -0.120 + 0.025h$ |
| Alcohols                    | $K = 0.373 - 0.030h$  |
| All other organic compounds | $K = 0.0838$          |

**Example** Estimate the vapor pressure of chlorobenzene at 50 K intervals from 300 to 600 K.

**Input information:** From the DIPPR® 801 database,  $T_b = 404.87$  K,  $T_c = 632.35$  K, and  $P_c = 45.1911$  bar.

**Auxiliary Quantities:**

$$K = 0.0838 \quad T_{br} = 404.87/632.35 = 0.640$$

$$\psi = -35 + \frac{36}{0.640} + 42 \ln 0.640 - (0.640)^6 = 2.431$$

$$\alpha_c = \frac{(3.758)(0.0838)(2.431) + \ln(45.191/1.01325)}{(0.0838)(2.431) - \ln(0.640)} = 7.0248$$

$$D = (0.0838)(7.0248 - 3.758) = 0.2738 \quad C = 7.0248 - (42)(0.2738) = -4.4729$$

$$B = -(36)(0.2738) = -9.8552 \quad A = -(35)(0.2738) = 9.5814$$

**Calculation using Eq. (2-24) at each  $T$  (detailed calculation shown for  $T = 500$  K):**

$$T_r = 500/632.35 = 0.7907$$

$$\ln P_r = 9.5814 - \frac{9.8552}{0.7907} - 4.4729 \ln 0.7907 + (0.2738)(0.7907)^6 = -1.7651$$

$$P_r = \exp(-1.7651) = 0.1712 \quad P = P_r P_c = (0.1712)(45.1911 \text{ bar}) = 7.74 \text{ bar}$$

| $T/\text{K}$ | $T_r$  | $\ln P_r$ | $P/\text{bar}$ | $P_{\text{DIPPR}}/\text{bar}$ | % Error |
|--------------|--------|-----------|----------------|-------------------------------|---------|
| 300          | 0.4744 | -7.8532   | 0.0176         | 0.0175                        | 0.3     |
| 350          | 0.5535 | -5.5704   | 0.172          | 0.172                         | 0.1     |
| 400          | 0.6326 | -3.9323   | 0.886          | 0.880                         | 0.6     |
| 450          | 0.7116 | -2.7101   | 3.01           | 2.98                          | 0.9     |
| 500          | 0.7907 | -1.7651   | 7.74           | 7.67                          | 0.9     |
| 550          | 0.8698 | -1.0067   | 16.51          | 16.39                         | 0.8     |
| 600          | 0.9488 | -0.3705   | 31.20          | 31.11                         | 0.3     |

**Recommended Method 2** Ambrose-Walton method.

**References:** Ambrose, D., and J. Walton, *Pure & Appl. Chem.*, **61** (1989): 1395; Lee, B. I., and M. G. Kesler, *AIChE J.*, **21** (1975): 510.

*Classification:* Corresponding states.

*Expected uncertainty:* Varies strongly with relative  $T$ , but less than 1 percent is typical above  $T_b$  if the acentric factor is known.

*Applicability:* Most organic compounds.

*Input data:*  $T_b$ ,  $T_c$ ,  $P_c$ , and  $\omega$ .

*Description:* The acentric factor is used to linearly interpolate within the simple-fluid and deviation terms for the  $\ln P^*$  values of the reference fluids, which themselves have been correlated with the Wagner vapor pressure equation.

$$\ln P_r^* = f^{(0)} + \omega f^{(1)} + \omega^2 f^{(2)}$$

$$\begin{aligned} f^{(0)} &= \frac{-5.97616\tau + 1.29874\tau^{1.5} - 0.60394\tau^{2.5} - 1.06841\tau^5}{1 - \tau} \\ f^{(1)} &= \frac{-5.03365\tau + 1.11505\tau^{1.5} - 5.41217\tau^{2.5} - 7.46628\tau^5}{1 - \tau} \\ f^{(2)} &= \frac{-0.64771\tau + 2.41539\tau^{1.5} - 4.26979\tau^{2.5} + 3.25259\tau^5}{1 - \tau} \end{aligned} \quad (2-25)$$

where  $\tau = 1 - T_r$ .

**Example** Repeat the calculation of the liquid vapor pressure of chlorobenzene at 50 K intervals from 300 to 600 K.

*Input information:* From the DIPPR® 801 database,  $T_c = 632.35$  K,  $P_c = 45.1911$  bar, and  $\omega = 0.249857$ .

*Auxiliary quantities:*

$$T_r = 500/632.35 = 0.7907 \quad \tau = 1 - 0.7907 = 0.2093$$

*Simple-fluid and deviation vapor pressure terms at each  $T$  (shown for  $T = 500$  K):*

$$\begin{aligned} f^{(0)} &= \frac{(-5.97616)(0.2093) + (1.29874)(0.2093)^{1.5} - (0.60394)(0.2093)^{2.5} - (1.06841)(0.2093)^5}{0.7907} = -1.4405 \\ f^{(1)} &= \frac{(-5.03365)(0.2093) + (1.11505)(0.2093)^{1.5} - (5.41217)(0.2093)^{2.5} - (7.46628)(0.2093)^5}{0.7907} = -1.3383 \\ f^{(2)} &= \frac{(-0.64771)(0.2093) + (2.41539)(0.2093)^{1.5} - (4.26979)(0.2093)^{2.5} + (3.25259)(0.2093)^5}{0.7907} = 0.0145 \end{aligned}$$

*Calculation using Eq. (2-25):*

$$\begin{aligned} \ln P_r^* &= -1.4405 + (0.249857)(-1.3383) + (0.249857)^2(0.0145) = -1.774 \\ P^* &= (45.1911 \text{ bar})[\exp(-1.774)] = 7.667 \text{ bar} \end{aligned}$$

| $T$ | $\tau$ | $f^{(0)}$ | $f^{(1)}$ | $f^{(2)}$ | $\ln P_r^*$ | $P^*/\text{bar}$ | $P^*_{\text{DIPPR}}/\text{bar}$ | % Error |

**Solids** Below the triple point, the pressure at which the solid and vapor phases of a pure component are in equilibrium at any given temperature is the vapor pressure of the solid. It is a monotonic function of temperature with a maximum at the triple point. Solid vapor pressures can be correlated with the same equations used for liquids. Estimation of solid vapor pressure can be made from the integrated form of the Clausius-Clapeyron equation

$$\ln \frac{P^*}{P_t^*} = \frac{\Delta H_{\text{sub}}}{RT_t} \left( 1 - \frac{T_t}{T} \right) \quad (2-26)$$

where  $T_t$  = triple point temperature

$P_t^*$  = triple point pressure

$\Delta H_{\text{sub}}$  = enthalpy of sublimation

The liquid and solid vapor pressures are identical at the triple point. A good vapor pressure correlation that is valid at the triple point may be used to obtain the triple point pressure. Estimating solid vapor pressures by using Eq. (2-26) generally requires an estimation of  $\Delta H_{\text{sub}}$ , and so the illustrative example is combined with the example on enthalpy of sublimation in the section on latent enthalpy.

## THERMAL PROPERTIES

**Enthalpy of Formation** The standard enthalpy (heat) of formation is the enthalpy change upon formation of 1 mol of the compound in its standard state from its constituent elements in their standard states. Two different standard enthalpies of formation are commonly defined based on the chosen standard state. The standard state enthalpy of formation  $\Delta H_f^\circ$  uses the naturally occurring phase at 298.15 K and 1 bar as the standard state; the ideal gas standard enthalpy (heat) of formation  $\Delta H_f^\circ$  uses the compound in the ideal gas state at 298.15 K and 1 bar as the standard state. In both cases, the standard state for the elements is their naturally occurring state of aggregation at 298.15 K and 1 atm. Sources for data include DIPPR®, TRC, SWS, JANAF, and Daubert, T. E., and R. P. Danner, *Technical Data Book—Petroleum Refining*, 5th ed., American Petroleum Institute, Washington, extant 1994. The Domalski-Hearing method is the most accurate general method for estimating either  $\Delta H_f^\circ$  or  $\Delta H_f^\circ$  if the appropriate GC values are available, but a CC method is also as accurate for estimating  $\Delta H_f^\circ$  if an isodesmic reaction can be formulated and used. The Domalski-Hearing method also applies to entropies, and the entropy predictive equations are listed in this section for convenience because they are equivalent in form to the enthalpy equations. However, discussion and illustration of the estimation methods for entropy are delayed to the next subsection.

**Recommended Method** Domalski-Hearing method.

*Reference:* Domalski, E. S., and E. D. Hearing, *J. Phys. Chem. Ref. Data*, **22** (1993): 805.

*Classification:* Group contributions.

*Expected uncertainty:* 3 percent.

*Applicability:* Organic compounds for which group contributions have been regressed.

*Input data:* Molecular structure.

*Description:* GC values from Table 2-343 are directly additive for both enthalpy of formation and absolute third-law entropies:

$$\frac{\Delta H_f^\circ}{\text{kJ/mol}} = \sum_{i=1}^N n_i (\Delta H_f^\circ)_i \quad \frac{S^\circ}{\text{J}\cdot\text{mol}^{-1}\text{K}^{-1}} = \sum_{i=1}^N n_i (S^\circ)_i \quad (2-27)$$

where  $(\Delta H_f^\circ)_i$  = enthalpy of formation GC value from Table 2-343 and  $(S^\circ)_i$  = entropy GC value from Table 2-343.

Group values in Table 2-343 are defined by the central, nonhydrogen group and the atoms bonded to that group. Thus, C—(2H)(2C) represents a C atom to which 2 H and 2 C atoms are bonded. For example, propane (CH<sub>3</sub>—CH<sub>2</sub>—CH<sub>3</sub>) is composed of three groups: two C—(3H)(C) and one C—(2H)(2C).

**Example** Estimate the standard and ideal gas enthalpies of formation of *o*-toluidine.

*Input information:* The melting point (256.8 K) and boiling point (473.49 K) given for *o*-toluidine in the DIPPR® 801 database bracket 298.15 K, and so the standard state phase at 298.15 K and 1 bar must be liquid.

*Structure:*

TABLE 2-343 Domalski-Hearing\* Group Contribution Values for Standard State Thermal Properties

This table is a partial listing of GC values available from the original Domalski-Hearing tables. Table-specific nomenclature: Cd = carbon with double bond; Ct = carbon with triple bond; Cb = carbon in benzene ring; Ca = allenic carbon; corr = correction term; Cbf = fused benzene ring; N<sub>A</sub> = azo nitrogen; N<sub>I</sub> = imino nitrogen.

## 2-480 PHYSICAL AND CHEMICAL DATA

TABLE 2-343 Domalski-Hearing\* Group Contribution Values for Standard State Thermal Properties (Continued)

This table is a partial listing of GC values available from the original Domalski-Hearing tables. Table-specific nomenclature: Cd = carbon with double bond; Ct = carbon with triple bond; Cb = carbon in benzene ring; Ca = allenic carbon; corr = correction term; Cbf = fused benzene ring;  $N_A$  = azo nitrogen;  $N_I$  = imino nitrogen.

| Group                              | $\Delta H_f^\circ$ | $S^\circ$ | $\Delta H_f^\circ$ liq. | $S^\circ$ liq. | $\Delta H_f^\circ$ solid | $S^\circ$ solid |
|------------------------------------|--------------------|-----------|-------------------------|----------------|--------------------------|-----------------|

TABLE 2-343 Domalski-Hearing\* Group Contribution Values for Standard State Thermal Properties (Continued)

This table is a partial listing of GC values available from the original Domalski-Hearing tables. Table-specific nomenclature: Cd = carbon with double bond; Ct = carbon with triple bond; Cb = carbon in benzene ring; Ca = allenic carbon; corr = correction term; Cbf = fused benzene ring; N<sub>A</sub> = azo nitrogen; N<sub>I</sub> = imino nitrogen.

| Group                                     | $\Delta H_f^\circ$ | S°      | $\Delta H_f^\circ$ liq. | S° liq. | $\Delta H_f^\circ$ solid | S° solid |
|---|--------------------|---------|-------------------------|---------|--------------------------|----------|

2-482 PHYSICAL AND CHEMICAL DATA

TABLE 2-343 Domalski-Hearing\* Group Contribution Values for Standard State Thermal Properties (Continued)

This table is a partial listing of GC values available from the original Domalski-Hearing tables. Table-specific nomenclature: Cd = carbon with double bond; Ct = carbon with triple bond; Cb = carbon in benzene ring; Ca = allenic carbon; corr = correction term; Cbf = fused benzene ring; N<sub>A</sub> = azo nitrogen; N<sub>I</sub> = imino nitrogen.

TABLE 2-343 Domalski-Hearing\* Group Contribution Values for Standard State Thermal Properties (Continued)

This table is a partial listing of GC values available from the original Domalski-Hearing tables. Table-specific nomenclature: Cd = carbon with double bond; Ct = carbon with triple bond; Cb = carbon in benzene ring; Ca = allenic carbon; corr = correction term; Cbf = fused benzene ring; N<sub>A</sub> = azo nitrogen; N<sub>I</sub> = imino nitrogen.

| Group                                   | $\Delta H_f^\circ$ | S°     | $\Delta H_f^\circ$ liq. | S° liq. | $\Delta H_f^\circ$ solid | S° solid |

TABLE 2-343 Domalski-Hearing\* Group Contribution Values for Standard State Thermal Properties (Concluded)

This table is a partial listing of GC values available from the original Domalski-Hearing tables. Table-specific nomenclature: Cd = carbon with double bond; Ct = carbon with triple bond; Cb = carbon in benzene ring; Ca = allenic carbon; corr = correction term; Cbf = fused benzene ring;  $N_A$  = azo nitrogen;  $N_I$  = imino nitrogen.

## Group contributions:

| Group       | $n_i$ | $\Delta H_f^\circ$ gas | $\Delta H_f^\circ$ liq. | $S^\circ$ gas | $S^\circ$ liq. |
|-------------|-------|------------------------|-------------------------|---------------|----------------|
| Cb—(H)(2Cb) | 4     | 13.81                  | 8.16                    | 48.31         | 28.87          |
| Cb—(C)(2Cb) | 1     | 23.64                  | 19.16                   | -35.61        | -19.50         |
| Cb—(N)(2Cb) | 1     | -1.30                  | 1.50                    | -43.53        | -24.43         |
| C—(3H)(C)   | 1     | -42.26                 | -47.61                  | 127.32        | 83.30          |
| N—(2H)(Cb)  | 1     | 19.25                  | -11.00                  | 126.90        | 71.71          |
| Total       |       | 54.57                  | -5.31                   | 368.32        | 226.56         |

Calculation from Eq. (2-27):

$$\frac{\Delta H_f^\circ}{\text{kJ/mol}} = 54.57 \quad \frac{\Delta H_f^\circ}{\text{kJ/mol}} = -5.31$$

$$\frac{S^\circ}{\text{J/(mol}\cdot\text{K)}} = 368.32 \quad \frac{S^\circ}{\text{J/(mol}\cdot\text{K)}} = 226.56$$

The recommended DIPPR® 801 standard enthalpies of formation are  $\Delta H_f^\circ = 53.20$  kJ/mol and  $\Delta H_f^\circ = -4.72$  kJ/mol; the estimated values are higher than the recommended values by 2.6 and 12.5 percent, respectively. The recommended DIPPR® 801 standard entropies are  $S^\circ = 355.5$  J/(mol·K) and  $S^\circ = 231.2$  J/(mol·K). The estimated values differ from these by 3.5 and -2.0 percent, respectively.

**Recommended Method** Isodesmic reaction.

Reference: Foresman, J. B., and A. Frisch, *Exploring Chemistry with Electronic Structure Methods*, 2d ed., Gaussian Inc., Pittsburgh, Pa., 1996.

Classification: Computational chemistry.

*Expected uncertainty:* 5 to 10 percent depending upon the level of theory and basis set size used.

*Applicability:* Compounds for which an isodesmic reaction can be formulated.

*Input data:* Experimental  $\Delta H_f^\circ$  values for all *other* participants in the isodesmic reaction.

*Description:* While *ab initio* calculations of absolute enthalpies are not currently as accurate as GC methods, *relative* enthalpies of molecules calculated with the same level of theory and basis set can be very accurate, as in the case of isodesmic reactions. An isodesmic reaction is one in which the number and type of bonds are preserved during the reaction. For example, the reaction of acetaldehyde with ethane to form acetone and methane

is isodesmic with 12 single bonds and 1 double bond in both reactants and products. To use this method, one devises an isodesmic reaction involving the compound for which  $\Delta H_f^\circ$  is to be determined and other compounds for which experimental  $\Delta H_f^\circ$  values are available. *Ab initio* calculations are performed on all the participating compounds, all at the same level of theory and basis set size, to obtain the enthalpy for each at 298.15 K. The enthalpy of reaction is then calculated from

$$\Delta H_{\text{rxn}} = \sum v_i H_i \quad (2-28)$$

where  $v_i$  = stoichiometric coefficient of  $i$  (+ for products, - for reactants). The enthalpy of reaction is also related to  $\Delta H_f^\circ$  by

$$\Delta H_{\text{rxn}} = \sum v_i (\Delta H_f^\circ)_i \quad (2-29)$$

With experimental values available for all  $\Delta H_f^\circ$  except the desired compound, its value can be back-calculated from Eq. (2-29).

**Example** Estimate the standard ideal gas enthalpy of formation of acetaldehyde.

*Input information:* The isodesmic reaction shown above will be used. The recommended  $\Delta H_f^\circ$  values from DIPPR® 801 for the other three compounds are

| Acetone        | Methane       | Ethane        |
|----------------|---------------|---------------|
| -215.70 kJ/mol | -74.52 kJ/mol | -83.82 kJ/mol |

*Ab initio calculations of enthalpy:* With structures optimized using HF/6-31G(d) model chemistry and energies calculated with B3LYP/6-311 + G(3df,2p), the following enthalpies are obtained (including the zero point energy):

| Acetone                     | Methane                     | Ethane                      | Acetaldehyde                |
|-----------------------------|-----------------------------|-----------------------------|-----------------------------|
| $-5.071 \times 10^5$ kJ/mol | $-1.063 \times 10^5$ kJ/mol | $-2.095 \times 10^5$ kJ/mol | $-4.039 \times 10^5$ kJ/mol |

Calculation using Eq. (2-28):

$$\Delta H_{\text{rxn}} = (-1.063 - 5.071 + 2.095 + 4.039) \times 10^5 \text{ kJ/mol} = -41.67 \text{ kJ/mol}$$

Calculation using Eq. (2-29):

$$\Delta H_{f,\text{acetaldehyde}}^\circ = \Delta H_{f,\text{acetone}}^\circ + \Delta H_{f,\text{methane}}^\circ - \Delta H_{f,\text{ethane}}^\circ - \Delta H_{\text{rxn}}$$

$$\Delta H_{f,\text{acetaldehyde}}^\circ = (-215.70 - 74.52 + 83.82 + 41.67) \frac{\text{kJ}}{\text{mol}} = -164.73 \frac{\text{kJ}}{\text{mol}}$$

The estimated value is 1.0 percent above the DIPPR® 801 recommended value of -166.40 kJ/mol.

**Entropy** Absolute or third-law entropies (relative to a perfectly ordered crystal at 0 K) of a compound in its standard state  $S^\circ$  or of an

ideal gas  $S^\circ$  at 298.15 K and 1 bar can be found in various literature sources (DIPPR, JANAF, TRC, SWS, and Daubert, T. E., and R. P. Danner, *Technical Data Book-Petroleum Refining*, 5th ed., American Petroleum Institute, Washington, extant 1994). Very good estimates for  $S^\circ$  or  $S^\circ$  can be obtained by using the Domalski-Hearing method. Excellent  $S^\circ$  values can also be obtained from statistical mechanics by using experimental vibrational frequencies or values of the frequencies generated from computational chemistry.

The standard state  $\Delta S_f^\circ$  and standard ideal gas  $\Delta S_f^\circ$  entropies of formation at 298.15 K and 1 bar are related to the standard entropies by

$$\Delta S_f^\circ = S_{\text{compound}}^\circ - \sum_{i=1}^{n_A} v_i S_{\text{element},i}^\circ \quad \Delta S_f^\circ = S_{\text{compound}}^\circ - \sum_{i=1}^{n_A} v_i S_{\text{element},i}^\circ \quad (2-30)$$

where  $S_{\text{element},i}^\circ$  is the absolute entropy of element  $i$  in its standard state at 298.15 K and 1 bar.

**Recommended Method** Domalski-Hearing method.

*Reference:* Domalski, E. S., and E. D. Hearing, *J. Phys. Chem. Ref. Data*, **22** (1993): 805.

*Classification:* Group contributions.

*Expected uncertainty:* 3 percent.

*Applicability:* Organic compounds for which group contributions have been regressed.

*Input data:* Molecular structure.

*Description:* See description given under Enthalpy of Formation above.

**Example** Estimate the standard and ideal gas entropies of formation of *o*-toluidine.

*Standard state entropies:* Estimation of  $S^\circ$  and  $S^\circ$  using the Domalski-Hearing method was illustrated above in the Enthalpy of Formation section. The standard entropies of formation can be obtained from the values determined in that example.

*Formula:* C<sub>7</sub>H<sub>9</sub>N. The standard state entropies of the elements from the DIPPR® 801 database are as follows:

| Compound:  | N <sub>2</sub>       | H <sub>2</sub>       | C, graphite |
|--|----------------------|----------------------|-------------|
| $v_i$ :  | 1/2                  | 9/2                  | 7           |
| $S^\circ/[\text{J}(\text{kmol}\cdot\text{K})]$ : | $1.9151 \times 10^5$ | $1.3057 \times 10^5$ | 5740        |

Entropies of formation can be calculated from these values by using Eq. (2-30):

$$\Delta S_f^\circ = \left[ 0.22656 - \left( \frac{1}{2} \right) (1.9151) - \left( \frac{9}{2} \right) (1.3057) - (7)(0.0574) \right] \frac{10^5 \text{ J}}{\text{kmol}\cdot\text{K}}$$

$$= -7.008 \cdot 10^5 \frac{\text{J}}{\text{kmol}\cdot\text{K}}$$

$$\Delta S_f^\circ = \left[ 0.36832 - \left( \frac{1}{2} \right) (1.9151) - \left( \frac{9}{2} \right) (1.3057) - (7)(0.0574) \right] \frac{10^5 \text{ J}}{\text{kmol}\cdot\text{K}}$$

$$= -6.867 \cdot 10^5 \frac{\text{J}}{\text{kmol}\cdot\text{K}}$$

**Recommended Method** Statistical mechanics.

*Classification:* Theory and computational chemistry.

*Expected uncertainty:* 0.2 percent if vibrational frequencies (or their characteristic temperatures) are experimentally available; uncertainty depends upon model chemistry if frequencies are determined from computational chemistry, but generally within about 5 percent.

*Applicability:* Ideal gases.

*Input data:*  $M$ ;  $\sigma$  (external symmetry number); characteristic rotational temperature(s) ( $\Theta_A$  for linear molecules;  $\Theta_A$ ,  $\Theta_B$ , and  $\Theta_C$  for nonlinear molecules); and  $3n_A - 6 + \delta$  characteristic vibrational temperatures  $\Theta_j$ .

*Description:* For harmonic frequencies, the rigorous temperature dependence of  $S^\circ$  is given by

$$\frac{S^\circ}{R} = \frac{3}{2} \ln \left( 6175 \frac{M}{\text{kg/kmol}} \right) + \frac{S_r}{R} + \sum_{j=1}^{3n_A - 6 + \delta} \left[ \left( \frac{\Theta_j}{T} \right) (e^{\Theta_j/T} - 1)^{-1} - \ln (1 - e^{-\Theta_j/T}) \right] \quad (2-31)$$

where  $\delta = \begin{cases} 0 & \text{nonlinear} \\ 1 & \text{linear} \end{cases}$

$$\frac{S_r}{R} = \begin{cases} \ln \left[ \frac{1}{\sigma} \left( \frac{\pi T^3 e^3}{\Theta_A \Theta_B \Theta_C} \right)^{1/2} \right] & \text{nonlinear} \\ \ln \left[ \left( \frac{T e}{\sigma \Theta_A} \right)^{1/2} \right] & \text{linear} \end{cases}$$

$$T = 298.15 \text{ K}$$

**Example** Calculate  $S^\circ$  for ammonia.

Structure:  $\text{NH}_3$ .

**Input data:**  $M = 17 \text{ kg/kmol}$ . McQuarrie [McQuarrie, D. A., *Statistical Mechanics*, Harper & Row, New York, 1976] gives the following  $3m - 6 + \delta = 12 - 6 + 0 = 6$  characteristic vibrational temperatures (K): 1360, 2330, 2330, 4800, 4880, 4880. The characteristic rotational temperatures given by McQuarrie are  $\Theta_A = 13.6 \text{ K}$ ,  $\Theta_B = 13.6 \text{ K}$ , and  $\Theta_C = 8.92 \text{ K}$ . For  $\text{NH}_3$ ,  $\sigma = 3$ .

**Vibrational contribution:** The table below shows a spreadsheet calculation of the vibrational terms inside the summation sign in Eq. (2-31).

| $\Theta_j/\text{K}$ | $\Theta_j/T$ | $S_{\text{vib}}$ |
|---------------------|--------------|------------------|
| 1207.91             | 4.051        | 0.08929          |

| Sum                 |              | 0.1186           |

**Rotational contribution:**

$$\frac{S_r}{R} = \ln \left\{ \frac{1}{3} \left[ \frac{(298.15 \text{ K})^3 \pi c^3}{(13.6 \text{ K})(13.6 \text{ K})(8.92 \text{ K})} \right]^{1/2} \right\} = 5.81593$$

**Calculation using Eq. (2-31):**

$$\frac{S_{298}^\circ}{R} = \frac{3}{2} \ln(6175.17) + 5.81593 + 0.1186 = 23.277 \quad \Delta H_{\text{res}} = \sum \nu_i (\Delta H_f^\circ)_i$$

$$S_{298}^\circ = 1.935 \times 10^5 \frac{\text{J}}{\text{kmol} \cdot \text{K}}$$

The calculated value differs from the DIPPR® 801 recommended value of  $1.9266 \times 10^5 \text{ J/(kmol} \cdot \text{K)}$  by 0.5 percent.

**Gibbs' Energy of Formation** The standard Gibbs energy of formation is the Gibbs energy change upon formation of 1 mol of the compound in its standard state from its constituent elements in their standard states. The standard state Gibbs energy of formation  $\Delta G_f^\circ$  uses the naturally occurring phase at 298.15 K and 1 bar as the standard state, while the ideal gas Gibbs energy of formation  $\Delta G_f^{\circ\text{ig}}$  uses the compound in the ideal gas state at 298.15 K and 1 bar as the standard state. In both cases, the standard state for the elements is their naturally occurring state of aggregation at 298.15 K and 1 atm. Sources for data include DIPPR, TRC, JANAF, and Daubert and Danner, (Daubert, T. E., and R. P. Danner *Technical Data Book—Petroleum Refining*, 5th ed., American Petroleum Institute, Washington, extant 1994). The Gibbs energies of formation are related to the corresponding enthalpies and entropies of formation by

$$\Delta G_f^\circ = \Delta H_f^\circ - T \Delta S_f^\circ \quad \text{and} \quad \Delta G_f^{\circ\text{ig}} = \Delta H_f^{\circ\text{ig}} - T \Delta S_f^{\circ\text{ig}} \quad (2-32)$$

and predicted values of  $\Delta G_f^\circ$  and  $\Delta G_f^{\circ\text{ig}}$  are obtained from Eq. (2-32) by estimating the enthalpies and entropies of formation as shown above.

## LATENT ENTHALPY

**Enthalpy of Vaporization** The enthalpy (heat) of vaporization  $\Delta H_v$  is the difference between the molar enthalpies of the saturated

vapor and saturated liquid at a temperature between the triple point and critical point (at the corresponding vapor pressure). Variable  $\Delta H_v$  is related to the vapor pressure  $P^\circ$  by the thermodynamically exact Clapeyron equation

$$\Delta H_v = -R \Delta Z_v \frac{d \ln P^\circ}{d(1/T)} = RT^2 \Delta Z_v \frac{d \ln P^\circ}{dT} \quad (2-33)$$

where  $\Delta Z_v = Z_C - Z_L$   
 $Z_C = Z$  of saturated vapor  
 $Z_L = Z$  of saturated liquid

Experimental heats of vaporization can be effectively correlated with

$$\Delta H_v = A(1 - T_r)^{B+CT_r+DT_r^2+ET_r^3} \quad (2-34)$$

A simple method for obtaining  $\Delta H_v$  at one temperature from a known value at a reference temperature, say, at the normal boiling point, is to truncate Eq. (2-34) after the  $B$  term, set  $B = 0.38$ , and take a ratio of the  $\Delta H_v$  values at the two conditions to give the Watson [Thek, R. E., and L. I. Stiel, *AIChE J.*, **12** (1966): 599; 13(1967): 626] correlation

$$\Delta H_v = \Delta H_{v,\text{ref}} \left( \frac{1 - T_r}{1 - T_{r,\text{ref}}} \right)^{0.38} \quad (2-35)$$

If an accurate correlation for  $P^\circ$  and accurate values for  $Z_C$  and  $Z_L$  are available, Eq. (2-33) is the preferred method for obtaining enthalpies of vaporization. Otherwise, the CS methods shown below should be used.

**Recommended Method 1** Vapor pressure correlation.

**Classification:** Extension of theory.

**Expected uncertainty:** Varies significantly with temperature and with the quality and temperature range of the vapor pressure data used in the correlation.

**Applicability:** Organic compounds for which group contributions have been regressed.

**Input data:** Correlations for  $P^\circ$ ,  $Z_C$ , and  $Z_L$ . If  $T_r < 0.8$ , then  $Z_C$  can be set to 1.

**Description:** An expression for  $\Delta H_v$  can be obtained from Eq. (2-33) by using an appropriate vapor pressure correlation. If one differentiates the Riedel vapor pressure correlation, Eq. (2-22), in accordance with Eq. (2-33), one obtains the heat of vaporization as

$$\Delta H_v = R \Delta Z_v (-B + CT + DET^{E+1}) \quad (2-36)$$

The  $Z_C$  and  $Z_L$  values can be evaluated by using the methods given in the subsection on densities below.

**Example** Calculate  $\Delta H_v$  for anisole at 452 K.

**Input data:** The vapor pressure coefficients in the DIPPR® 801 database, based on Eq. (2-22), are

$$A = 128.06 \quad B = -9307.7 \quad C = -16.693 \quad D = 0.014919 \quad E = 1$$

The vapor pressure at 452 K is

$$\ln \frac{P_r}{\text{Pa}} = 128.06 - \frac{9307.7}{452} - 16.693 \ln 452 + 0.014919(452)^1 = 12.155$$

$$P_r = \exp(12.155) \cdot \text{Pa} = 1.901 \times 10^5 \text{ Pa}$$

**Determine  $\Delta Z$ :** Required data from the DIPPR® 801 database for this calculation are  $T_c = 645.6 \text{ K}$ ,  $P_c = 4.25 \text{ MPa}$ , and  $\omega = 0.35017$ . These values are used to determine the reduced conditions and the values of  $Z_C$  and  $Z_L$  from the Lee-Kesler corresponding states method as discussed in the subsection on density.

$$T_r = \frac{452}{645.6} = 0.7 \quad P_r = \frac{0.1901}{4.25} = 0.045$$

Interpolation of the  $P_r$  values in Tables 2-351 and 2-352 at a  $T_r$  of 0.7 gives

$$Z_C^{(0)} = 0.9904 + \frac{0.045 - 0.010}{0.050 - 0.010} (0.9504 - 0.9904) = 0.9554$$

$$Z_C^{(1)} = -0.0064 + \frac{0.045 - 0.010}{0.050 - 0.010} (-0.0507 + 0.0064) = -0.0452$$

$$Z_C = Z_C^{(0)} + \omega Z_C^{(1)} = 0.9554 + (0.35017)(-0.0452) = 0.94$$

At this low pressure,  $Z_L$  is very small compared to  $Z_C$  and may be neglected; so

$$\Delta Z_V = Z_C - Z_L = 0.94$$

Calculation using Eq. (2-36):

$$\begin{aligned} \Delta H_v &= \left( 8.314 \frac{\text{J}}{\text{mol}\cdot\text{K}} \right) (0.94) [9307.7 - (16.693)(452) + (0.014919)(1)(452)^2] \\ &= 37.59 \frac{\text{kJ}}{\text{mol}\cdot\text{K}} \end{aligned}$$

This value is 0.2 percent higher than the value of 37.51 kJ/(mol·K) obtained from the DIPPR® 801 database.

**Recommended Method 2** Corresponding states correlation.

Reference: PGL5, p. 7.18.

Classification: Corresponding states.

Expected uncertainty: Less than about 6 percent.

Applicability: Organic compounds.

Input data:  $T_c$ ,  $P_c$ , and  $\omega$ .

Description: The following correlation is used:

$$\frac{\Delta H_v}{RT_c} = 7.08\tau^{0.354} + 10.95\omega\tau^{0.456} \quad \text{where } \tau = 1 - T_r \quad (2-37)$$

**Example** Repeat the above calculation for anisole's  $\Delta H_v$  at 452 K.

Input data:  $T_c = 645.6$  K,  $P_c = 4.25$  MPa, and  $\omega = 0.35017$ .

Auxiliary quantities: From the previous example, the reduced temperature is

$$T_r = 0.7 \quad \tau = 1 - 0.7 = 0.3$$

Calculation using Eq. (2-37):

$$\frac{\Delta H_v}{RT_c} = 7.08(0.3)^{0.354} + 10.95(0.35017)(0.3)^{0.456} = 6.838$$

$$\Delta H_v = (6.838) \left( 8.314 \frac{\text{J}}{\text{mol}\cdot\text{K}} \right) (645.6 \text{ K}) = 36.70 \frac{\text{kJ}}{\text{mol}\cdot\text{K}}$$

This value is 2.2 percent below the DIPPR® 801 recommended value of 37.51 kJ/(mol·K).

**Recommended Method 3** Vetere method for  $\Delta H_v$  at  $T_b$ .

Reference: Vetere, A., *Fluid Phase Equilib.*, **106** (1995): 1.

Classification: Corresponding states.

Expected uncertainty: About 4 percent.

Applicability: Valid only at the normal boiling point.

Input data:  $T_c$ ,  $P_c$ , and  $T_b$ .

Description: The following correlation is used:

$$\frac{\Delta H_v}{RT_b} = \frac{\tau_b^{0.38} \left[ \ln(P_c/\text{bar}) - 0.513 + \frac{0.5066 \cdot \text{bar}}{P_c T_b^2} \right]}{\tau_b + F(1 - \tau_b^{0.38}) \ln T_{br}} \quad (2-38)$$

where  $\tau_b = 1 - T_{br}$

For most compounds,  $F = 1$ ; compounds that dimerize (e.g.,  $\text{SO}_2$ ,  $\text{NO}$ ,  $\text{NO}_2$ ) and alcohols with more than two C atoms are assigned  $F = 1.05$ .

**Example** Calculate  $\Delta H_v$  at the normal boiling point for acetaldehyde.

Input data: Recommended values from the DIPPR® 801 database are  $T_c = 466.0$  K,  $P_c = 5.55$  MPa, and  $T_b = 294.0$  K.

Auxiliary quantities: From the previous example, the reduced temperature is

$$T_{br} = \frac{294}{466} = 0.631 \quad \tau_b = 1 - T_{br} = 0.369 \quad F = 1$$

Calculation using Eq. (2-38):

$$\frac{\Delta H_v}{RT_b} = \frac{(0.369)^{0.38} \left[ \ln 55.5 - 0.513 + \frac{0.5066/(55.5)(0.631)^2}{(0.369) + [1 - (0.369)^{0.38}] \ln 0.631} \right]}{(0.369) + [1 - (0.369)^{0.38}] \ln 0.631} = 10.785$$

$$\Delta H_v = (10.785) \left( 8.314 \frac{\text{J}}{\text{mol}\cdot\text{K}} \right) (294 \text{ K}) = 26.36 \frac{\text{kJ}}{\text{mol}\cdot\text{K}}$$

This value is 2.4 percent above the DIPPR® 801 recommended value of 25.73 kJ/(mol·K).

**Enthalpy of Fusion** The enthalpy (heat) of fusion  $\Delta H_{\text{fus}}$  is the difference between the molar enthalpies of the equilibrium liquid and solid at the melting temperature and 1.0 atm pressure. There is no generally applicable, high-accuracy estimation method for  $\Delta H_{\text{fus}}$ , but the GC method of Chickos can be used to obtain approximate results if the melting temperature is known.

**Recommended Method** Chickos method.

Reference: Chickos, J. S., et al., *J. Org. Chem.*, **56** (1991): 927.

Classification: QSPR and group contributions.

Expected uncertainty: Considerable variation but generally less than 50 percent.

Applicability: Only valid at the melting temperature. The method is based on the  $\Delta S_{\text{fus}}$  between a solid at 0 K and the liquid at the  $T_m$  so no solid-solid transitions are taken into account. Values of  $\Delta H_{\text{fus}}$  will be overestimated if there are solid-solid transitions for the actual material.

Input data:  $T_m$  and molecular structure.

Description:

$$\frac{\Delta H_{\text{fus}}}{\text{J/mol}} = \frac{\Delta S_{\text{fus}}}{\text{J/(mol}\cdot\text{K)}} \left( \frac{T_m}{\text{K}} \right) = (T_m/\text{K})(a + b) \quad (2-39)$$

$$a = \begin{cases} 0 & \text{no nonaromatic rings} \\ 35.19N_R + 4.289(N_{CR} - 3N_R) & \text{nonaromatic rings} \end{cases} \quad (2-40)$$

$$b = \sum_{i=1}^{n_g} N_{g_i} \Delta s_i + \sum_{j=1}^{n_s} N_{s_j} C_{s_j} \Delta s_j + \sum_{k=1}^{n_f} N_{f_k} C_{t_k} \Delta s_k \quad (2-41)$$

where  $N_{g_i}$  = number of C—H groups of type  $i$  bonded to other carbon atoms

$n_g$  = number of different nonring or aromatic C—H groups bonded to other carbon atoms

$N_{s_j}$  = number of C—H groups of type  $j$  bonded to at least one functional group or atom

$n_s$  = number of different nonring or aromatic C—H groups bonded to at least one functional group or atom

$N_{f_k}$  = number of functional groups of type  $k$

$n_f$  = number of different functional groups or atoms

$i$  = total number of functional groups or atoms with the exception that F atoms count as one regardless of number of occurrences

$C_{s_j}$  = value from Table 2-344 for C—H group  $j$  bonded to at least one functional group or atom

$C_{t_k}$  = value from Table 2-345 for functional group  $k$

$N_R$  = number of nonaromatic rings

$N_{CR}$  = number of  $-\text{CH}_2-$  groups in nonaromatic ring(s) required to form cyclic paraffin of same ring size(s)

$\Delta s_i$  = contribution from Table 2-344 for group  $i$

$\Delta s_k$  = contribution from Table 2-345 for group  $k$

TABLE 2-344 C<sub>s</sub> (C—H) Group Values for Chickos Estimation\* of ΔH<sub>fus</sub>

| Group             | Description     | C <sub>s</sub> | Δ <sub>s</sub> | Group                                  | Description                               | C <sub>s</sub> | Δ <sub>s</sub> |

$$T_m = 158.38 \text{ K} \quad \text{from DIPPR}^{\circ} \text{ 801 database}$$

$$\Delta H_{\text{fus}} = (T_m/K)(a + b) \text{ J/mol} = (158.38)(0 + 58.51) \text{ J/mol} = 9.27 \text{ kJ/mol}$$

This value is 5 percent higher than the DIPPR<sup>®</sup> 801 recommended value of 8.86 kJ/mol.

**Enthalpy of Sublimation** The enthalpy (heat) of sublimation ΔH<sub>sub</sub> is the difference between the molar enthalpies of the equilibrium vapor and solid along the sublimation curve below the triple point. The effects of pressure on ΔH<sub>fus</sub> and melting temperature are very small so that *T<sub>i</sub>* and the normal melting point are nearly equal and

$$\Delta H_{\text{sub}}(T_i) = \Delta H_v(T_i) + \Delta H_{\text{fus}}(T_i) \quad (2-42)$$

Equation (2-42) can be used to estimate ΔH<sub>sub</sub> at the triple point if ΔH<sub>v</sub> is accurately known at *T<sub>i</sub>*. Because ΔH<sub>v</sub> is usually obtained from Eq. (2-33), ΔH<sub>v</sub>(*T*) correlations may be less accurate near *T<sub>i</sub>* where *P*<sup>°</sup>(*T<sub>i</sub>*) is very small and difficult to measure. In this case, it is better to estimate ΔH<sub>sub</sub> directly by using the following recommended

method. Although Eqs. (2-33) and (2-34) apply to  $T_i$ ,  $\Delta H_{\text{sub}}$  is only a weak function of temperature and can generally be taken as a constant from the triple point temperature down to the first solid-solid phase transition.

**Recommended Method** Goodman method.

*Reference:* Goodman, B., et al., *Int. J. Thermophys.* **25** (2004): 337.

*Classification:* QSPR and group contributions.

*Expected uncertainty:* 6 percent.

*Applicability:* Organic compounds for which group contributions have been regressed.

*Input data:* Molecular structure and radius of gyration  $R_G$ .

*Description:*

$$\frac{\Delta H_{\text{sub}}(T_i)}{R K} = 698.04 + 3.83798 \times 10^{12} \left( \frac{R_G}{\text{m}} \right) + \sum_{i=1}^N n_i a_i + \sum_{i=1}^N n_i^2 \beta_i + \sum_{i=1}^N \frac{n_i}{n_x} f_i \quad (2-43)$$

where  $a_i$  = GC values from Table 2-346

$\beta_i$  = nonlinear corrections for  $>\text{CH}_2$  and  $\text{Ar}-\text{CH} =$  groups

$f_i$  = halogen corrections

$n_x$  = total number of all halogen and hydrogen atoms attached to C and Si atoms

**Example** Calculate  $\Delta H_{\text{sub}}$  and the solid vapor pressure for 1,2,3-trichlorobenzene at 301.15 K.

*Structure:*

*Group contributions:*

| Linear groups |       |                  | Nonlinear and correction terms |       |           |          |
|---------------|-------|------------------|--------------------------------|-------|-----------|----------|
| Group         | $n_i$ | $a_i$            | Group                          | $n_i$ | $\beta_i$ | $f_i$    |
| Ar—CH=        | 3     | 626.7621         | Ar—CH=                         | 3     | -2.21614  |          |
| Ar >C=        | 3     | 348.8092         | —Cl                            | 3     |           | -1543.66 |
| —Cl           | 3     | 1243.445         | $n_x$                          | 6     |           |          |
|               |       | $\sum_i n_i a_i$ | 6657.049                       |       |           |          |

*Input data:* The value of  $R_G$  from the DIPPR® 801 database is  $4.455 \times 10^{-10}$  m. *Calculation using Eq. (2-43):*

$$\frac{\Delta H_{\text{sub}}(T_i)}{R K} = 698.04 + (3.83798 \times 10^{12})(4.455 \times 10^{-10}) + 6657.049 + (3^2)(-2.21614) + \left( \frac{3}{6} \right)(-1543.66)$$

$$\Delta H_{\text{sub}}(T_i) = (8273.134 \text{ K}) \left( 0.008314 \frac{\text{kJ}}{\text{mol}\cdot\text{K}} \right) = 68.78 \frac{\text{kJ}}{\text{mol}}$$

The estimated value is 5.6 percent above the DIPPR® 801 recommended value of 65.11 kJ/mol.

*Estimate the solid vapor pressure from Eq. (2-26):* The solid vapor pressure at 301.15 K can be calculated from Eq. (2-26) by using the estimated  $\Delta H_{\text{sub}}$ . Recommended values for  $T_i$  and  $P_i^*$  from the DIPPR® 801 database are 325.65 K and 182.957 Pa, respectively.

$$\ln \frac{P^*}{182.957 \text{ Pa}} = \frac{68.78 \text{ kJ/mol}}{[0.008314 \text{ kJ/(mol}\cdot\text{K)}](325.65 \text{ K})} \left( 1 - \frac{325.65}{301.15} \right) = -2.067$$

$$P^* = (182.957 \text{ Pa})[\exp(-2.067)] = 23.16 \text{ Pa}$$

The estimated value is 0.3 percent above the DIPPR® 801 recommended value of 23.09 Pa.

## HEAT CAPACITY

*Heat capacity*  $C_p$  is defined as the energy required to change the temperature of a unit mass (specific heat) or mole (molar heat capacity) of the material by one degree. Typical units are J/(kg·K).

**Gases** The heat capacity of a gas is related rigorously to the ideal gas heat capacity  $C_p^0$  by

$$C_p = C_p^0 - T \int_0^P \left( \frac{\partial^2 V}{\partial T^2} \right)_P dP \quad (2-44)$$

The second term, giving the deviation of the real fluid heat capacity from the ideal gas value, can be neglected at low to moderate pressures, or it can be calculated directly from an appropriate EoS.

Ideal gas heat capacities are available from several sources (DIPPR, JANAF, TRC, and SWS). Two common correlating equations for  $C_p^0$  are the Aly-Lee [Aly, F. A., and L. L. Lee, *Fluid Phase Equilib.*, **6**

\*Goodman, B., et al., *Int. J. Thermophys.*, **25** (2004): 337.

(1981): 169] equation

$$C_p^o = A_0 + A_1 \left[ \frac{A_2/T}{\sinh(A_2/T)} \right]^2 + A_3 \left[ \frac{A_4/T}{\cosh(A_4/T)} \right]^2 \quad (2-45)$$

and a polynomial form (generally fourth-order)

$$C_p^o = \sum_{i=0}^4 A_i T^i \quad (2-46)$$

Ideal gas heat capacities may also be estimated from several techniques, of which two of the most accurate and commonly used are recommended here.

**Recommended Method 1** Statistical mechanics.

*Reference:* Rowley, R. L., *Statistical Mechanics for Thermophysical Property Calculations*, Prentice-Hall, Englewood Cliffs, N.J., 1994.

*Classification:* Theory and computational chemistry.

*Expected uncertainty:* 0.2 percent if vibrational frequencies (or their characteristic temperatures) are experimentally available; accuracy depends upon model chemistry if frequencies are determined from computational chemistry, but generally within 3 percent.

*Applicability:* Ideal gases.

*Input data:*  $3n_A - 6 + \delta$  vibrational frequencies  $\nu_j$ , or the corresponding characteristic vibrational temperatures  $\Theta_j$ . The two are related by

$$\Theta_j = h\nu_j/k \quad (2-47)$$

where  $n_A$  = number of atoms in molecule and  $\delta = 1$  for linear molecules and 0 for nonlinear molecules.

*Description:* For harmonic frequencies, the rigorous temperature dependence of  $C_p^o$  is given by

$$\frac{C_p^o}{R} = \frac{8 - \delta}{2} + \sum_{j=1}^{3n_A - 6 + \delta} \left( \frac{\Theta_j}{T} \right)^2 \left[ \frac{e^{\Theta_j/T}}{(e^{\Theta_j/T} - 1)^2} \right] \quad \delta = \begin{cases} 0 & \text{nonlinear} \\ 1 & \text{linear} \end{cases} \quad (2-48)$$

**Example** Calculate the ideal gas heat capacity of ammonia at 300 K.

*Structure:*

*Input data:* McQuarrie (McQuarrie, D. A., *Statistical Mechanics*, Harper & Row, New York, 1976) gives the following  $3m - 6 + \delta = 12 - 6 + 0 = 6$  characteristic vibrational temperatures (K): 1360, 2330, 2330, 4800, 4880, and 4880. Alternatively, a computational chemistry package gives the following *scaled* frequencies for HF/6-31G+ model chemistry ( $10^{13}$  Hz): 3.24, 4.97, 4.97, 9.90, 10.26, and 10.26.

*Calculation:* The table on the left uses the experimental  $\Theta$  values to determine the individual terms in the summation of Eq. (2-48); the table on the right uses the scaled frequencies from computational chemistry software and Eq. (2-47) to obtain  $\Theta$  values and the individual terms in Eq. (2-48).

| Experimental frequencies |                   |        |
|--------------------------|-------------------|--------|
| $\Theta$ /K              | $\Theta$ /(300 K) | Term   |
| 1360                     | 4.533             | 0.2256 |
| 2330                     | 7.767             | 0.0256 |
| 2330                     | 7.767             | 0.0256 |
| 4800                     | 16.000            | 0.0000 |
| 4880                     | 16.267            | 0.0000 |
| 4880                     | 16.267            | 0.0000 |
| Sum                      |                   | 0.2769 |

*From experimental frequencies:*

$$C_p^o = \left( \frac{8}{2} + 0.2769 \right) R = (4.2769) \left( 8.3143 \frac{\text{J}}{\text{mol}\cdot\text{K}} \right) = 35.56 \frac{\text{J}}{\text{mol}\cdot\text{K}}$$

*From computational chemistry frequencies:*

$$C_p^o = \left( \frac{8}{2} + 0.197 \right) R = (4.197) \left( 8.3143 \frac{\text{J}}{\text{mol}\cdot\text{K}} \right) = 34.90 \frac{\text{J}}{\text{mol}\cdot\text{K}}$$

The value calculated from experimental frequencies is 0.1 percent lower than the DIPPR<sup>®</sup> 801 recommended value of 35.61 J/(mol·K); the value calculated from frequencies generated from computational chemistry software is 2.0 percent lower than the DIPPR<sup>®</sup> 801 value.

**Recommended Method 2** Benson method as implemented in CHETAH program.

*References:* Benson, S. W., et al., *Chem. Rev.*, **69** (1969): 279; CHETAH Version 8.0: *The ASTM Computer Program for Chemical Thermodynamic and Energy Release Evaluation (NIST Special Database 16)*.

*Classification:* Group contributions.

*Expected uncertainty:* 4 percent.

*Applicability:* Ideal gases of organic compounds.

*Input data:* Table 2-347 group values at the seven specified temperatures.

*Description:* Groups are summed at each individual temperature:

$$C_p^o = \sum_{i=1}^N n_i \cdot (C_p^o)_i \quad (2-49)$$

where  $n_i$  = number of occurrences of group  $i$  and  $(C_p^o)_i$  = individual group contribution. Either Eq. (2-45) or Eq. (2-46) can be used to interpolate between the discrete temperatures.

**Example** Calculate the ideal gas heat capacity of isoprene (2-methyl-1,3-butadiene) at 400 K.

*Structure:*

*Group identification and values:*

| Group                  | No. | Value, J/(mol·K) | Contribution, J/(mol·K) |
|------------------------|-----|------------------|-------------------------|
| =CH <sub>2</sub>       | 2   | 26.62            | 53.24                   |
| =C-(2C)                | 1   | 19.3             | 19.3                    |
| -CH <sub>2</sub> -(=C) | 1   | 32.82            | 32.82                   |
| =CH-(C)                | 1   | 21.05            | 21.05                   |
| Total                  |     |                  | 126.41                  |

The value of 126.4 J/(mol·K) is 3.1 percent below the DIPPR<sup>®</sup> 801 recommended value of 130.4 J/(mol·K).

**Liquids** Liquid heat capacity increases with increasing temperature, although a minimum occurs near the triple point for many compounds. Usually liquid heat capacity is correlated as a function of temperature with a polynomial equation. A cubic equation is usually adequate.

Estimation of liquid heat capacity can be done by using a number of methods [Ruzicka, V., and E. S. Domalski, *J. Phys. Chem. Ref. Data*, **22** (1993): 597, 619; Chueh, C. F., and A. C. Swanson, *Chem. Eng.*

NOTE: Empirical scaling factors have been developed for each model chemistry to help correct theoretical frequencies for anharmonic effects [Scott, A. P., and L. Radom, *J. Phys. Chem.*, **100** (1996): 16502].

| HF/6-31G + scaled frequencies |             |                   |        |

 \*Benson, S. W., et al., *Chem. Rev.*, **69** (1969): 279.

 †CHETAH Version 8.0: *The ASTM Computer Program for Chemical Thermodynamic and Energy Release Evaluation (NIST Special Database 16)*.

*Prog.*, **69**, 7 (1973): 83; Lee, B. I., and M. G. Kesler, *AIChE J.*, **21** (1975): 510; Tarakad, R. R., and R. P. Danner, *AIChE J.*, **23** (1977): 944] and thermodynamic differentiation. The most accurate and generally applicable method is that by Ruzicka and Domalski.

**Recommended Method** Ruzicka-Domalski.

*References:* Ruzicka, V., and E. S. Domalski, *J. Phys. Chem. Ref. Data*, **22** (1993): 597, 619.

*Classification:* Group contributions.

*Expected Uncertainty:* 4 percent.

*Applicability:* Organic compounds for which group values are available.

*Input data:* Molecular structure and Table 2-348 values.

*Description:* Groups are summed to find the temperature coefficients for a cubic polynomial correlation:

$$\frac{C_p}{R} = A + B\left(\frac{T}{100 \text{ K}}\right) + D\left(\frac{T}{100 \text{ K}}\right)^2 \quad (2-50)$$

$$A = \sum_{i=1}^N n_i a_i \quad B = \sum_{i=1}^N n_i b_i \quad D = \sum_{i=1}^N n_i d_i \quad (2-51)$$

where  $n_i$  = number of occurrences of group  $i$  and  $a_i$ ,  $b_i$ ,  $d_i$  = individual group contributions.

**Example** Estimate the liquid heat capacity for 2-methyl-2-propanol at 340 K.

*Structure:*

*Group contributions:*

| Group              | $n_i$ | $a_i$   | $b_i$    | $d_i$   |
|--------------------|-------|---------|----------|---------|
| C—(3C,O) (alcohol) | 1     | -44.690 | 31.769   | -4.8791 |
| O—(H)(C)           | 1     | 12.952  | -10.145  | 2.6261  |
| C—(3H)(C)          | 3     | 3.8452  | -0.33997 | 0.19489 |
| Sum                |       | -20.202 | 20.604   | -1.668  |

$$\begin{aligned} C_p &= \left(8.3143 \frac{\text{J}}{\text{mol}\cdot\text{K}}\right) \left[ -20.202 + 20.604 \left(\frac{340}{100}\right) - 1.668 \left(\frac{340}{100}\right)^2 \right] \\ &= 254.16 \frac{\text{J}}{\text{mol}\cdot\text{K}} \end{aligned}$$

This value is 0.7 percent higher than the DIPPR® 801 recommended value of 252.40 J/(mol·K).

**Solids** Solid heat capacity increases with increasing temperature and is proportional to  $T^3$  near absolute zero. The heat capacity at a solid-solid phase transition becomes large, and there can be a substantial dif-

ference in the heat capacity of the two equilibrium solid phases that exist on either side of the transition temperature. The heat capacity generally rises steeply with increasing temperature near the triple point.

For a quick estimation of solid heat capacity specifically at 298.15 K, the very simple modification of Kopp's rule [Kopp, H., *Ann. Chem. Pharm. (Liebig)*, **126** (1863): 362] by Hurst and Harrison [Hurst, J. E., and B. K. Harrison, *Chem. Eng. Comm.*, **112** (1992): 21] can be used. At other temperatures and to obtain the temperature dependence of the solid heat capacity, the method given below by Goodman et al. should be used.

**Recommended Method 1** Goodman method.

*Reference:* Goodman, B. T., et al., *J. Chem. Eng. Data*, **49** (2004): 24.

*Classification:* Group contributions.

*Expected uncertainty:* 10 percent.

*Applicability:* Organic compounds for which group values are available.

*Input data:* Molecular structure and Table 2-349 group values.

*Description:*

$$\frac{C_p}{\text{J}/(\text{mol}\cdot\text{K})} = \frac{A}{1000} \left(\frac{T}{\text{K}}\right)^{0.79267} \quad (2-52)$$

$$A = \exp\left(6.7796 + \sum_{i=1}^N n_i a_i + \sum_{i=1}^N n_i^2 \beta_i\right) \quad (2-53)$$

where  $n_i$  = number of occurrences of group  $i$

$a_i$  = individual group contribution

$\beta_i$  = nonlinear correction terms for chain and aromatic carbons

**Example** Estimate the solid heat capacity for *p*-cresol at 307.93 K.

*Structure:*

*Group contributions:*

| Group            | $n_i$ | $a_i$    | $\beta_i$ |
|------------------|-------|----------|-----------|
| —CH <sub>3</sub> | 1     | 0.20184  | 0         |
| Ar—CH=           | 4     | 0.082478 | -0.00033  |
| Ar >C=           | 2     | 0.012958 | 0         |
| —OH              | 1     | 0.10341  | 0         |

From Eq. (2-53):

$$A = \exp[6.7796 + 0.20184 + (4)(0.082478) + (2)(0.012958) + 0.10341 + (4)^2(-0.00033)] = 1694.9$$

TABLE 2-348 Liquid Heat Capacity Group Parameters for Ruzicka-Domalski Method\*

Table-specific nomenclature: Ct refers to a carbon atom with a triple bond; Cb refers to a carbon atom in benzene ring; =C refers to a carbon atom with a double bond; Cp refers to a carbon atom in a fused benzene ring; =C= refers to an allenic carbon atom.

\*Ruzicka, V., and E. S. Domalski, *J. Phys. Chem. Ref. Data*, **22** (1993): 597, 619.

From Eq. (2-52):

$$C_p = \frac{1694.9}{1000} (307.93)^{0.79267} \frac{\text{J}}{\text{mol}\cdot\text{K}} = 159.1 \frac{\text{J}}{\text{mol}\cdot\text{K}}$$

This value is 2.5 percent higher than the DIPPR® 801 recommended value of 155.2 J/(mol·K).

### Recommended Method 2 Modified Kopp's rule.

Reference: Kopp, H., *Ann. Chem. Pharm. (Liebig)*, **126** (1863): 362; Hurst, J. E., and B. K. Harrison, *Chem. Eng. Comm.*, **112** (1992): 21.

Classification: Group contributions.

Expected uncertainty: 10 percent.

Applicability: 298.15 K; organic compounds that are solids at 298.15 K.

Input data: Compound chemical formula and element contributions of Table 2-350.

Description:

$$\frac{C_p}{\text{J}/(\text{mol}\cdot\text{K})} = \sum_{E=1}^N n_E \Delta_E \quad (2-54)$$

where  $N$  = number of different elements in compound  
 $n_E$  = number of occurrences of element  $E$  in compound  
 $\Delta_E$  = contribution of element  $E$  from Table 2-350

**Example** Estimate the solid heat capacity at 298.15 K for dibenzothio-  
 phene.

Structure:  $\text{C}_{12}\text{H}_8\text{S}_2$ .

Group values from Table 2-350:

$$\Delta_C = 10.89 \quad \Delta_H = 7.56 \quad \Delta_S = 12.36$$

Calculation using Eq. (2-54):

$$C_p = (12)(10.89) + (8)(7.56) + (1)(12.36) = 203.52 \text{ J}/(\text{mol}\cdot\text{K})$$

This value is 2.5 percent higher than the DIPPR® 801 recommended value of 198.45 J/(mol·K).

**Mixtures** The heat capacity of liquid and vapor mixtures can be estimated as mole fraction averages of the pure-component values

$$C_{p,m} = \sum_{i=1}^C x_i C_{p,i} \quad (2-55)$$

This neglects the excess heat capacity, which if available can be added to the mole fraction average to improve the estimated value.

## DENSITY

*Density* is defined as the mass of a substance per unit volume. Density is given in kg/m<sup>3</sup> in SI units, but lb<sub>m</sub>/ft<sup>3</sup> and g/cm<sup>3</sup> are common AES and cgs units, respectively. Other commonly used forms of density include *molar density* (density divided by molecular weight) in kmol/m<sup>3</sup>, *relative density* (density relative to water at 15°C), and the older term *specific gravity* (density relative to water at 60°F). Often the inverse of *molar density*, *specific volume*, and the inverse of *molar density*, *molar volume*, are correlated and used to convey equivalent information.

**Gases** Gases/vapors are compressible and their densities are strong functions of both temperature and pressure. Equations of state (EoS) are commonly used to correlate molar densities or molar volumes. The most accurate EoS are those developed for specific fluids with parameters regressed from all available data for that fluid. Super EoS are available for some of the most industrially important gases and may contain 50 or more constants specific to that chemical. Different predictive methods may be used for gas densities depending upon the conditions:

1. At *very low densities* (high temperatures, generally above the critical, and very low pressures, generally below a few bar), the ideal gas EoS

$$Z \equiv \frac{PV}{RT} = 1 \quad (2-56)$$

may be applied.

2. At *moderate densities* (below 40 percent of the critical density), the virial equation truncated after the second virial coefficient

$$Z = 1 + \frac{B(T)}{V} \quad (2-57)$$

may be used. Second virial coefficients  $B(T)$  are available in the DIPPR® 801 database for many chemicals and can be estimated for others by using the Tsonopoulos method.

\*Kopp, H., *Ann. Chem. Pharm. (Liebig)*, **126** (1863): 362.†Hurst, J. E., and B. K. Harrison, *Chem. Eng. Comm.*, **112** (1992): 21.

$$B^{(1)} = 0.0637 + \frac{0.331}{T_r^2} - \frac{0.423}{T_r^3} - \frac{0.008}{T_r^6} \quad (2-60)$$

$$B^{(2)} = \frac{a}{T_r^6} - \frac{b}{T_r^8} \quad (2-61)$$

$$\mu_r = \left( \frac{\mu}{D} \right)^2 \left( \frac{P_c}{\text{bar}} \right) \left( \frac{T_c}{\text{K}} \right)^{-2} \quad (2-62)$$

where  $\mu$  = dipole moment. The values of  $a$  and  $b$  used in Eq. (2-61) depend upon the class of fluid, as given in the table below:

| Class   | $a$  | $b$                    |
|---|--|------------------------|
| Nonpolar fluids   | 0  | 0                      |
| Ketones, aldehydes, nitriles, ethers, esters, NH <sub>3</sub> , H <sub>2</sub> S, HCN | $-21.4\mu_r - 4.308 \times 10^{19}\mu_r^8$                   | 0                      |
| Monoalkylhalides, mercaptans, sulfides  | $-2.188 \times 10^{16}\mu_r^4 - 7.831 \times 10^{19}\mu_r^8$ | 0                      |
| 1-Alcohols except methanol  | 0.0878   | $0.00908 + 69.57\mu_r$ |
| Methanol  | 0.0878   | 0.0525                 |

**Example** Estimate the molar volume of ammonia at 430 K and 2.82 MPa.Input properties: Recommended values from the DIPPR® S01 database are  $T_c = 405.65$  K,  $P_c = 11.28$  MPa,  $\mu = 1.469$  D, and  $\omega = 0.252608$ .

Reduced conditions:

$$T_r = (430 \text{ K}) / (405.65 \text{ K}) = 1.06$$

$$P_r = (2.82 \text{ MPa}) / (11.28 \text{ MPa}) = 0.25$$

$$\mu_r = (1.469)^2 (112.8) / (405.65)^2 = 0.0014793$$

Second virial coefficient from Eqs. (2-59) to (2-61):

$$B^{(0)} = 0.1445 - 0.330/1.06 - 0.1385/(1.06)^2 - 0.0121/(1.06)^3$$

$$-0.000607/(1.06)^8 = -0.301$$

$$B^{(1)} = 0.0637 + 0.331/(1.06)^2 - 0.423/(1.06)^3 - 0.008/(1.06)^8 = -0.00189$$

$$a = (-21.4)(0.0014793) - (4.308 \times 10^{10})(0.0014793)^8 = -0.033$$

$$b = 0$$

$$B^{(2)} = (-0.033)/(1.06)^6 = -0.023$$

From Eq. (2-58):

$$BP_c/(RT_c) = -0.301 - (0.252608)(0.00189) - 0.023 = -0.324$$

$$B = (-0.324)[0.008314 \text{ m}^3 \cdot \text{MPa}/(\text{kmol} \cdot \text{K})](405.65 \text{ K})/(11.28 \text{ MPa}) \\ = -0.097 \text{ m}^3/\text{kmol}$$

Molar volume from Eq. (2-56):

$$V = \frac{RT}{P} \left( 1 + \frac{B}{V} \right) = \frac{(0.0083143 \frac{\text{m}^3 \cdot \text{MPa}}{\text{kmol} \cdot \text{K}})(430 \text{ K})}{2.82 \text{ MPa}} \left( 1 + \frac{-0.097 \frac{\text{m}^3}{\text{kmol}}}{V} \right) \\ = 1.162 \text{ m}^3/\text{kmol}$$

Note that the ideal gas value,  $1.268 \text{ m}^3/\text{kmol}$ , deviates by 9.1 percent from this more accurate value. The truncated virial EoS should be valid for this density since  $\rho = V^{-1} = 0.86 \text{ kmol}/\text{m}^3$  is much less than 40 percent of the critical density (the DIPPR<sup>®</sup> 801 recommended value for the critical density is  $13.8 \text{ kmol}/\text{m}^3$ ).

3. For higher gas densities, the Lee-Kesler method described below provides excellent predictions for nonpolar and slightly polar fluids. Extended four-parameter corresponding-states methods are available for polar and slightly associating compounds.

**Recommended Method** Lee-Kesler method.

Reference: Lee, B. I., and M. G. Kesler, *AIChE J.*, **21** (1975): 510.

Classification: Corresponding states.

Expected uncertainty: 1 percent except near the critical point where errors can be up to 30 percent.

Applicability: Nonpolar and moderately polar compounds. An extended Lee-Kesler method, not described here, may be used for polar and slightly associating compounds [Wilding, W. V., and R. L. Rowley, *Int. J. Thermophys.*, **8** (1986): 525].

Input data:  $T_c$ ,  $P_c$ ,  $\omega$ ,  $Z^{(0)}$ ,  $Z^{(1)}$ .

Description:

$$Z = Z^{(0)} + \omega Z^{(1)} \quad (2-63)$$

where  $Z$  = compressibility factor

$Z^{(0)}$  = compressibility factor of simple fluid obtained from Table 2-351.

$Z^{(1)}$  = deviation from simple fluid obtained from Table 2-352.

Analytical expressions for  $Z^{(0)}$  and  $Z^{(1)}$  can also be generated by using

$$Z^{(0)} = Z_0 \quad Z^{(1)} = \frac{Z_1 - Z_0}{0.3978} \quad (2-64)$$

where  $Z_0$  and  $Z_1$  are determined from

$$Z_i = \frac{P_r V_r}{T_r} = 1 + \frac{B}{V_r} + \frac{C}{V_r^2} + \frac{D}{V_r^3} + \frac{c_4}{T_r^3 V_r^2} \left( \beta + \frac{\gamma}{V_r^2} \right) \exp \left( \frac{-\gamma}{V_r^2} \right) \quad (2-65)$$

$$B = b_1 - \frac{b_2}{T_r} - \frac{b_3}{T_r^2} - \frac{b_4}{T_r^3}$$

$$C = c_1 - \frac{c_2}{T_r} + \frac{c_3}{T_r^2}$$

$$D = d_1 + \frac{d_2}{T_r}$$

as applied to the simple reference fluid and to the acentric reference fluid (*n*-octane), respectively. The constants for Eq. (2-65) for the two reference fluids are given in Table 2-353.

**Example** Estimate the molar volume of saturated decane vapor at 540.5 K. Input properties: Recommended values from the DIPPR<sup>®</sup> 801 database are  $T_c = 617.7 \text{ K}$ ,  $P_c = 2.11 \text{ MPa}$ ,  $P^s(540.5 \text{ K}) = 0.6799 \text{ MPa}$  (vapor pressure), and  $\omega = 0.492328$ .

Reduced conditions:

$$T_r = (540.5 \text{ K})/(617.7 \text{ K}) = 0.875$$

$$P_r = (0.6799 \text{ MPa})/(2.11 \text{ MPa}) = 0.322$$

LK compressibility factor: Since vapor phase values are needed, the appropriate values from Tables 2-351 and 2-352 that can be used to double-interpolate are

| $Z^{(0)}$            |        |          |
|----------------------|--------|----------|
| $T_r \backslash P_r$ | 0.2    | 0.4      |
| 0.85                 | 0.8810 | (0.7222) |
| 0.90                 | 0.9015 | 0.7800   |

| $Z^{(1)}$            |         |           |
|----------------------|---------|-----------|
| $T_r \backslash P_r$ | 0.2     | 0.4       |
| 0.85                 | -0.0715 | (-0.1503) |
| 0.90                 | -0.0442 | -0.1118   |

Double linear interpolation within these values gives  $Z^{(0)} = 0.8058$  and  $Z^{(1)} = -0.1025$ .

From Eq. (2-63):

$$Z = 0.8058 + (0.492328)(-0.1025) = 0.7553$$

Note: If the analytical form available in Eq. (2-65) is used, the following more accurate values are obtained:  $Z^{(0)} = 0.8131$ ,  $Z^{(1)} = -0.1067$ , and  $Z = 0.7606$ .

Molar volume:

$$V = \frac{ZRT}{P} = \frac{(0.7553) \left( 0.0083143 \frac{\text{m}^3 \cdot \text{MPa}}{\text{kmol} \cdot \text{K}} \right) (540.5 \text{ K})}{0.6799 \text{ MPa}} = 4.992 \frac{\text{m}^3}{\text{kmol}}$$

4. Cubic EoS can be used to obtain both vapor and liquid densities as an alternative method to those mentioned above.

**Recommended Method** Cubic EoS.

Classification: Empirical extension of theory.

Expected uncertainty: Varies depending upon compound and conditions, but a general expectation is perhaps 10 to 20 percent.

Applicability: Nonpolar and moderately polar compounds.

Input data:  $T_c$ ,  $P_c$ ,  $\omega$ .

Description: The more common cubic EoS can be written in the form

$$Z = \frac{V}{V-b} - \frac{V}{V^2 + \delta V + \epsilon} - \frac{a \alpha(T_r)}{RT} \quad (2-66)$$

where  $a$ ,  $b$ ,  $\delta$ , and  $\epsilon$  are constants that depend upon the model EoS chosen, as does the temperature dependence of the function  $\alpha(T_r)$ . Definitions of these constants and  $\alpha(T_r)$  for some of the more commonly used EoS models are shown in Table 2-354. The corresponding relations for many other EoS models in this same form are available [Soave, G., *Chem. Eng. Sci.*, **27** (1972): 1197]. The independent parameters  $a$  and  $b$  in these models can be regressed from experimental data to correlate densities or obtained from known critical constants to predict density data. In the latter case, the relationships between  $a$  and  $b$  and the critical constants shown in Table 2-354 were obtained from the critical point requirements

$$\left( \frac{\partial P}{\partial V} \right)_{T=T_c} = 0 = \left( \frac{\partial^2 P}{\partial V^2} \right)_{T=T_c} \quad (2-67)$$

**TABLE 2-351 Simple Fluid Compressibility Factors  $Z^{(0)}$** Values in parentheses are for the opposite phase and may be used to interpolate to or near the phase boundary [PGL4; Wilding, W. V., J. K. Johnson, and R. L. Rowley, *Int. J. Thermophys.*, **8**(1987):717].

| $\gamma$          | 0.060167               | 0.03754                  |

\*Lee, B. I., and M. G. Kesler, *AIChE J.*, **21** (1975): 510.

Of the cubic EoS given in Table 2-354, the Soave and Peng-Robinson are the most accurate, but there is no general rule for which EoS produces the best estimated volumes for specific fluids or conditions. The Peng-Robinson equation has been better tuned to liquid densities, while the Soave equation has been better tuned to vapor-liquid equilibrium and vapor densities. In solving the cubic equation for volume, a convenient initial guess to find the vapor root is the ideal gas value, while an initial value of  $1.05b$  is convenient to locate the liquid root.

**Example** Estimate the molar density of liquid and vapor saturated ammonia at 353.15 K, using the Soave and Peng-Robinson EoS.

*Required properties:* Recommended values in the DIPPR® 801 database are

$$T_c = 405.65 \text{ K} \quad P_c = 112.8 \text{ bar} \quad \omega = 0.252608$$

$$P^* (353.15 \text{ K}) = 41.352 \text{ bar (vapor pressure at 353.15 K)}$$

*EoS parameters (shown for Soave EoS):*

$$a = \frac{0.42748(RT_c)^2}{P_c} = \frac{0.42748 \left[ \left( 83.145 \frac{\text{bar}\cdot\text{cm}^3}{\text{mol}\cdot\text{K}} \right) (405.65 \text{ K}) \right]^2}{112.8 \text{ bar}}$$

$$= 4.311 \times 10^6 \frac{\text{cm}^6\cdot\text{bar}}{\text{mol}^2}$$

$$b = \frac{0.08664(RT_c)}{P_c} = \frac{0.08664 \left( 83.145 \frac{\text{bar}\cdot\text{cm}^3}{\text{mol}\cdot\text{K}} \right) (405.65 \text{ K})}{112.8 \text{ bar}}$$

$$= 25.906 \frac{\text{cm}^3}{\text{mol}}$$

$$T_r = (353.15 \text{ K}) / (405.65 \text{ K}) = 0.871$$

$$\alpha = [1 + [0.48 + (1.574)(0.252608) - (0.176)(0.252608)^2][1 - (0.871)^{0.5}]^2 = 1.119$$

Rearrange and solve Eq. (2-66) for  $V$ :

$$P = \frac{RT}{V-b} - \frac{a\alpha}{V(V+b)} \quad \text{or} \quad PV^3 - RTV^2 + (a\alpha - bRT - Pb^2)V - ab\alpha = 0$$

$$41.352 \left( \frac{V}{\text{m}^3/\text{mol}} \right)^3 - \left( 0.029 \frac{\text{m}^3}{\text{mol}} \right) \left( \frac{V}{\text{m}^3/\text{mol}} \right)^2 + \left( 4.037 \times 10^{-6} \frac{\text{m}^6}{\text{mol}^2} \right) \times \left( \frac{V}{\text{m}^3/\text{mol}} \right) - 1.25 \times 10^{-10} = 0$$

*Vapor root (initial guess of  $V = 7.1 \times 10^{-7} \text{ m}^3/\text{mol}$  from ideal gas equation):*

$$V_{\text{vap}} = 5.395 \times 10^{-4} \text{ m}^3/\text{mol} \quad \text{and} \quad \rho_{\text{vap}} = 1/V_{\text{vap}} = 1.854 \text{ kmol/m}^3$$

*Liquid root (initial guess of  $V = 2.72 \times 10^{-5} \text{ m}^3/\text{mol}$  from 1.05b):*

$$V_{\text{liq}} = 4.441 \times 10^{-5} \text{ m}^3/\text{mol} \quad \text{and} \quad \rho_{\text{liq}} = 1/V_{\text{liq}} = 22.516 \text{ kmol/m}^3$$

*The corresponding values and equation for the Peng-Robinson EoS are*

$$a = 4.611 \times 10^6 \text{ cm}^6\cdot\text{bar/mol}^2 \quad b = 23.262 \text{ cm}^3/\text{mol}$$

$$\alpha = 1.103$$

$$P = \frac{RT}{V-b} - \frac{a\alpha}{V^2 + 2bV - b^2}$$

or

$$PV^3 + (bP - RT)V^2 + (a\alpha - 2bRT - 3Pb^2)V + (bP^3 + RTb^2 - ab\alpha) = 0$$

$$41.352 \left( \frac{V}{\text{m}^3/\text{mol}} \right)^3 - \left( 0.0284 \frac{\text{m}^3}{\text{mol}} \right) \left( \frac{V}{\text{m}^3/\text{mol}} \right)^2 + \left( 3.651 \times 10^{-6} \frac{\text{m}^6}{\text{mol}^2} \right) \times \left( \frac{V}{\text{m}^3/\text{mol}} \right) - 1.018 \times 10^{-10} = 0$$

$$V_{\text{vap}} = 5.286 \times 10^{-4} \text{ m}^3/\text{mol} \quad \text{and} \quad \rho_{\text{vap}} = 1.892 \text{ kmol/m}^3$$

$$V_{\text{liq}} = 3.914 \times 10^{-5} \text{ m}^3/\text{mol} \quad \text{and} \quad \rho_{\text{liq}} = 25.55 \text{ kmol/m}^3$$

The liquid density calculated from the Soave EoS is 24.2 percent below the DIPPR® 801 recommended value of 29.69 kmol/m<sup>3</sup>, while that calculated from the Peng-Robinson EoS is 13.9 percent below the recommended value.

**TABLE 2-354 Relationships for Eq. (2-66) for Common Cubic EoS**

| EoS            | $\delta$ | $\epsilon$ | $\alpha(T_r)$   | $aP_c/(RT_c)^2$ | $bP_c/(RT_c)$ |
|----------------|----------|------------|---|-----------------|---------------|
| van der Waals* | 0        | 0          | 1   | 0.42188         | 0.125         |
| Rellich-Kwong† | 0        | 0          | $T_r^{-0.5}$  | 0.42748         | 0.08664       |
| Soave‡         | $b$      | 0          | $[1 + (0.48 + 1.574\omega - 0.176\omega^2)(1 - T_r^{0.5})]^2$       | 0.42748         | 0.08664       |
| Peng-Robinson§ | $2b$     | $-b^2$     | $[1 + (0.37464 + 1.54226\omega - 0.2699\omega^2)(1 - T_r^{0.5})]^2$ | 0.45724         | 0.0778        |

†Redlich, O., and J. N. S. Kwong, *Chem. Rev.*, **44** (1949): 233.

‡Soave, G., *Chem. Eng. Sci.*, **27** (1972): 1197.

§Peng, D. Y., and D. B. Robinson, *Ind. Eng. Chem. Fundam.*, **15** (1976): 59.

**Liquids** For most liquids, the saturated molar liquid density  $\rho$  can be effectively correlated with

$$\rho = \frac{A}{B^{[1+(1-T/C)^D]}} \quad (2-68)$$

adapted from the Rackett prediction equation [Rackett, H. G., *J. Chem. Eng. Data*, **15** (1970): 514]. The regression constants  $A$ ,  $B$ , and  $D$  are determined from the nonlinear regression of available data, while  $C$  is usually taken as the critical temperature. The liquid density decreases approximately linearly from the triple point to the normal boiling point and then nonlinearly to the critical density (the reciprocal of the critical volume). A few compounds such as water cannot be fit with this equation over the entire range of temperature.

The recommended method for estimation of saturated liquid density for pure organic compounds is the Rackett prediction method.

**Recommended Method** Rackett method.

*Reference:* Rackett, H. G., *J. Chem. Eng. Data*, **15** (1970): 514.

*Classification:* Corresponding states.

*Expected uncertainty:* 8 percent as purely predictive equation; 2 percent if  $Z_{RA}$  (see Description below) or some liquid density data are available.

*Applicability:* Saturated liquid densities of organic compounds.

*Input data:*  $T_c$ ,  $P_c$ , and  $Z_c$  (or, equivalently,  $V_c$ ).

*Description:* A predictive form of the equation is given by

$$\frac{1}{\rho} = V = \left( \frac{RT_c}{P_c} \right) Z_c^q \quad \text{where } q = 1.0 + (1.0 - T_r)^{2.7} \quad (2-69)$$

A modification of the Rackett method by Spencer and Danner [Spencer, C. F., and R. P. Danner, *J. Chem. Eng. Data*, **17** (1972): 236] replaces  $Z_c$  with an adjustable parameter  $Z_{RA}$

$$\frac{1}{\rho} = V = \left( \frac{RT_c}{P_c} \right) Z_{RA}^q \quad (2-70)$$

to provide better estimations of liquid density away from the critical point [Eq. (2-70) gives the correct critical density only when  $Z_{RA} = Z_c$ ]. An alternative to this modification when several liquid density data points are available is to replace the 2/7 power in  $q$  of Eq. (2-69) with an adjustable parameter. This generally provides good agreement with the experimental values and permits accurate extrapolation of the densities all the way to the critical point.

**Example** Estimate the saturated liquid density of acetonitrile at 376.69 K.

*Required properties:* The recommended values from the DIPPR® 801 database are

$$T_c = 545.5 \text{ K} \quad P_c = 4.83 \text{ MPa} \quad Z_c = 0.184$$

*Calculate supporting quantities:*

$$T_r = (376.69 \text{ K}) / (545.5 \text{ K}) = 0.691$$

$$q = 1 + (1 - 0.691)^{2.7} = 1.715$$

*Calculate saturated liquid density from Eq. (2-69):*

$$\rho = \left[ \frac{4.83 \times 10^6 \text{ Pa}}{\left( 8.314 \frac{\text{Pa}\cdot\text{m}^3}{\text{mol}\cdot\text{K}} \right) (545.5 \text{ K})} \right] (0.184)^{-1.715} = 19.42 \frac{\text{kmol}}{\text{m}^3}$$

This estimated value is 16.1 percent above the DIPPR® 801 recommended value of 16.726 kmol/m<sup>3</sup>.

*Calculate  $\rho_{\text{sat}}$  from Eq. (2-70):* Kratzke [Kratzke, H., and S. Muller, *J. Chem. Thermo.*, **17** (1985): 151] reported an experimental density of 18.919 kmol/m<sup>3</sup> at 298.08 K. Use of this experimental value in Eq. (2-70) to calculate  $Z_{RA}$  gives

$$T_r = (298.08 \text{ K}) / (545.5 \text{ K}) = 0.546 \quad q = 1 + (1 - 0.546)^{2.7} = 1.798$$

$$Z_{RA} = \left[ \frac{4.83 \times 10^6 \text{ Pa}}{\left( 8.314 \frac{\text{Pa}\cdot\text{m}^3}{\text{mol}\cdot\text{K}} \right) (545.5 \text{ K}) \left( 18.919 \frac{\text{kmol}}{\text{m}^3} \right)} \right]^{1/1.798} = 0.202$$

$$\rho = \left[ \frac{4.83 \times 10^6 \text{ Pa}}{\left( 8.314 \frac{\text{Pa}\cdot\text{m}^3}{\text{mol}\cdot\text{K}} \right) (545.5 \text{ K})} \right] (0.202)^{-1.715} = 16.577 \frac{\text{kmol}}{\text{m}^3}$$

The value obtained by the modified Rackett method is 0.9 percent below the DIPPR® 801 recommended value. Note, however, that with  $Z_{RA} = 0.202$ , Eq. (2-70) gives  $\rho_c = 5.28$  kmol/m<sup>3</sup> as opposed to the DIPPR® 801 recommended value of 5.79 kmol/m<sup>3</sup>. If the power is regressed from the Kratzke density, one obtains  $q_1 = 0.452$  and  $\rho = 15.68$  kmol/m<sup>3</sup> (4 percent below the experimental value), while still retaining  $\rho_c = 5.79$  kmol/m<sup>3</sup>.

**Solids** Solid density data are sparse and usually available only within a narrow temperature range. For most solids, density decreases approximately linearly with increasing temperature. Prediction of solid densities is an inexact science, but reasonable correlation has been found between the density of the liquid phase at the triple point and the solid that is stable at the triple point conditions.

**Recommended Method** Goodman method.

*Reference:* Goodman, B. T., et al., *J. Chem. Eng. Data*, **49** (2004): 1512.

*Classification:* Empirical correlation.

*Expected uncertainty:* 6 percent.

*Applicability:* Organic compounds; applicable to the stable solid phase at the triple point temperature  $T_i$ , to either the next solid-phase transition temperature or to approximately  $0.3T_i$ .

*Input data:* Liquid density at the triple point.

*Description:* The density for the solid phase that is stable at the triple point has been correlated as a function of temperature and the liquid density at  $T_i$ :

$$\rho_s = \left( 1.28 - 0.16 \frac{T}{T_i} \right) \rho_L(T_i) \quad (2-71)$$

**Example** Estimate the density of solid naphthalene at 281.46 K.

*Required properties:* The recommended values from the DIPPR® 801 database for  $T_i$  and the liquid density at  $T_i$  are

$$T_i = 353.43 \text{ K} \quad \rho_L(T_i) = 7.6326 \text{ kmol/m}^3$$

*From Eq. (2-71):*

$$\rho_s = \left( 1.28 - 0.16 \frac{281.46 \text{ K}}{353.43 \text{ K}} \right) \left( 7.6326 \frac{\text{kmol}}{\text{m}^3} \right) = 8.797 \frac{\text{kmol}}{\text{m}^3}$$

The estimated value is 4.3 percent lower than the DIPPR® 801 recommended value of 9.1905 kmol/m<sup>3</sup>.

**Mixtures** Both liquid and vapor densities can be estimated using pure-component CS and EoS methods by treating the fluid as a pseudo-pure component with effective parameters calculated from the pure-component parameters and using ad hoc mixing rules.

To apply the Lee-Kesler CS method to mixtures, pseudo-pure fluid constants are required. One of the simplest set of mixing rules for these quantities is [Prausnitz, J. M., and R. D. Gunn, *AIChE J.*, **4** (1958): 430, 494; Joffe, J., *Ind. Eng. Chem. Fundam.*, **10** (1971): 532]:

$$\bar{T}_c = \sum_{i=1}^C x_i T_{c,i} \quad (2-72)$$

$$\bar{P}_c = \frac{\sum_{i=1}^C x_i Z_{c,i}}{\sum_{i=1}^C x_i V_{c,i}} \bar{R}\bar{T}_c \quad (2-73)$$

$$\bar{\omega} = \sum_{i=1}^C x_i \omega_i \quad (2-74)$$

The procedures are identical to those for pure components with the replacement of  $T_c$ ,  $P_c$ , and  $\omega$  with the effective mixture values calculated by using these equations.

To use a cubic EoS for a mixture, mixing rules are used to calculate effective mixture parameters in terms of the pure-component values. Although there are more complex mixing rules available that may improve prediction accuracy, the simplest forms are recommended here for their simplicity and reasonable accuracy without adjustable parameters:

$$\bar{b} = \sum_{i=1}^C x_i b_i \quad (2-75)$$

$$\bar{a}\bar{\alpha} = \left[ \sum_{i=1}^C x_i (a_i \alpha_i)^{1/2} \right]^2 \quad (2-76)$$

Mixture calculations are then identical to the pure-component calculations using these effective mixture parameters for the pure-component  $a\alpha$  and  $b$  values.

The actual mixture second virial coefficient  $B_m$  is related to the pure-component values by

$$B_m = \sum_{i=1}^C \sum_{j=1}^C x_i x_j B_{ij} \quad \text{where} \quad B_{ii} = B_i \quad (2-77)$$

This requires calculation of all possible binary pair interaction virials ( $B_{ij}$ ,  $i \neq j$ ) for the mixture. Again the pure-component methods can be used to provide estimates of these values by using the following combining rules:

$$T_{c,ij} = \sqrt{T_{c,i} T_{c,j}} \quad V_{c,ij} = \left( \frac{V_{c,i}^{1/3} + V_{c,j}^{1/3}}{2} \right)^3 \quad Z_{c,ij} = \frac{Z_{c,i} + Z_{c,j}}{2} \quad (2-78)$$

$$\omega_{ij} = \frac{\omega_i + \omega_j}{2} \quad P_{c,ij} = \frac{Z_{c,ij} \bar{R} T_{c,ij}}{V_{c,ij}} \quad (2-79)$$

These interaction parameters are used in place of the corresponding pure-component parameters to determine the  $B_{ij}$  values.

The modified Rackett method has also been extended to liquid mixtures [Spencer, C. F., and R. P. Danner, *J. Chem. Eng. Data*, **17** (1972): 236; Li, C. C., *Can. J. Chem. Eng.*, **19** (1971): 709]:

$$T_{c,ij} = \sqrt{T_{c,i} T_{c,j}} \quad \phi_i = \frac{x_i V_{c,i}}{\sum_{j=1}^C x_j V_{c,j}} \quad \bar{T}_c = \sum_{i=1}^C \sum_{j=1}^C \phi_i \phi_j T_{c,ij} \quad (2-80)$$

**Recommended Method** Spencer-Danner-Li mixing rules with Rackett equation.

**References:** Spencer, C. F., and R. P. Danner, *J. Chem. Eng. Data*, **17** (1972): 236; Li, C. C., *Can. J. Chem. Eng.*, **19** (1971): 709.

**Classification:** Corresponding states.

**Expected uncertainty:** About 7 percent on average; higher near the  $T_c$  of any of the components.

**Applicability:** Saturated (at the bubble point) liquid mixtures.

**Input data:**  $T_c$ ,  $V_c$ , and  $x_i$ .

**Description:** The predictive form of the equation is given by

$$\frac{1}{\rho} = V = R \left( \sum_{i=1}^C \frac{x_i T_{c,i}}{P_{c,i}} \right) \bar{Z}_{RA}^q \quad q = 1.0 + (1.0 - T_r)^{2/7} \quad (2-81)$$

where

$$\bar{Z}_{RA} = 0.29056 - 0.08775 \sum_{i=1}^C x_i \omega_i \quad \text{and} \quad T_r = \frac{T}{T_c} \quad (2-82)$$

**Example** Estimate the saturated liquid density of a liquid mixture of 50 mol % ethane(1) and 50 mol % *n*-decane(2) at 377.6 K.

**Required properties:** The recommended values from the DIPPR® 801 database for the required properties are as follows:

|        | $T_c$ /K | $V_c$ /(m <sup>3</sup> ·kmol <sup>-1</sup> ) | $P_c$ /bar | $\omega$ |
|--------|----------|--|------------|----------|
| Ethane | 305.32   | 0.1455                                       | 48.72      | 0.0995   |
| Decane | 617.7    | 0.617  | 21.1       | 0.4923   |

*Auxiliary quantities from Eq. (2-80):*

$$\phi_1 = \frac{(0.5)(0.1455)}{(0.5)(0.1455) + (0.5)(0.617)} = 0.191; \quad \phi_2 = 0.809$$

$$T_{c,12} = \sqrt{(305.32 \text{ K})(617.7 \text{ K})} = 434.3 \text{ K}$$

$$\begin{aligned} \frac{\bar{T}_c}{\text{K}} &= \phi_1^2 T_{c,1} + 2\phi_1 \phi_2 T_{c,12} + \phi_2^2 T_{c,2} \\ &= (0.191)^2 (305.32) + (2)(0.191)(0.809)(434.3) + (0.809)^2 (617.7) \end{aligned}$$

$$\bar{T}_c = 549.68 \text{ K}$$

*Calculations from Eqs. (2-81) and (2-82):*

$$T_r = (377.6 \text{ K}) / (549.68 \text{ K}) = 0.687$$

$$q = 1 + (1 - 0.687)^{2/7} = 1.718$$

$$\bar{Z}_{RA} = 0.29056 - 0.08775[(0.5)(0.0995) + (0.5)(0.4923)] = 0.2646$$

$$\begin{aligned} V &= \left( 0.08314 \frac{\text{m}^3 \cdot \text{bar}}{\text{K} \cdot \text{kmol}} \right) \left[ \frac{(0.5)(305.32 \text{ K})}{48.72 \text{ bar}} + \frac{(0.5)(617.7 \text{ K})}{21.1 \text{ bar}} \right] (0.2646)^{1.718} \\ &= 0.151 \frac{\text{m}^3}{\text{kmol}} \end{aligned}$$

The experimental value [Reamer, H. H., and B. H. Sage, *J. Chem. Eng. Data*, **7** (1962): 161] is 0.149 m<sup>3</sup>/kmol, and the error in the estimated value is 1.3 percent.

## VISCOSITY

*Viscosity* is defined as the shear stress per unit area at any point in a confined fluid, divided by the velocity gradient in the direction perpendicular to the direction of flow. The *absolute viscosity*  $\eta$  is the shear stress at a point, divided by the velocity gradient at that point. The SI unit of viscosity is Pa·s [1 kg/(m·s)], but the cgs unit of poise (P) [1 g/(cm·s)] is also commonly used. Because many common fluids have viscosities on the order of 0.01 P, the unit of centipoise (cP) is also frequently used (1 cP = 1 mPa·s). The *kinematic viscosity*  $\nu$  is defined as the ratio of the absolute viscosity to density at the same temperature and pressure. The SI unit for  $\nu$  is m<sup>2</sup>/s, but again cgs units are very common and  $\nu$  is often given in stokes (St) (1 cm<sup>2</sup>/s) or centistokes (cSt) (0.01 cm<sup>2</sup>/s).

**Gases** Experimental data for gases and vapors at low density are often correlated with

$$\eta^0 = \frac{AT^B}{1 + C/T + D/T^2} \quad (2-83)$$

Over smaller temperature ranges, parameters  $C$  and  $D$  may not be necessary as  $\ln \eta$  is often reasonably linear with  $\ln T$ . Care should be taken in extrapolating using Eq. (2-83) as there can be unintended mathematical poles where the denominator approaches zero.

Numerous methods have been developed for estimation of vapor viscosity. For nonpolar vapors, the Yoon-Thodos CS method works well, but for polar fluids the Reichenberg method is preferred. Both methods are illustrated below.

**Recommended Method** Yoon-Thodos method.

Reference: Yoon, P., and G. Thodos, *AIChE J.*, **16** (1970): 300.

Classification: Corresponding states.

Expected uncertainty: 5 percent.

Applicability: Nonpolar and slightly polar organic vapors.

Input data:  $T_c$ ,  $P_c$ , and  $M$ .

Description: The correlation for viscosity as a function of reduced temperature is

$$\frac{\eta^o}{\text{Pa}\cdot\text{s}} = \frac{46.1T_r^{0.618} - 20.4 \exp(-0.449T_r) + 19.4 \exp(-4.058T_r) + 1}{2.173424 \times 10^{11}(T_c/K)^{1/6}(M/\text{g}\cdot\text{mol})^{-1}(P_c/\text{Pa})^{-2/3}} \quad (2-84)$$

**Example** Estimate the low-pressure vapor viscosity of propane at 353 K.

Required constants: The DIPPR® 801 database recommends the following values:

$$T_c = 369.83 \text{ K} \quad P_c = 4.248 \text{ MPa} \quad M = 44.0956 \text{ g/mol}$$

Reduced temperature:

$$T_r = (353 \text{ K})/(369.83 \text{ K}) = 0.9545$$

Calculation using Eq. (2-84):

$$\frac{\eta^o}{\text{Pa}\cdot\text{s}} = \frac{(46.1)(0.9545)^{0.618} - 20.4 \exp[-0.449(0.9545)] + 19.4 \exp[-4.058(0.9545)] + 1}{(2.173424 \times 10^{11})(369.83)^{-1/2}(44.0956)^{-1/2}(4.248 \times 10^6)^{-2/3}} = 9.84 \times 10^{-6}$$

The estimated value is 1.5 percent higher than the DIPPR® 801 recommended value of  $9.70 \times 10^{-6}$  Pa·s.

**Recommended Method** Reichenberg method.

Reference: Reichenberg, D., *AIChE J.*, **21** (1975): 181.

Classification: Group contributions and corresponding states.

Expected uncertainty: 5 percent.

Applicability: Nonpolar and polar organic and inorganic vapors.

Input data:  $T_c$ ,  $P_c$ ,  $M$ ,  $\mu$ , and molecular structure.

Description: The temperature dependence of the viscosity is given by

$$\frac{\eta^o}{\text{Pa}\cdot\text{s}} = \frac{AT_r^2}{[1 + 0.36T_r(T_r - 1)]^{1/6}} \left[ \frac{1 + 270(\mu_r^*)^4}{T_r + 270(\mu_r^*)^4} \right] \quad (2-85)$$

where the parameter  $A$  is determined from group contributions and the modified reduced dipole  $\mu_r^*$  is found from

$$\mu_r^* = 52.46\mu_r \quad (2-86)$$

and Eq. (2.62).

For organic compounds,  $A$  is found from the group values  $C_i$ , listed in Table 2-355, using

$$A = 10^{-7} \frac{\left[ \frac{M}{(\text{kg}/\text{kmol})} \right]^{1/2} (T_c/K)}{\sum_{i=1}^N n_i C_i} \quad (2-87)$$

For inorganic gases,  $A$  is obtained from

$$A = 1.6104 \times 10^{-10} \left[ \left( \frac{M}{\text{g/mol}} \right)^{1/2} \left( \frac{P_c}{\text{Pa}} \right)^{2/3} \left( \frac{T_c}{\text{K}} \right)^{-1/6} \right] \quad (2-88)$$

TABLE 2-355 Reichenberg\* Group Contribution Values

| Group                 | $C_i$ | Group            | $C_i$ |
|-----------------------|-------|------------------|-------|
| —CH <sub>3</sub>      | 9.04  | —F               | 4.46  |

\*Reichenberg, D., *AIChE J.*, **21** (1975): 181.

**Example** Estimate the low-pressure vapor viscosity of ethyl acetate at 401.25 K.

Required constants: The DIPPR® 801 database recommends the following values:

$$M = 88.1051 \text{ g/mol} \quad T_c = 523.3 \text{ K} \quad P_c = 3.88 \text{ MPa} \quad \mu = 1.78 \text{ D}$$

Supporting quantities:

Structural groups:

| Group            | $n_i$ | $C_i$ | Contribution |
|------------------|-------|-------|--------------|
| —CH <sub>3</sub> | 2     | 9.04  | 18.08        |
| >CH <sub>2</sub> | 1     | 6.47  | 6.47         |
| —COO—            | 1     | 13.41 | 13.41        |
| Total            |       |       | 37.96        |

$$T_r = (401.25 \text{ K})/(523.3 \text{ K}) = 0.767$$

From Eqs. (2-62) and (2-86):

$$\mu_r^* = 52.46 \frac{(1.78)^2(38.8)}{(523.3)^2} = 0.024$$

From Eq. (2-87):

$$A = 10^{-7} \frac{(88.1051)^{1/2}(523.3)}{37.96} = 1.294 \times 10^{-5}$$

Calculation using Eq. (2-84):

$$\frac{\eta^o}{\text{Pa}\cdot\text{s}} = \frac{(1.294 \times 10^{-5})(0.767)^2}{[1 + (0.36)(0.767)(0.767 - 1)]^{1/6}} \frac{1 + (270)(0.024)^4}{0.767 + (270)(0.024)^4} = 1.003 \times 10^{-5}$$

The estimated value is 1.5 percent lower than the DIPPR® 801 recommended value of  $1.018 \times 10^{-5}$  Pa·s.

The dependence of viscosity upon pressure is principally a density effect. Estimation of vapor viscosity at elevated pressures is commonly done by correlating density deviations from the low-pressure values, which are in turn estimated by using the procedures mentioned above. Several methods are available, but the method developed by Jossi et al. and extended to polar fluids by Stiel and Thodos is relatively accurate and easy to apply.

**Recommended Method** Jossi-Stiel-Thodos Method.

References: Stiel, L. I., and G. Thodos, *AIChE J.*, **10** (1964): 26; Jossi, J. A., L. I. Stiel, and G. Thodos, *AIChE J.*, **8** (1962): 59.

Classification: Empirical correlation and corresponding states.

Expected uncertainty: 9 percent—often less for nonpolar gases, larger for polar gases.

Applicability: Nonassociating gases;  $\rho_r < 2.6$ .

Input data:  $M$ ,  $T_c$ ,  $P_c$ ,  $Z_c$ ,  $\mu_r^*$ ,  $\eta^o$  (low-pressure viscosity at same  $T$  may be estimated by using methods given above), and  $\rho$  (may be calculated from  $T$  and  $P$  by using density methods given above).

## 2-506 PHYSICAL AND CHEMICAL DATA

*Description:* Deviation of  $\eta$  from the low-pressure value  $\eta^o$  is given by one of the following correlations depending upon its polarity and reduced density range:

For nonpolar gases,  $0.1 < \rho_r < 3.0$ :

$$\left[ \left( \frac{\eta - \eta^o}{\text{mPa}\cdot\text{s}} \right) \xi + 1 \right]^{1/4} = 1.0230 + 0.23364\rho_r - 0.58533\rho_r^2 - 0.40758\rho_r^3 + 0.093324\rho_r^4 \quad (2-89)$$

For polar gases,  $\rho_r \leq 0.1$ :

$$\left( \frac{\eta - \eta^o}{\text{mPa}\cdot\text{s}} \right) \xi = 1.656\rho_r^{1.111} \quad (2-90)$$

For polar gases,  $0.1 < \rho_r \leq 0.9$ :

$$\left( \frac{\eta - \eta^o}{\text{mPa}\cdot\text{s}} \right) \xi = 0.0607(9.045\rho_r + 0.63)^{1.739} \quad (2-91)$$

For polar gases,  $0.9 < \rho_r \leq 2.2$ :

$$\log \left\{ 4 - \log \left[ \left( \frac{\eta - \eta^o}{\text{mPa}\cdot\text{s}} \right) \xi \right] \right\} = 0.6439 - 0.1005\rho_r \quad (2-92)$$

For polar gases,  $2.2 < \rho_r \leq 2.6$ :

$$\log \left\{ 4 - \log \left[ \left( \frac{\eta - \eta^o}{\text{mPa}\cdot\text{s}} \right) \xi \right] \right\} = 0.6439 - 0.1005\rho_r - 0.000475(\rho_r^3 - 10.65)^2 \quad (2-93)$$

where  $\rho_r = P_c/(Z_cRT_c)$  and

$$\xi = 2173.4 \left( \frac{T_c}{\text{K}} \right)^{1/6} \left( \frac{M}{\text{kg/kmol}} \right)^{-1/2} \left( \frac{P_c}{\text{MPa}} \right)^{-2/3} \quad (2-94)$$

**Example** Estimate the vapor viscosity of  $\text{CO}_2$  at 350 K and 20 MPa if  $\eta^o = 0.0174$  mPa·s and  $Z = 0.4983$  (estimated from Lee-Kesler method, see section on density).

*Required properties:* From the DIPPR® 801 database,

$$M = 44.01 \text{ kg/kmol} \quad T_c = 304.21 \text{ K} \quad P_c = 7.383 \text{ MPa} \\ Z_c = 0.274 \quad \mu = 0 \text{ D (nonpolar)}$$

*Auxiliary quantities:*

$$\xi = 2173.4(304.21)^{1/6}(44.01)^{-1/2}(7.383)^{-2/3} = 224.1$$

$$\rho_r = \frac{7.383 \text{ MPa}}{0.274[8.314 \text{ m}^3\text{Pa}/(\text{K}\cdot\text{mol})](304.21 \text{ K})} = 10.654 \frac{\text{kmol}}{\text{m}^3}$$

$$\rho_r = \frac{\rho}{\rho_c} = \frac{P}{ZRT\rho_c} = \frac{20 \text{ MPa}}{0.4983[8.314 \text{ m}^3\text{Pa}/(\text{K}\cdot\text{mol})](350 \text{ K})(10.654 \text{ m}^3\cdot\text{kmol})} \\ = 1.295$$

*Calculation using Eq. (2-89) for nonpolar fluids:*

$$\left[ 224.1 \left( \frac{\eta - \eta^o}{\text{mPa}\cdot\text{s}} \right) + 1 \right]^{1/4} = 1.0230 + 0.23364(1.295) + 0.58533(1.295)^2 \\ - 0.40758(1.295)^3 + 0.093324(1.295)^4 = 1.684 \\ \eta = \frac{1.684^4 - 1}{224.1} \text{ mPa}\cdot\text{s} + 0.0174 \text{ mPa}\cdot\text{s} = 0.0489 \text{ mPa}\cdot\text{s}$$

This differs from the experimental value of 0.0473 mPa·s by 3.4 percent.

**Liquids** Liquid viscosity can be correlated as a function of temperature for low pressures. Usually the correlation is based on the Andrade equation [Andrade, E. N. da C., *Nature*, **125** (1930): 309]

$$\ln \eta = A + \frac{B}{T} \quad (2-95)$$

or an extension of it. For example, the DIPPR® 801 database uses the equation

$$\ln \eta = A + \frac{B}{T} + C \ln T + DT^E \quad (2-96)$$

which is analogous to the Riedel [Riedel, L., *Chem. Ing. Tech.*, **26** (1954): 83] vapor pressure equation.

Currently the most accurate method for predicting pure liquid viscosity is the following GC method.

**Recommended Method** Hsu method.

*Reference:* Hsu, H.-C., Y.-W. Sheu, and C.-H. Tu, *Chem. Eng. J.*, **88** (2002): 27.

*Classification:* Group contributions.

*Expected uncertainty:* 20 percent.

*Applicability:* Organic liquids;  $T_r < 0.75$ .

*Input data:*  $P_c$  and molecular structure.

*Description:* The temperature dependence of the liquid viscosity is given by

$$\ln \left( \frac{\eta}{\text{mPa}\cdot\text{s}} \right) = \sum_{i=1}^N a_i + T \sum_{i=1}^N b_i + \frac{\sum_{i=1}^N c_i}{T^2} + \left( \sum_{i=1}^N d_i \right) \ln \left( \frac{P_c}{\text{bar}} \right) \quad (2-97)$$

where  $P_c$  is critical pressure and the coefficients  $a$ ,  $b$ ,  $c$ , and  $d$  are the sum of the group contributions obtained from Table 2-356.

**Example** Estimate the liquid viscosity of benzotrifluoride at 303.15 K.

*Structural information:*

| Group               | Number | $a$     | $100b$  | $0.0001c$ | $d$     |
|---------------------|--------|---------|---------|-----------|---------|
| >C<                 | 1      | 1.0031  | -0.3677 | -6.0316   | 1.1972  |
| (=CH—) <sub>A</sub> | 5      | -0.8570 | -0.0098 | 2.4376    | 0.1311  |
| (=C<) <sub>A</sub>  | 1      | 0.7896  | -0.0231 | -0.9222   | 0.1928  |
| (—F) <sub>3</sub>   | 1      | 1.5394  | 0.8465  | 17.8121   | -2.9915 |
| Total               |        | -0.9529 | 0.4067  | 23.0463   | -0.9460 |

*Supporting values:*

$$P_c = 32.1 \text{ MPa}$$

*Calculation using Eq. (2-97):*

$$\frac{\eta}{\text{mPa}\cdot\text{s}} = \exp \left[ -0.9529 + (0.004067)(303.15) + \frac{230463}{(303.15)^2} - 0.9460 \ln 32.1 \right] \\ = 0.610$$

The estimated value is 20 percent higher than the DIPPR® 801 recommended value of 0.509 mPa·s.

**Liquid Mixtures** Almost all methods for estimating liquid mixture viscosity interpolate between the pure-component values at the same temperature. The Grunberg-Nissan [Grunberg, L., and A. H. Nissan, *Nature*, **164** (1949): 799] equation

$$\ln \eta = \sum_i^C x_i \ln \eta_i + \frac{1}{2} \sum_{i=1}^C \sum_{j=1}^C x_i x_j G_{ij} \quad (2-98)$$

is commonly used for nonaqueous mixtures. The parameter  $G_{ij}$  generally must be regressed from an experimental mixture viscosity. However, in the case of hydrocarbon mixtures  $G_{ij}$  can be set to zero with expected errors in the mixture viscosity of about 15 percent.

TABLE 2-356 Group Contributions for the Hsu et al. Method\*

Table-specific nomenclature: R = in nonaromatic ring, A = in aromatic ring, RC = attached to nonaromatic ring, AC = attached to aromatic ring, X = halogen,  $(-X)_n = n$  X atoms attached to same C atom

\*Hsu, H.-C., Y.-W. Sheu, and C.-H. Tu, *Chem. Eng. J.*, **88** (2002): 27

Estimation of liquid mixture viscosity without any mixture data is difficult because the viscosity is strongly affected by large molecular size differences and strong cross interactions between the different types of molecules. Viscosity-composition plots for aqueous mixtures can have maxima or minima, and viscosities for these mixtures are particularly difficult to estimate. The UNIFAC-VISCO method described below can be used to predict liquid viscosity of organic mixtures without any mixture data. It is relatively successful even for large differences in molecular size, but it is currently limited in scope by the small number of group contributions available.

**Recommended Method** UNIFAC-VISCO method.

*Reference:* Chevalier, J. L., P. Petrino, and Y. Gaston-Bonhomme, *Chem. Eng. Sci.*, **43** (1988): 1303; Gaston-Bonhomme, Y., P. Petrino, and J. L. Chevalier, *Chem. Eng. Sci.*, **49** (1994): 1799.

*Classification:* Group contributions.

*Expected uncertainty:* 20 percent.

*Applicability:* Organic liquids.

*Input data:* Molecular structure; pure-component molar volumes and viscosities at the mixture temperature.

*Description:* The equations for this method are

$$\ln\left(\frac{\eta}{\text{mPa}\cdot\text{s}}\right) = \sum_{i=1}^{\text{comp}} x_i \ln\left(\frac{\eta_i}{\text{mPa}\cdot\text{s}} \cdot \frac{V_i}{V_m}\right) + \frac{g^E}{RT} - \frac{g^E}{RT} \quad (2-99)$$

where  $V_m$  is the mixture molar volume and  $V_i$  is the pure-component molar volume of component  $i$ . The combinatorial and residual excess Gibbs energies are calculated exactly as in the UNIFAC method (see Sec. 13) with the exception that the group interactions  $\Psi_{mn}$  are calculated by using

$$\Psi_{mn} = \exp\left(-\frac{\alpha_{mn}}{298.15}\right) \quad (2-100)$$

The interaction parameters  $\alpha_{mn}$  are obtained from Table 2-357.

**Example** Estimate the viscosity of a mixture of 51.13 mol % ethanol(1) and 48.87 mol % benzene(2) at 298.15 K.

*Required input:* Values from the DIPPR® 801 database for the pure components at 298.15 K are  $\eta_1 = 1.0774$  mPa·s,  $\eta_2 = 0.5997$  mPa·s,  $V_1 = 0.05862$  m<sup>3</sup>/kmol, and  $V_2 = 0.08948$  m<sup>3</sup>/kmol.

|------------------|----------|----------|-----------|----------|--------------|
| Group            | <i>N</i> | <i>X</i> | <i>XQ</i> | $\Theta$ | $\ln \gamma$ |
| CH <sub>3</sub>  | 0        | 0        | 0         | 0        | 0.257        |
| CH <sub>2</sub>  | 0        | 0        | 0         | 0        | -0.728       |
| CH <sub>ar</sub> | 6        | 1        | 0.4       | 1        | 0.000        |
| OH               | 0        | 0        | 0         | 0        | 2.270        |
| Sum              | 6        |          | 0.4       |          |              |

Here  $\Theta$  and  $\ln \gamma$  are defined by the same equations shown above for the mixture groups.

UNIFAC residual term:

$$\frac{g^E}{RT} = \sum_{i=1}^2 x_i \left[ \sum_{m=1}^4 N_{m,i} (\ln \gamma_m - \ln \gamma_{m,i}) \right] = 0.3425$$

where  $N_m$  and  $\ln \gamma_m$  refer to the mixture and  $N_{m,i}$  and  $\ln \gamma_{m,i}$  refer to the pure-component values.

Mixture volume:

$$V_m = \sum_{i=1}^2 x_i V_i = 0.5113 \left( \frac{0.05862 \text{ m}^3}{\text{kmol}} \right) + 0.4887 \left( \frac{0.08948 \text{ m}^3}{\text{kmol}} \right) = 0.07370 \frac{\text{m}^3}{\text{kmol}}$$

Using Eq. (2-99):

$$\ln \left( \frac{\eta}{\text{mPa}\cdot\text{s}} \right) = 0.5113 \ln \left[ 1.0774 \left( \frac{0.05862}{0.07370} \right) \right] + 0.4887$$

$$\ln \left[ 0.5997 \left( \frac{0.08948}{0.07370} \right) \right] + 0.124 - 0.3425 = -0.4523$$

$$\eta = \exp(-0.4523) \text{ mPa}\cdot\text{s} = 0.636 \text{ mPa}\cdot\text{s}$$

The estimated value is 6.6 percent below the reported experimental value of 0.681 mPa·s [Kouris, S., and C. Panayiotou, *J. Chem. Eng. Data*, **34** (1989): 200].

## THERMAL CONDUCTIVITY

Thermal conductivity  $k$  is a measure of the rate at which heat conducts through the material and is defined as the proportionality constant in Fourier's law of heat conduction that relates the gradient of temperature to the heat flux or flow per unit area. In SI units, it has the units of W/(m·K). The conduction mechanism in low-density media, gases,

## 2-510 PHYSICAL AND CHEMICAL DATA

is primarily via molecular collisions, and  $k$  increases with increasing temperature (increasing molecular velocity). In dense media such as liquids, the energy transfer by conduction occurs more efficiently through the attractive intermolecular potential wells between the molecules than through collisions. As a result, liquid thermal conductivity generally decreases with increasing temperature (except for water, aqueous solutions, and a few multihydroxy and multiamine compounds), corresponding to the decrease in density with increased temperature. Below or near the normal boiling point, the temperature dependence of liquid thermal conductivity is nearly linear for modest temperature ranges and can be represented by

$$k = A - BT \quad (2-101)$$

where  $B$  is generally in the range of  $1 \times 10^{-4}$  to  $3 \times 10^{-4}$  W/(m·K<sup>2</sup>).

**Gases** Methods for estimating low-pressure gas thermal conductivities are based on kinetic theory and generally correlate the dimensionless group  $kM/\eta C_v$  ( $M$  = molecular weight,  $\eta$  = viscosity,  $C_v$  = isochoric heat capacity) known as the Eucken factor. The method of Stiel and Thodos is recommended for pure nonpolar compounds, and the method of Chung is recommended for pure polar compounds.

**Recommended Method** Stiel-Thodos method.

*Reference:* Stiel, L. I., and G. Thodos, *AIChE J.*, **10** (1964): 26.

*Classification:* Empirical extension of theory.

*Expected uncertainty:* 15 percent.

*Applicability:* Pure nonpolar gases at low pressure.

*Input data:*  $M$ ,  $T_c$ ,  $\eta$ , and  $C_v$ .

*Description:* The following equations may be used depending upon the molecular shape:

$$\frac{kM}{\eta C_v} = 2.5 \quad \text{monatomic} \quad (2-102)$$

$$\frac{kM}{\eta C_v} = 1.30 + \left(\frac{R}{C_v}\right) \left(1.7614 - \frac{0.3523}{T_r}\right) \quad \text{linear molecules} \quad (2-103)$$

$$\frac{kM}{\eta C_v} = 1.15 + 2.033 \left(\frac{R}{C_v}\right) \quad \text{nonlinear molecules} \quad (2-104)$$

where  $\eta$  = viscosity at same conditions as desired for  $k$ . *Note:* Because this method is only applicable at low pressures,  $C_v$  may be calculated as  $C_p - R$ , where  $C_p$  is the ideal gas isobaric heat capacity.

**Example** Estimate the low-pressure thermal conductivity of toluene vapor at 500 K.

*Required properties from the DIPPR® 801 database:*

$$T_c = 591.75 \text{ K} \quad M = 92.138 \text{ g/mol} \quad \eta(500 \text{ K}) = 1.1408 \times 10^{-5} \text{ Pa}\cdot\text{s}$$

$$C_v = C_p - R = (170.78 - 8.314) \text{ J/(mol}\cdot\text{K)} = 162.47 \text{ J/(mol}\cdot\text{K)}$$

*Auxiliary quantities:*

$$T_r = 500/591.75 = 0.845 \quad R/C_v = (8.314)/(162.47) = 0.0512$$

*From Eq. (2-104):*

$$k = [1.15 + (2.033)(0.0512)] \left[ \frac{(1.1408 \times 10^{-5} \text{ Pa}\cdot\text{s}) \left( \frac{162.47 \text{ J}}{\text{mol}\cdot\text{K}} \right)}{92.138 \frac{\text{g}}{\text{mol}}} \right] = 25.2 \frac{\text{mW}}{\text{m}\cdot\text{K}}$$

The estimated value is 18 percent below the DIPPR® 801 recommended value of 30.76 mW/(m·K).

**Recommended Method** Chung-Lee-Starling method.

*Reference:* Chung, T.-H., L. L. Lee, and K. E. Starling, *Ind. Eng. Chem. Fundam.*, **23** (1984): 8.

*Classification:* Corresponding states.

*Expected uncertainty:* 15 percent.

*Applicability:* Pure organic gases at low pressure.

*Input data:*  $C_v$ ,  $\omega$ ,  $T_c$ ,  $M$ , and  $\eta$ .

*Description:* The following equations apply:

$$\frac{kM}{\eta C_v} = 3.75 \Psi \left( \frac{R}{C_v} \right) \quad (2-105)$$

$$\Psi = 1 + \alpha \left( \frac{0.215 + 0.28288\alpha - 1.061\beta + 0.26665\gamma}{0.6366 + \beta\gamma + 1.061\alpha\beta} \right) \quad (2-106)$$

$$\alpha = \frac{C_v}{R} - 1.5 \quad \beta = 0.7862 - 0.7109\omega + 1.3168\omega^2$$

$$\gamma = 2.0 + 10.5T_r^2 \quad (2-107)$$

**Example** Estimate the low-pressure thermal conductivity of naphthalene vapor at 500 K.

*Required properties from the DIPPR® 801 database:*

$$T_c = 748.4 \text{ K} \quad M = 128.17 \text{ g/mol} \quad \omega = 0.30203$$

$$\eta(500 \text{ K}) = 1.0173 \times 10^{-5} \text{ Pa}\cdot\text{s}$$

$$C_v = C_p - R = (219.82 - 8.314) \text{ J/(mol}\cdot\text{K)} = 211.51 \text{ J/(mol}\cdot\text{K)}$$

*Auxiliary quantities [Eqs. (2-106) and (2-107)]:*

$$T_r = 500/748.4 = 0.6681 \quad R/C_v = (8.314)/(211.51) = 0.0393$$

$$\gamma = 2.0 + (10.5)(0.6681)^2 = 6.6866 \quad \alpha = (0.0393)^{-1} - 1.5 = 23.9388$$

$$\beta = 0.7862 - (0.7109)(0.30203) + (1.3168)(0.30203)^2 = 0.6916$$

$$\Psi = 1 + 23.9388$$

$$\times \left[ \frac{0.215 + 0.28288(23.9388) - 1.061(0.6916) + 0.26665(6.6866)}{0.6366 + 0.6916(6.6866) + 1.061(23.9388)(0.6916)} \right]$$

$$= 9.4273$$

*From Eq. (2-105):*

$$k = (3.75)(9.4273) \left[ \frac{(1.1408 \times 10^{-5} \text{ Pa}\cdot\text{s}) \left( \frac{8.314 \text{ J}}{\text{mol}\cdot\text{K}} \right)}{128.17 \frac{\text{g}}{\text{mol}}} \right] = 23.33 \frac{\text{mW}}{\text{m}\cdot\text{K}}$$

The estimated value is 1.0 percent above the DIPPR® 801 recommended value of 23.09 mW/(m·K).

**Liquids** The Baroncini method provides accurate liquid thermal conductivity estimates if the compound clearly belongs to one of the specific families designated by the correlation. The Sastri-Rao method is recommended for other specific families as listed in the discussion of the method given below. As a general method for estimating thermal conductivity of pure liquids at ambient pressure for all other compounds, the Missenard method is recommended.

**Recommended Method** Baroncini method.

*Reference:* Baroncini, C., et al., *Int. J. Thermophys.*, **2** (1981): 21.

*Classification:* Empirical correlation.

*Expected uncertainty:* 10 percent.

*Applicability:* Particularly accurate for the following families: acetates, aliphatic ethers, halogenated compounds, dicarboxylic acids, ketones, aliphatic alcohols, aliphatic acids, propionates and butyrates, and unsaturated aliphatic esters.

*Input data:*  $M$ ,  $T_b$  (normal boiling point),  $T_c$ .

*Description:*

$$\frac{k}{\text{W/(m}\cdot\text{K)}} = A \left( \frac{T_b}{K} \right)^\alpha \left( \frac{M}{\text{g/mol}} \right)^\beta \left( \frac{T_c}{K} \right)^{-\gamma} \frac{(1 - T_r)^{0.38}}{T_r^{1/6}} \quad (2-108)$$

where  $A$ ,  $\alpha$ ,  $\beta$ , and  $\gamma$  are obtained from Table 2-358.

**TABLE 2-358 Correlation Parameters for Baroncini et al. Method<sup>a</sup> for Estimation of Thermal Conductivity**

| Family                 | A       | $\alpha$ | $\beta$ | $\gamma$ |
|------------------------|---------|----------|---------|----------|
| Saturated hydrocarbons | 0.00350 | 1.2      | 0.5     | 0.167    |

| Aromatics              | 0.0346  | 1.2      | 1       | 0.167    |
| Alcohols               | 0.00339 | 1.2      | 0.5     | 0.167    |
| Organic acids          | 0.00319 | 1.2      | 0.5     | 0.167    |
| Ketones                | 0.00383 | 1.2      | 0.5     | 0.167    |
| Esters                 | 0.0415  | 1.2      | 1       | 0.167    |
| Ethers                 | 0.0385  | 1.2      | 1       | 0.167    |
| Refrigerants           |         |          |         |          |
| R20, R21, R22, R23     | 0.562   | 0        | 0.5     | -0.167   |
| Others                 | 0.494   | 0        | 0.5     | -0.167   |

<sup>a</sup>Baroncini, C., et al., *Int. J. Thermophys.*, **2** (1981): 21.

**Example** Estimate the thermal conductivity of liquid *p*-cresol at 400 K. Required properties from DIPPR<sup>®</sup> 801 database:

$$M = 108.1378 \text{ g/mol} \quad T_c = 704.65 \text{ K} \quad T_b = 475.133 \text{ K}$$

Auxiliary properties:

$$T_r = T/T_c = (400 \text{ K})/(704.65 \text{ K}) = 0.5677$$

From Table 2-358 for alcohols:

$$A = 0.00339 \quad \alpha = 1.2 \quad \beta = \frac{1}{2} \quad \gamma = 0.167$$

From Eq. (2-108):

$$\frac{k}{W/(m \cdot K)} = (0.00339)(475.13)^{1.2}(108.1378)^{-1/2}(704.65)^{-0.167}$$

$$\frac{(1 - 0.5677)^{0.38}}{0.5677^{1/6}} = 0.142$$

The estimated value is 7.6 percent higher than the DIPPR<sup>®</sup> 801 recommended value of 0.132 W/(m·K).

**Recommended Method** Sastri-Rao method.

*Reference:* Sastri, S. R. S., and K. K. Rao, *Chem. Eng. J.*, **74** (1999): 161.

*Classification:* Group contributions and corresponding states.

*Expected uncertainty:* 10 percent.

*Applicability:* Particularly accurate for the following families: alkanes, alkenes, aromatic alcohols, cycloalkanes, epoxides, aliphatic acids, condensed rings.

*Input data:*  $T_c$ ,  $T_b$  (normal boiling point), and molecular structure.

*Description:* The thermal conductivity at the normal boiling point  $k_b$  is calculated from the sum of the group contributions given in Table 2-359. This value is then scaled to the desired reduced temperature by using a factor  $\alpha^\beta$  in which the power  $\beta$  is related to the fractional reduced temperature distance between the normal boiling point and the critical point as shown in the following equations:

$$k_b = \sum_{i=1}^N n_i \Delta k_i \quad \beta = 1 - \left( \frac{1 - T_r}{1 - T_{br}} \right)^\gamma \quad k = k_b \alpha^\beta \quad (2-109)$$

where  $\gamma = 1.23$  for alcohols and 0.2 for all other compounds and  $\alpha = 0.856$  for alcohols and 0.16 for all other compounds.

**TABLE 2-359 Sastri-Rao<sup>a</sup> Group Contributions for Liquid Thermal Conductivity at the Normal Boiling Point**

| Group                    | $\Delta k_i$ (W/m·K) | Group                   | $\Delta k_i$ (W/m·K) |
|--------------------------|----------------------|-------------------------|----------------------|
| <b>Hydrocarbons</b>      |                      | —COOH                   | 0.0650               |

| Nonhydrocarbon groups but no hydrocarbon groups  | 0.1165                      |

<sup>a</sup>All rings are treated as separate rings in polycyclic compounds.

<sup>b</sup>Used only for aliphatic primary alcohols and phenols having no branch chains.

<sup>c</sup>Used in methane, formic acid, formates, etc.

<sup>d</sup>Used for all rings in polycyclic compounds with at least one nonhydrocarbon ring.

<sup>e</sup>The number of carbon atoms is nC.

<sup>f</sup>Aliphatic nonhydrocarbon liquids such as methylformate, acetanhydride, and ethylformate, having more than one type of nonhydrocarbon group and (1) one or two methyl groups or (2) one ethyl group only, require two correction factors. One is due to the hydrocarbon groups, and one is due to the presence of more than one type of nonhydrocarbon group.

## 2-512 PHYSICAL AND CHEMICAL DATA

**Example** Estimate the thermal conductivity of liquid methyl formate at 323 K.  
Molecular structure:

Group contributions from Table 2-359:

| Group  | $n_i$ | $\Delta k_i$ | $n_i \Delta k_i$ |
|--|-------|--------------|------------------|
| —CH <sub>3</sub>                                     | 1     | 0.0545       | 0.0545           |
| —COO—  | 1     | 0.0070       | 0.0070           |
| —H   | 1     | 0.0675       | 0.0675           |
| Corrections for multigroup interactions              |       |              |                  |
| Single CH <sub>3</sub> group + nonhydrocarbon groups |       |              | 0.0600           |
| More than one nonhydrocarbon with hydrocarbon groups |       |              | 0.0095           |
| Total  |       |              | 0.1985           |

Required input properties from DIPPR<sup>®</sup> 801 recommended values:

$$T_c = 487.2 \text{ K} \quad T_b = 304.9 \text{ K}$$

$$T_r = T/T_c = 323/487.2 = 0.6630 \quad T_{br} = 304.9/487.2 = 0.6258$$

From Eq. (2-109):

$$\alpha = 0.16 \quad \gamma = 0.2 \quad (\text{nonalcohol values})$$

$$\beta = 1 - \left( \frac{1 - 0.633}{1 - 0.6257} \right)^{0.2} = 0.0207 \quad k_b = 0.1985 \text{ W/(m}\cdot\text{K)}$$

$$k = [0.1985 \text{ W/(m}\cdot\text{K)}] (0.16)^{0.0207} = 0.1911 \text{ W/(m}\cdot\text{K)}$$

The estimated value is 10.2 percent above the DIPPR<sup>®</sup> 801 recommended value of 0.1734 W/(m·K).

**Recommended Method** Missenard method.

Reference: Missenard, A., *Comptes Rendus*, **260** (1965): 5521.

Classification: Corresponding states.

Expected uncertainty: 20 percent.

Applicability: Organic compounds; nonassociating.

Input data:  $T_c$ ,  $m$  (number of atoms in molecule),  $\rho_{273}$  (liquid density at 273.15 K),  $T_b$ ,  $M$ ,  $C_{p,273}$  (liquid heat capacity at 273.15 K).

Description:

$$\frac{k_{273}}{\text{mW/(m}\cdot\text{K)}} = \frac{8.4}{m^{1/4}} \cdot \left( \frac{T_b}{\text{K}} \right)^{1/2} \cdot \left( \frac{\rho_{273}}{\text{g/m}^3} \right)^{1/2} \cdot \left( \frac{M}{\text{g/mol}} \right)^{-1/2} \times \left[ \frac{C_{p,273}}{\text{J/(mol}\cdot\text{K)}} \right] \quad (2-110)$$

$$k = \frac{k_{273} [3 + 20(1 - T_r)^{2/3}]}{3 + 20(1 - T_{r,273})^{2/3}} \quad (2-111)$$

where  $T_{r,273} = (273 \text{ K})/T_c$ .

**Example** Estimate the thermal conductivity of *m*-xylene at 350 K.

Required properties from DIPPR<sup>®</sup> 801 database:

$$T_c = 617 \text{ K} \quad m = 18 \quad \rho_{273} = 7.6812 \text{ kmol/m}^3$$

$$T_b = 412.27 \text{ K} \quad M = 106.165 \text{ kg/kmol} \quad C_{p,273} = 200.64 \text{ kJ/(kmol}\cdot\text{K)}$$

Auxiliary properties:

$$T_r = 350/617 = 0.5673 \quad T_{br} = 412.27/617 = 0.6682$$

$$T_{r,273} = 273/617 = 0.4425$$

From Eq. (2-110):

$$\left( \frac{k_{273}}{\text{mW/(m}\cdot\text{K)}} \right) = (8.4)(412.27)^{1/2} (0.007681)^{1/2} (106.165)^{-1/2} (200.64)(18)^{-0.25} = 141.3$$

From Eq. (2-111):

$$k = \frac{k_{273} [3 + 20(1 - T_r)^{2/3}]}{3 + 20(1 - T_{r,273})^{2/3}} = \frac{\left( 141.3 \frac{\text{mW}}{\text{m}\cdot\text{K}} \right) [3 + 20(1 - 0.5673)^{2/3}]}{3 + 20(1 - 0.4425)^{2/3}} = 123.3 \frac{\text{mW}}{\text{m}\cdot\text{K}}$$

The estimated value is 4.5 percent above the DIPPR<sup>®</sup> 801 recommended value of 118.0 mW/(m·K).

**Liquid Mixtures** The thermal conductivity of liquid mixtures generally shows a modest negative deviation from a linear mass-fraction-weighted average of the pure-component values. Although more complex methods with some improved accuracy are available, two simple methods are recommended here that require very little additional information. The first method applies only to binary mixtures while the second can be used for multiple components.

**Recommended Method** Filippov correlation.

References: Filippov, L. P., *Vest. Mosk. Univ., Ser. Fiz. Mat. Estestv. Nauk*, **10** (1955): 67; Filippov, L. P., and N. S. Novoselova, *Sudgen, Vest. Mosk. Univ., Ser. Fiz. Mat. Estestv. Nauk*, **10** (1955): 37.

Classification: Empirical correlation.

Expected uncertainty: 4 to 8 percent.

Applicability: Binary liquid mixtures.

Input data: Pure-component thermal conductivities  $k_i$  at mixture conditions;  $w_i$ .

Description: The mixture thermal conductivity is calculated from the pure-component values using

$$k = w_1 k_1 + w_2 k_2 - 0.72 w_1 w_2 |k_2 - k_1| \quad (2-112)$$

where  $w_i$  is the mass fraction of pure fluid  $i$ .

**Recommended Method** Li correlation.

References: Li, C. C., *AIChE J.*, **22** (1976): 927.

Classification: Empirical correlation.

Expected uncertainty: 4 to 8 percent.

Applicability: Liquid mixtures.

Input data: Pure-component thermal conductivities  $k_i$  at mixture conditions;  $\rho_{L,i}$

Description: The mixture thermal conductivity is correlated as a function of the mixture volume fractions  $\phi_i$ :

$$k = \sum_{i=1}^C \sum_{j=1}^C \phi_i \phi_j \frac{2k_i k_j}{k_i + k_j} \quad (2-113)$$

$$\text{where } \phi_i = \frac{x_i \rho_{L,i}^{-1}}{\sum_{j=1}^C x_j \rho_{L,j}^{-1}}$$

**Example** Estimate the thermal conductivity of a mixture containing 30.2 mol % diethyl ether(1) and 69.8 mol % methanol(2) at 273.15 K and 0.1 MPa, using the Filippov and Li correlations.

Auxiliary data: The pure-component thermal conductivities and molar densities at 273.15 K recommended in the DIPPR<sup>®</sup> 801 database are

$$k_1 = 0.1383 \text{ W/(m}\cdot\text{K)} \quad \rho_1 = 9.9335 \text{ kmol/m}^3 \quad M_1 = 74.1216 \text{ kg/kmol}$$

$$k_2 = 0.2069 \text{ W/(m}\cdot\text{K)} \quad \rho_2 = 25.371 \text{ kmol/m}^3 \quad M_2 = 32.0419 \text{ kg/kmol}$$

The mass fractions corresponding to the mole fractions given above are

$$w_1 = 0.5 \quad w_2 = 0.5$$

The volume fractions are

$$\phi_1 = \frac{(0.302)(9.9335)^{-1}}{(0.302)(9.9335)^{-1} + (0.698)(25.371)^{-1}} = 0.525 \quad \phi_2 = 0.475$$

Calculation using Eq. (2-112):

$$k = [(0.5)(0.1383) + (0.5)(0.2069) - (0.72)(0.5)(0.5)(0.2069 - 0.1383)] \frac{W}{m \cdot K}$$

$$= 0.160 \text{ W/(m}\cdot\text{K)}$$

Calculation using Eq. (2-113):

$$k = \left[ (0.525)^2(0.1383) + 2 \cdot \frac{(0.525)(0.475)(2)(0.1383)(0.2069)}{0.1383 + 0.2069} + (0.475)^2(0.2069) \right] \frac{W}{m \cdot K}$$

$$= 0.167 \text{ W/(m}\cdot\text{K)}$$

The Filippov value is 7.5 percent lower than the experimental value of 0.173 W/(m·K) [Jamieson, D. T., and B. K. Hastings, *Thermal Conductivity, Proceedings of the Eighth Conference*, C. Y. Ho and R. E. Taylor, eds., Plenum Press, New York, 1969]; the Li value is 3.5 percent lower than the experimental value.

**Solids** There is no reliable method for estimating solid thermal conductivity at this time.

## SURFACE TENSION

The surface layer at a vapor-liquid interface is in tension and will contract to minimize the surface area. Qualitatively, the surface tension is due to the larger attractive forces that molecules at the interface experience from molecules in the dense liquid phase than from those in the low-density gas phase. Quantitatively, *surface tension* is defined as the force in the surface plane per unit length. Jasper [Jasper, J. J., *J. Phys. Chem. Ref. Data*, **1** (1972): 841] has made a critical evaluation of experimental surface tension data for approximately 2200 pure chemicals and correlated surface tension  $\sigma$  (mN/m = dyn/cm) with temperature as

$$\sigma = A - BT$$

Jasper's evaluation also includes values of  $A$  and  $B$  for most of the tabulated chemicals. Surface tension decreases with increasing temperature and increasing pressure.

**Pure Liquids** An approach suggested by Macleod [Macleod, D. B., *Trans. Faraday Soc.*, **19** (1923): 38] and modified by Sugden [Sugden, S. J., *Chem. Soc.*, **125** (1924): 32] relates  $\sigma$  to the liquid and vapor molar densities and a temperature-independent parameter called the parachor  $P$

$$\frac{\sigma}{\text{mN/m}} = \left[ P \cdot \left( \frac{\rho_L - \rho_V}{10^3 \text{ kmol/m}^3} \right) \right]^4 \quad (2-114)$$

where  $\rho_L$  and  $\rho_V$  are the saturated molar liquid and vapor densities, respectively. At low temperatures, where  $\rho_L \gg \rho_V$ , the vapor density can be neglected, but at higher temperatures the density of both phases must be calculated. At the critical point the surface tension is zero as  $\rho_L = \rho_V$ . Quayle [Quayle, O. R., *Chem. Rev.*, **53** (1953): 439] proposed a group contribution method for estimating  $P$  that has been improved in recent years by Knotts et al. [Knotts, T. A., et al., *J. Chem. Eng. Data*, **46** (2001): 1007]. This method using  $P$  is recommended when groups are available; otherwise, the Brock-Bird [Brock, J. R., and R. B. Bird, *AIChE J.*, **1** (1955): 174] corresponding-states method as modified by Miller [Miller, D. G., *Ind. Eng. Chem. Fundam.*, **2** (1963): 78] may be used to estimate surface tension for compounds that are not strongly polar or associating.

**Recommended Method** Parachor method.

*References:* Macleod, D. B., *Trans. Faraday Soc.*, **19** (1923): 38; Sugden, S. J., *Chem. Soc.*, **125** (1924): 32; Knotts, T. A., et al., *J. Chem. Eng. Data*, **46** (2001): 1007.

*Classification:* Group contributions and QSPR.

*Expected uncertainty:* 4 percent.

*Applicability:* Organic compounds for which group values are available.

*Input Data:*  $\rho_L$ , molecular structure, and Table 2-360.

*Description:* Equation (2-114) is used with  $P$  calculated from

$$P = \sum_{i=1}^N n_i \Delta P_i \quad (2-115)$$

Group values for the parachor are given in Table 2-360.

**Example** Estimate the surface tension of ethylacetylene at 237.45 K.  
*Structure:*

| Group                         | $n_i$ | $\Delta P_i$ | $n_i \Delta P_i$ |
|-------------------------------|-------|--------------|------------------|
| $\equiv \text{CH}$            | 1     | 43.64        | 43.64            |
| $\equiv \text{C}-$            | 1     | 28.64        | 28.64            |
| $>\text{CH}_2$ ( $n = 1-11$ ) | 1     | 39.92        | 39.92            |
| $\text{CH}_3$                 | 1     | 55.25        | 55.25            |
| Total                         |       |              | 167.45           |

*Required properties:* The DIPPR® 801 database gives  $\rho_L = 13.2573 \text{ kmol/m}^3$  at 237.45 K.

*Calculation using Eq. (2-114):*

$$\sigma = \left[ (167.45) \left( \frac{13.2573}{1000} \right) \right]^4 \frac{\text{mN}}{\text{m}} = 0.02429 \frac{\text{N}}{\text{m}}$$

The estimated value is 0.9 percent above the DIPPR® 801 recommended value of 0.02407 N/m.

**Recommended Method** Brock-Bird method.

*Reference:* Brock, J. R., and R. B. Bird, *AIChE J.*, **1** (1955): 174; Miller, D. G., *Ind. Eng. Chem. Fundam.*, **2** (1963): 78.

*Classification:* Corresponding states.

*Expected uncertainty:* 5 percent.

*Applicability:* Nonpolar and moderately polar organic compounds.

*Input data:*  $T_c$ ,  $P_c$ , and  $T_b$ .

*Description:*

$$\frac{\sigma}{\text{mN/m}} = (5.553 \times 10^{-5}) \left( \frac{P_c}{\text{Pa}} \right)^{2/3} \left( \frac{T_c}{\text{K}} \right)^{1/3} F(1 - T_r)^{11/9} \quad (2-116)$$

where

$$F = \frac{T_{br} [\ln(P_c/\text{Pa}) - 11.5261]}{1 - T_{br}} - 1.3281 \quad (2-117)$$

**Example** Estimate the surface tension for ethyl mercaptan at 303.15 K.

*Required properties from DIPPR® 801:*

$$T_c = 499.15 \text{ K} \quad P_c = 5.49 \times 10^6 \text{ Pa} \quad T_b = 308.15 \text{ K}$$

*Supporting quantities:*

$$T_r = (303.15 \text{ K}) / (499.15 \text{ K}) = 0.6073$$

$$T_{br} = (308.15 \text{ K}) / (499.15 \text{ K}) = 0.6173$$

$$F = [0.6173 [\ln(5.49 \times 10^6) - 11.5261] / (1 - 0.6173)] - 1.3281 = 5.113$$

[from Eq. (2-117)]

*From Eq. (2-116):*

$$\sigma = (5.553 \times 10^{-5}) (5.49 \times 10^6)^{2/3} (499.15)^{1/3} (5.113) (1 - 0.6073)^{11/9} \text{ mN/m}$$

$$= 22.36 \text{ mN/m}$$

The estimated value is 1.4 percent lower than the DIPPR® 801 recommended value of 22.68 mN/m.

TABLE 2-360 Knotts\* Group Contributions for the Parachor in Estimating Surface Tension

| Group                         | $\Delta P_i$ | Group                                     | $\Delta P_i$ |
|-------------------------------|--------------|---|--------------|

\*Knotts, T. A., et al., *J. Chem. Eng. Data*, **46** (2001): 1007.

**Liquid Mixtures** Compositions at the liquid-vapor interface are not the same as in the bulk liquid, and so simple (bulk) composition-weighted averages of the pure-fluid values do not provide quantitative estimates of the surface tension at the vapor-liquid interface of a mixture. The behavior of aqueous mixtures is more difficult to correlate and estimate than that of nonpolar mixtures because small amounts of organic material can have a pronounced effect upon the surface concentrations and the resultant surface tension. These effects are usually modeled with thermodynamic methods that account for the activity coefficients. For example, a UNIFAC method [Suarez, J. T. C. Torres-Marchal, and P. Rasmussen, *Chem. Eng. Sci.*, **44** (1989): 782] is recommended and illustrated in PGL5. For nonaqueous systems the extension of the parachor method, used above for pure fluids, is a simple and reasonably effective method for estimating  $\sigma$  for mixtures.

**Recommended Method** Parachor correlation.

Reference: Huggill, J. A., and A. J. van Welsenes, *Fluid Phase Equil.*, **29** (1986): 383; Macleod, D. B., *Trans. Faraday Soc.*, **19** (1923): 38; Sugden, S. J., *Chem. Soc.*, **125** (1924).

Classification: Corresponding states.

Expected uncertainty: 3 to 10 percent.

Applicability: Nonaqueous mixtures.

Input data: Liquid and vapor  $\rho$  at mixture  $T$ ; parachors of pure components;  $x_i$ .

Description:

$$\frac{\sigma_m}{\text{mN/m}} = \left( P_{L,m} \frac{\rho_{L,m}}{10^3 \text{ kmol/m}^3} - P_{V,m} \frac{\rho_{V,m}}{10^3 \text{ kmol/m}^3} \right)^4 \quad (2-118)$$

where  $\sigma_m$  = surface tension of the mixture

$P_{L,m}$  = parachor of liquid mixture

$P_{V,m}$  = parachor of vapor mixture

$\rho_{L,m}$  = liquid mixture molar density

$\rho_{V,m}$  = vapor mixture molar density

The following definitions are used for the liquid and vapor mixture parachors:

$$P_{L,m} = \frac{1}{2} \sum_{i=1}^C \sum_{j=1}^C x_i x_j (P_i + P_j) \quad P_{V,m} = \frac{1}{2} \sum_{i=1}^C \sum_{j=1}^C y_i y_j (P_i + P_j) \quad (2-119)$$

where  $x_i$  is the mole fraction of component  $i$  in the liquid and  $y_i$  is the mole fraction of component  $i$  in the vapor.

Note that  $\rho_v$  is generally very small compared to  $\rho_L$  at temperatures substantially lower than  $T_c$  and can often be neglected.

**Example** Estimate the surface tension for a 16.06 mol % *n*-pentane(1) + 83.94 mol % dichloromethane(2) mixture at 298.15 K.

Required properties from DIPPR® 801:

|                   | P     | $\rho_l$ /(kmol·m <sup>-3</sup> ) at 298.15 K |
|-------------------|-------|---|
| <i>n</i> -Pentane | 231.1 | 8.6173  |
| Dichloromethane   | 146.6 | 15.5211                                       |

Mixture parachor from Eq. (2-119) and mixture density:

$$P_{L,m} = (0.1606)^2(231.1) + (0.1606)(0.8394)(231.1 + 146.6) + (0.8394)^2(146.6) = 160.17$$

$$\rho_{L,m} = \left( \sum_{i=1}^C \frac{x_i}{\rho_i} \right)^{-1} = \left( \frac{0.1606}{8.6173} + \frac{0.8394}{15.5211} \right)^{-1} \frac{\text{kmol}}{\text{m}^3} = 13.752 \frac{\text{kmol}}{\text{m}^3}$$

Calculation using Eq. (2-118): Because the temperature is low, the density of the vapor can be neglected, and

$$\frac{\sigma_m}{\text{mN/m}} = [(160.17)(0.013752)]^4 = 23.54 \frac{\text{mN}}{\text{m}}$$

The estimated value is 2.9 percent below the experimental value of 24.24 mN/m reported by De Soria et al. [De Soria, M. L. G., et al., *J. Colloid Interface Sci.*, **103** (1985): 354].

## FLAMMABILITY PROPERTIES

Flash points, lower and upper flammability limits, and autoignition temperature are important properties for determining safe operating limits when processing organic compounds. As with any property, experimental values are preferable to predicted values, and prediction techniques for these properties are only modestly accurate.

The flash point is the lowest temperature at which a liquid gives off sufficient vapor to form an ignitable mixture with air near the surface of the liquid or within the vessel used. ASTM test methods include procedures using a closed-cup apparatus (ASTM D 56, ASTM D 93, and ASTM D 3828), which is preferred, and an open-cup apparatus (ASTM D 92 and ASTM D 1310). Closed-cup values are typically lower than open-cup values. When several values are available, the lowest reasonable temperature is usually accepted in order to ensure safe operations.

The lower and upper flammability limits are the boundary-line equilibrium mixtures of vapor or gas with air, which if ignited will just propagate a flame away from the ignition source. Each of these limits has a temperature at which the flammability limits are reached. The lower flammability limit temperature corresponds approximately to the flash point, but since the flash point is determined with downward flame propagation and nonuniform mixtures and the lower flammability temperature is determined with upward flame propagation and uniform vapor mixtures, the measured lower flammability temperature is often somewhat lower than the flash point.

The autoignition temperature is the minimum temperature for a substance to initiate self-combustion in air in the absence of an ignition source.

**Recommended Methods** Flash point: Thornton method.

Reference: As described by N. Y. Shebeko, A. V. Ivanov, and E. N. Alekhina, "Calculation of Flash Points and Ignition Temperatures of Organic Compounds," *Soviet Chem. Ind.* **16**(1984):1371.

Classification: Atomic contributions.

Expected uncertainty: 5 K.

Applicability: Organic compounds.

Input data: Number of carbon, hydrogen, sulfur, halogen, and oxygen atoms; vapor pressure correlation.

Description: A simple atom contribution method is given by

$$P^* - \frac{P_{\text{sys}}}{1 + 4.76(2\beta - 1)} = 0 \quad (2-120)$$

where  $P^*$  = vapor pressure at flash point temperature

$P_{\text{sys}}$  = total system pressure, typically  $1.01325 \times 10^5$  Pa

$\beta$  = stoichiometric coefficient, defined by

$$\beta = N_C + N_S + \frac{N_H - N_X}{4} - \frac{N_O}{2} \quad (2-121)$$

where  $N_C$  = number of carbon atoms in compound

$N_S$  = number of sulfur atoms in compound

$N_H$  = number of hydrogen atoms in compound

$N_X$  = number of halogen atoms in compound

$N_O$  = number of oxygen atoms in compound

Procedure:

Step 1. Determine the number of carbon, sulfur, hydrogen, halogen, and oxygen atoms in the compound.

Step 2. Calculate  $\beta$  from Eq. (2-121).

Step 3. Substitute a temperature-dependent expression for vapor pressure in Eq. (2-120) for  $P^*$ .

Step 4. Solve Eq. (2-120) for temperature. This temperature is the flash point estimate.

**Example** Estimate the flash point of phenol.

Structure:

Atomic contributions:

| Atom type | Number |
|-----------|--------|
| C         | 6      |
| H         | 6      |
| O         | 1      |

$$\beta = 6 + \frac{6}{4} - \frac{1}{2} = 7$$

The DIPPR® 801 correlation for the vapor pressure of phenol is

$$P^* = \exp(95.444 - \frac{10,113}{T} - 10.09 \ln T + 6.7603 \times 10^{-18} T^6)$$

When this expression is used in Eq. (2-120) and solved for temperature, one obtains  $T_{\text{FP}} = 348.7$  K, which is 1.2 percent below the DIPPR recommended value of 353 K.

**Recommended Method** Flammability limits: Pintar method.

Reference: Pintar, A. J., Technical Support Document DIPPR Project 912, Michigan Technological University, Houghton, 1996.

Classification: Group contributions.

Expected uncertainty: 25 percent.

| Na    | —                | —                | Si—N†              | 15.8960          | 1.6577           |
| Ni    | —                | —                | Si—Si              | —                | —                |

\*Pintar, A. J., Technical Support Document DIPPR Project 912, Michigan Technological University, Houghton, 1996.

†Does not include contribution of atoms attached to silicon.

**Applicability:** Organic and inorganic compounds.**Input data:** Group contributions from Tables 2-361 and 2-362.**Description:** A simple GC method with first-order contributions with lower flammability limit (LFL) and upper flammability limit (UFL) in volume % given by

$$\text{LFL} = \frac{100\%}{\sum n_i \text{LFL}_i} \quad (2-122)$$

$$\text{UFL} = \frac{100\%}{\sum n_i \text{UFL}_i} \quad (2-123)$$

where  $n_i$  = number of groups of type  $i$  in moleculeLFL<sub>*i*</sub> = contribution of group  $i$  to LFLUFL<sub>*i*</sub> = contribution of group  $i$  to UFL**Example** Estimate the lower and upper flammability limits of toluene.**Structure:****Group contributions:**

| Group                          | LFL     | UFL    |
|--------------------------------|---------|--------|
| —CH <sub>3</sub>               | 17.2750 | 3.8461 |
| —C <sub>6</sub> H <sub>5</sub> | 73.8338 | 9.6661 |

**Calculations using Eqs. (2-122) and (2-123):**

$$\text{LFL} = \frac{100\%}{17.2750 + 73.8338} = 1.10\%$$

$$\text{UFL} = \frac{100\%}{3.8461 + 9.6661} = 7.40\%$$

† Does not include contribution of atoms attached to silicon.

**TABLE 2-364 Group Contributions for Pintar\* Autoignition Temperature Method for Inorganic Compounds**

| Group | $b_i$    | Group              | $b_i$    | Group  | $b_i$   |
|-------|----------|--------------------|----------|--------|---------|
| B     | -457.14  | N                  | 0.71     | Si—C†  | -147.69 |
| Br    | —        | Na                 | —        | Si—O†  | -136.99 |
| C     | 489.19   | Ni                 | -1595.10 | Si—H†  | -310.52 |
| Cl    | 395.42   | >N—NH <sub>2</sub> | -215.02  | Si—Cl† | -200.88 |
| F     | —        | O                  | -13.39   | Si—N†  | —       |
| Fe    | -2050.90 | P                  | 108.45   | Si—Si  | —       |
| H     | 204.55   | S                  | -3.57    |        |         |

\*Pintar, A. J., *Estimation of Autoignition Temperature*, Technical Support Document DIPPR Project 912, Michigan Technological University, Houghton, 1996.

† Does not include contribution of atoms attached to silicon.

The values recommended in the DIPPR® 801 database are 1.2 and 7.1 percent, respectively.

Flammability temperatures are found by determining the temperature at which the vapor pressure equals the partial pressure corresponding to the LFL or UFL.

**Recommended Methods** Autoignition temperature: Pintar method.  
**Reference:** Pintar, A. J., *Estimation of Autoignition Temperature*, Technical Support Document DIPPR Project 912, Michigan Technological University, Houghton, 1996.

**Classification:** Group contributions.

**Expected uncertainty:** 25 percent.

**Applicability:** Organic and inorganic compounds.

**Input data:** Group contributions from Tables 2-363 and 2-364.

**Description:** A simple GC method with first-order contributions is given by

$$\text{AIT} = \sum n_i b_i \quad (2-124)$$

where  $n_i$  is the number of groups of type  $i$  in the molecule and  $b_i$  is the contribution of group  $i$  to the autoignition temperature. A more accurate but somewhat more complicated logarithmic GC method was also developed by Pintar in the same reference cited here.

**Example** Estimate the autoignition temperature of 2,3-dimethylpentane.  
**Structure and group information:**

| Group            | $n_i$ | $b_i$   |
|------------------|-------|---------|
| —CH <sub>3</sub> | 4     | 301.91  |
| >CH <sub>2</sub> | 1     | -10.86  |
| >CH—             | 2     | -275.17 |

Calculation using Eq. (2-124):

$$\text{AIT} = 4(301.91) - 10.86 + 2(-275.17) = 646.4 \text{ K}$$

The estimated value is 6.3 percent above the DIPPR® 801 recommended value of 608.15 K.

## MATHEMATICS

### GENERAL

The basic problems of the sciences and engineering fall broadly into three categories:

1. *Steady state problems.* In such problems the configuration of the system is to be determined. This solution does not change with time but continues indefinitely in the same pattern, hence the name "steady state." Typical chemical engineering examples include steady temperature distributions in heat conduction, equilibrium in chemical reactions, and steady diffusion problems.

2. *Eigenvalue problems.* These are extensions of equilibrium problems in which critical values of certain parameters are to be determined in addition to the corresponding steady-state configurations. The determination of eigenvalues may also arise in propagation problems and stability problems. Typical chemical engineering problems include those in heat transfer and resonance in which certain boundary conditions are prescribed.

3. *Propagation problems.* These problems are concerned with predicting the subsequent behavior of a system from a knowledge of the initial state. For this reason they are often called the transient (time-varying) or unsteady-state phenomena. Chemical engineering examples include the transient state of chemical reactions (kinetics), the propagation of pressure waves in a fluid, transient behavior of an adsorption column, and the rate of approach to equilibrium of a packed distillation column.

The mathematical treatment of engineering problems involves four basic steps:

1. *Formulation.* The expression of the problem in mathematical language. That translation is based on the appropriate physical laws governing the process.

2. *Solution.* Appropriate mathematical and numerical operations are accomplished so that logical deductions may be drawn from the mathematical model.

3. *Interpretation.* Development of relations between the mathematical results and their meaning in the physical world.

4. *Refinement.* The recycling of the procedure to obtain better predictions as indicated by experimental checks.

Steps 1 and 2 are of primary interest here. The actual details are left to the various subsections, and only general approaches will be discussed.

The formulation step may result in algebraic equations, difference equations, differential equations, integral equations, or combinations of these. In any event these mathematical models usually arise from statements of physical laws such as the laws of mass and energy conservation in the form

$$\text{Input of } x - \text{output of } x + \text{production of } x = \text{accumulation of } x$$

or

$$\text{Rate of input of } x - \text{rate of output of } x + \text{rate of production of } x = \text{rate of accumulation of } x$$

where  $x$  = mass, energy, etc. These statements may be abbreviated by the statement

$$\text{Input} - \text{output} + \text{production} = \text{accumulation}$$

Many general laws of the physical universe are expressible by differential equations. Specific phenomena are then singled out from the infinity of solutions of these equations by assigning the individual initial or boundary conditions which characterize the given problem. For steady state or boundary-value problems (Fig. 3-1) the solution must

FIG. 3-1 Boundary conditions.

satisfy the differential equation inside the region and the prescribed conditions on the boundary.

In mathematical language, the propagation problem is known as an initial-value problem (Fig. 3-2). Schematically, the problem is characterized by a differential equation plus an open region in which the equation holds. The solution of the differential equation must satisfy the initial conditions plus any "side" boundary conditions.

The description of phenomena in a "continuous" medium such as a gas or a fluid often leads to partial differential equations. In particular, phenomena of "wave" propagation are described by a class of partial differential equations called "hyperbolic," and these are essentially different in their properties from other classes such as those that describe equilibrium ("elliptic") or diffusion and heat transfer ("parabolic"). Prototypes are:

1. *Elliptic.* Laplace's equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$

Poisson's equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = g(x, y)$$

These do not contain the variable  $t$  (time) explicitly; accordingly, their solutions represent equilibrium configurations. Laplace's equation corresponds to a "natural" equilibrium, while Poisson's equation corresponds to an equilibrium under the influence of  $g(x, y)$ . Steady heat-transfer and mass-transfer problems are elliptic.

2. *Parabolic.* The heat equation

$$\frac{\partial u}{\partial t} = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2}$$

describes unsteady or propagation states of diffusion as well as heat transfer.

3. *Hyperbolic.* The wave equation

$$\frac{\partial^2 u}{\partial t^2} = \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2}$$

describes wave propagation of all types when the assumption is made that the wave amplitude is small and that interactions are linear.

FIG. 3-2 Propagation problem.

### 3-4 MATHEMATICS

The solution phase has been characterized in the past by a concentration on methods to obtain analytic solutions to the mathematical equations. These efforts have been most fruitful in the area of the linear equations such as those just given. However, many natural phenomena are nonlinear. While there are a few nonlinear problems that can be solved analytically, most cannot. In those cases, numerical methods are used. Due to the widespread availability of software for computers, the engineer has quite good tools available.

Numerical methods almost never fail to provide an answer to any particular situation, but they can never furnish a general solution of any problem.

The mathematical details outlined here include both analytic and numerical techniques useful in obtaining solutions to problems.

Our discussion to this point has been confined to those areas in which the governing laws are well known. However, in many areas, information on the governing laws is lacking and statistical methods are reused. Broadly speaking, statistical methods may be of use whenever conclusions are to be drawn or decisions made on the basis of experimental evidence. Since statistics could be defined as the technology of the scientific method, it is primarily concerned with the first two aspects of the method, namely, the performance of experiments and the drawing of conclusions from experiments. Traditionally the field is divided into two areas:

1. *Design of experiments.* When conclusions are to be drawn or decisions made on the basis of experimental evidence, statistical techniques are most useful when experimental data are subject to errors. The design of experiments may then often be carried out in such a fashion as to avoid some of the sources of experimental error and make the necessary allowances for that portion which is unavoidable. Second, the results can be presented in terms of probability statements which express the reliability of the results. Third, a statistical approach frequently forces a more thorough evaluation of the experimental aims and leads to a more definitive experiment than would otherwise have been performed.

2. *Statistical inference.* The broad problem of statistical inference is to provide measures of the uncertainty of conclusions drawn from experimental data. This area uses the theory of probability, enabling scientists to assess the reliability of their conclusions in terms of probability statements.

Both of these areas, the mathematical and the statistical, are intimately intertwined when applied to any given situation. The methods of one are often combined with the other. And both in order to be successfully used must result in the numerical answer to a problem—that is, they constitute the means to an end. Increasingly the numerical answer is being obtained from the mathematics with the aid of computers. The mathematical notation is given in Table 3-1.

#### MISCELLANEOUS MATHEMATICAL CONSTANTS

Numerical values of the constants that follow are approximate to the number of significant digits given.

|                           |   |
|---------------------------|---|
| $\pi = 3.1415926536$      | Pi  |
| $e = 2.7182818285$        | Napierian (natural) logarithm base          |
| $\gamma = 0.5772156649$   | Euler's constant                            |
| $\ln \pi = 1.1447298858$  | Napierian (natural) logarithm of pi, base e |
| $\log \pi = 0.4971498727$ | Briggsian (common logarithm of pi, base 10) |
| Radian = 57.2957795131°   |   |
| Degree = 0.0174532925 rad |   |
| Minute = 0.0002908882 rad |   |
| Second = 0.0000048481 rad |   |

$$\gamma = \lim_{n \rightarrow \infty} \left( \sum_{m=1}^n \frac{1}{m} - \ln n \right) = 0.577215$$

#### THE REAL-NUMBER SYSTEM

The natural numbers, or counting numbers, are the positive integers: 1, 2, 3, 4, 5, . . . . The negative integers are -1, -2, -3, . . . .

A number in the form  $a/b$ , where  $a$  and  $b$  are integers,  $b \neq 0$ , is a rational number. A real number that cannot be written as the quotient of two integers is called an irrational number, e.g.,  $\sqrt{2}$ ,  $\sqrt{3}$ ,  $\sqrt{5}$ ,  $\pi$ ,  $e$ ,  $\sqrt[3]{2}$ .

TABLE 3-1 Mathematical Signs, Symbols, and Abbreviations

|  |  |
|--|--|
| $\pm$ ( $\mp$ )                              | plus or minus (minus or plus)  |
| :  | divided by, ratio sign   |
| ::   | proportional sign  |
| <  | less than  |
| $\ll$  | not less than  |
| >  | greater than   |
| $\gg$  | not greater than   |
| $\cong$                                      | approximately equals, congruent  |
| $\sim$                                       | similar to   |
| $\simeq$                                     | equivalent to  |
| $\neq$                                       | not equal to   |
| $\doteq$                                     | approaches, is approximately equal to  |
| $\infty$                                     | varies as  |
| $\infty$                                     | infinity   |
| $\therefore$                                 | therefore  |
| $\sqrt{\quad}$                               | square root  |
| $\sqrt[3]{\quad}$                            | cube root  |
| $\sqrt[n]{\quad}$                            | $n$ th root  |
| $\angle$                                     | angle  |
| $\perp$                                      | perpendicular to   |
| $\parallel$                                  | parallel to  |
| $ x $  | numerical value of $x$   |
| $\log$ or $\log_{10}$                        | common logarithm or Briggsian logarithm  |
| $\log_e$ or $\ln$                            | natural logarithm or hyperbolic logarithm or Napierian logarithm   |
| $e$  | base (2.718) of natural system of logarithms   |
| $a^\circ$                                    | an angle $a$ degrees   |
| $a' a$                                       | prime, an angle $a$ minutes  |
| $a'' a$                                      | double prime, an angle $a$ seconds, $a$ second   |
| $\sin$                                       | sine   |
| $\cos$                                       | cosine   |
| $\tan$                                       | tangent  |
| $\text{ctn}$ or $\text{cot}$                 | cotangent  |
| $\sec$                                       | secant   |
| $\csc$                                       | cosecant   |
| $\text{vers}$                                | versed sine  |
| $\text{covers}$                              | covered sine   |
| $\text{exsec}$                               | exsecant   |
| $\sin^{-1}$                                  | anti sine or angle whose sine is   |
| $\sinh$                                      | hyperbolic sine  |
| $\cosh$                                      | hyperbolic cosine  |
| $\tanh$                                      | hyperbolic tangent   |
| $\sinh^{-1}$                                 | anti hyperbolic sine or angle whose hyperbolic sine is   |
| $f(x)$ or $\phi(x)$                          | function of $x$  |
| $\Delta x$                                   | increment of $x$   |
| $\Sigma$                                     | summation of   |
| $dx$   | differential of $x$  |
| $dy/dx$ or $y'$                              | derivative of $y$ with respect to $x$  |
| $d^2y/dx^2$ or $y''$                         | second derivative of $y$ with respect to $x$   |
| $d^n y/dx^n$                                 | $n$ th derivative of $y$ with respect to $x$   |
| $\partial y/\partial x$                      | partial derivative of $y$ with respect to $x$  |
| $\partial^n y/\partial x^n$                  | $n$ th partial derivative of $y$ with respect to $x$   |
| $\frac{\partial^n z}{\partial x \partial y}$ | $n$ th partial derivative with respect to $x$ and $y$  |
| $\int$                                       | integral of  |
| $\int_a^b$                                   | integral between the limits $a$ and $b$  |
| $\dot{y}$                                    | first derivative of $y$ with respect to time   |
| $\ddot{y}$                                   | second derivative of $y$ with respect to time  |
| $\Delta$ or $\nabla^2$                       | the "Laplacian"  |
|  | $\left( \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2} + \frac{\partial^2}{\partial z^2} \right)$ |
| $\delta$                                     | sign of a variation  |
| $\oint$                                      | sign for integration around a closed path  |

There is a one-to-one correspondence between the set of real numbers and the set of points on an infinite line (coordinate line).

**Order among Real Numbers; Inequalities**

- $a > b$  means that  $a - b$  is a positive real number.
- If  $a < b$  and  $b < c$ , then  $a < c$ .
- If  $a < b$ , then  $a \pm c < b \pm c$  for any real number  $c$ .
- If  $a < b$  and  $c > 0$ , then  $ac < bc$ .
- If  $a < b$  and  $c < 0$ , then  $ac > bc$ .
- If  $a < b$  and  $c < d$ , then  $a + c < b + d$ .
- If  $0 < a < b$  and  $0 < c < d$ , then  $ac < bd$ .
- If  $a < b$  and  $ab > 0$ , then  $1/a > 1/b$ .
- If  $a < b$  and  $ab < 0$ , then  $1/a < 1/b$ .

**Absolute Value** For any real number  $x$ ,  $|x| = \begin{cases} x & \text{if } x \geq 0 \\ -x & \text{if } x < 0 \end{cases}$

**Properties**

- If  $|x| = a$ , where  $a > 0$ , then  $x = a$  or  $x = -a$ .
- $|x| = |-x|$ ;  $-|x| \leq x \leq |x|$ ;  $|xy| = |x| |y|$ .
- If  $|x| < c$ , then  $-c < x < c$ , where  $c > 0$ .
- $||x| - |y|| \leq |x + y| \leq |x| + |y|$ .
- $\sqrt{x^2} = |x|$ .

**Proportions** If  $\frac{a}{b} = \frac{c}{d}$ , then  $\frac{a+b}{b} = \frac{c+d}{d}$ ,  $\frac{a-b}{b} = \frac{c-d}{d}$ ,  
 $\frac{a-b}{a+b} = \frac{c-d}{c+d}$ .

**Indeterminants**

| Form                    | Example                   |                                  |
|-------------------------|---------------------------|----------------------------------|
| $(\infty)(0)$           | $xe^{-x}$                 | $x \rightarrow \infty$           |
| $0^0$                   | $x^x$                     | $x \rightarrow 0^+$              |
| $\infty^0$              | $(\tan x)^{\cos x}$       | $x \rightarrow \frac{1}{2}\pi^-$ |
| $1^\infty$              | $(1+x)^{1/x}$             | $x \rightarrow 0^+$              |
| $\infty - \infty$       | $\sqrt{x+1} - \sqrt{x-1}$ | $x \rightarrow \infty$           |
| $\frac{0}{0}$           | $\frac{\sin x}{x}$        | $x \rightarrow 0$                |
| $\frac{\infty}{\infty}$ | $\frac{e^x}{x}$           | $x \rightarrow \infty$           |

**Integral Exponents (Powers and Roots)** If  $m$  and  $n$  are positive integers and  $a, b$  are numbers or functions, then the following properties hold:

$$\begin{aligned}
 a^{-n} &= 1/a^n & a \neq 0 \\
 (ab)^n &= a^n b^n \\
 (a^n)^m &= a^{nm}, & a^n a^m &= a^{n+m} \\
 \sqrt[n]{a} &= a^{1/n} & \text{if } a > 0 \\
 \sqrt[m]{\sqrt[n]{a}} &= \sqrt[mn]{a}, a > 0 \\
 a^{m/n} &= (a^m)^{1/n} = \sqrt[n]{a^m}, a > 0 \\
 a^0 &= 1 (a \neq 0) \\
 0^a &= 0 (a \neq 0)
 \end{aligned}$$

**Logarithms**  $\log ab = \log a + \log b, a > 0, b > 0$   
 $\log a^n = n \log a$   
 $\log (a/b) = \log a - \log b$   
 $\log \sqrt[n]{a} = (1/n) \log a$

The common logarithm (base 10) is denoted  $\log a$  or  $\log_{10} a$ . The natural logarithm (base  $e$ ) is denoted  $\ln a$  (or in some texts  $\log_e a$ ). If the text is ambiguous (perhaps using  $\log x$  for  $\ln x$ ), test the formula by evaluating it.

**Roots** If  $a$  is a real number,  $n$  is a positive integer, then  $x$  is called the  $n$ th root of  $a$  if  $x^n = a$ . The number of  $n$ th roots is  $n$ , but not all of them are necessarily real. The principal  $n$ th root means the following: (1) if  $a > 0$  the principal  $n$ th root is the unique positive root, (2) if

$a < 0$ , and  $n$  odd, it is the unique negative root, and (3) if  $a < 0$  and  $n$  even, it is any of the complex roots. In cases (1) and (2), the root can be found on a calculator by taking  $y = \ln a/n$  and then  $x = e^y$ . In case (3), see the section on complex variables.

**ALGEBRAIC INEQUALITIES**

**Arithmetic-Geometric Inequality** Let  $A_n$  and  $G_n$  denote respectively the arithmetic and the geometric means of a set of positive numbers  $a_1, a_2, \dots, a_n$ . The  $A_n \geq G_n$ , i.e.,

$$\frac{a_1 + a_2 + \dots + a_n}{n} \geq (a_1 a_2 \dots a_n)^{1/n}$$

The equality holds only if all of the numbers  $a_i$  are equal.

**Carleman's Inequality** The arithmetic and geometric means just defined satisfy the inequality

$$\sum_{r=1}^n (a_1 a_2 \dots a_r)^{1/r} \leq n e A_n$$

where  $e$  is the best possible constant in this inequality.

**Cauchy-Schwarz Inequality** Let  $a = (a_1, a_2, \dots, a_n)$ ,  $b = (b_1, b_2, \dots, b_n)$ , where the  $a_i$ 's and  $b_i$ 's are real or complex numbers. Then

$$\left| \sum_{k=1}^n a_k \bar{b}_k \right|^2 \leq \left( \sum_{k=1}^n |a_k|^2 \right) \left( \sum_{k=1}^n |b_k|^2 \right)$$

The equality holds if, and only if, the vectors  $a, b$  are linearly dependent (i.e., one vector is scalar times the other vector).

**Minkowski's Inequality** Let  $a_1, a_2, \dots, a_n$  and  $b_1, b_2, \dots, b_n$  be any two sets of complex numbers. Then for any real number  $p > 1$ ,

$$\left( \sum_{k=1}^n |a_k + b_k|^p \right)^{1/p} \leq \left( \sum_{k=1}^n |a_k|^p \right)^{1/p} + \left( \sum_{k=1}^n |b_k|^p \right)^{1/p}$$

**Hölder's Inequality** Let  $a_1, a_2, \dots, a_n$  and  $b_1, b_2, \dots, b_n$  be any two sets of complex numbers, and let  $p$  and  $q$  be positive numbers with  $1/p + 1/q = 1$ . Then

$$\left| \sum_{k=1}^n a_k \bar{b}_k \right| \leq \left( \sum_{k=1}^n |a_k|^p \right)^{1/p} \left( \sum_{k=1}^n |b_k|^q \right)^{1/q}$$

The equality holds if, and only if, the sequences  $|a_1|^p, |a_2|^p, \dots, |a_n|^p$  and  $|b_1|^q, |b_2|^q, \dots, |b_n|^q$  are proportional and the argument (angle) of the complex numbers  $a_k \bar{b}_k$  is independent of  $k$ . This last condition is of course automatically satisfied if  $a_1, \dots, a_n$  and  $b_1, \dots, b_n$  are positive numbers.

**Lagrange's Inequality** Let  $a_1, a_2, \dots, a_n$  and  $b_1, b_2, \dots, b_n$  be real numbers. Then

$$\left( \sum_{k=1}^n a_k b_k \right)^2 = \left( \sum_{k=1}^n a_k^2 \right) \left( \sum_{k=1}^n b_k^2 \right) - \sum_{1 \leq k < j \leq n} (a_k b_j - a_j b_k)^2$$

**Example** Two chemical engineers, John and Mary, purchase stock in the same company at times  $t_1, t_2, \dots, t_n$  when the price per share is respectively  $p_1, p_2, \dots, p_n$ . Their methods of investment are different, however: John purchases  $x$  shares each time, whereas Mary invests  $P$  dollars each time (fractional shares can be purchased). Who is doing better?

While one can argue intuitively that the average cost per share for Mary does not exceed that for John, we illustrate a mathematical proof using inequalities. The average cost per share for John is equal to

$$\frac{\text{Total money invested}}{\text{Number of shares purchased}} = \frac{x \sum_{i=1}^n p_i}{nx} = \frac{1}{n} \sum_{i=1}^n p_i$$

The average cost per share for Mary is

$$\frac{nP}{\sum_{i=1}^n \frac{P}{p_i}} = \frac{n}{\sum_{i=1}^n \frac{1}{p_i}}$$

### 3-6 MATHEMATICS

Thus the average cost per share for John is the arithmetic mean of  $p_1, p_2, \dots, p_n$ , whereas that for Mary is the harmonic mean of these  $n$  numbers. Since the harmonic mean is less than or equal to the arithmetic mean for any set of positive numbers and the two means are equal only if  $p_1 = p_2 = \dots = p_n$ , we conclude that the average cost per share for Mary is less than that for John if two of the prices  $p_i$  are distinct. One can also give a proof based on the Cauchy-Schwarz inequality. To this end, define the vectors

$$a = (p_1^{-1/2}, p_2^{-1/2}, \dots, p_n^{-1/2}) \quad b = (p_1^{1/2}, p_2^{1/2}, \dots, p_n^{1/2})$$

Then  $a \cdot b = 1 + \dots + 1 = n$ , and so by the Cauchy-Schwarz inequality

$$(a \cdot b)^2 = n^2 \leq \sum_{i=1}^n \frac{1}{p_i} \sum_{i=1}^n p_i$$

with the equality holding only if  $p_1 = p_2 = \dots = p_n$ . Therefore

$$\frac{n}{\sum_{i=1}^n \frac{1}{p_i}} \leq \frac{\sum_{i=1}^n p_i}{n}$$

## MENSURATION FORMULAS

**REFERENCES:** Liu, J., *Mathematical Handbook of Formulas and Tables*, McGraw-Hill, New York (1999); <http://mathworld.wolfram.com/SphericalSector.html>, etc.

Let  $A$  denote areas and  $V$  volumes in the following.

### PLANE GEOMETRIC FIGURES WITH STRAIGHT BOUNDARIES

**Triangles** (see also "Plane Trigonometry")  $A = \frac{1}{2}bh$  where  $b$  = base,  $h$  = altitude.

**Rectangle**  $A = ab$  where  $a$  and  $b$  are the lengths of the sides.

**Parallelogram** (opposite sides parallel)  $A = ah = ab \sin \alpha$  where  $a, b$  are the lengths of the sides,  $h$  the height, and  $\alpha$  the angle between the sides. See Fig. 3-3.

**Rhombus** (equilateral parallelogram)  $A = \frac{1}{2}ab$  where  $a, b$  are the lengths of the diagonals.

**Trapezoid** (four sides, two parallel)  $A = \frac{1}{2}(a + b)h$  where the lengths of the parallel sides are  $a$  and  $b$ , and  $h$  = height.

**Quadrilateral** (four-sided)  $A = \frac{1}{2}ab \sin \theta$  where  $a, b$  are the lengths of the diagonals and the acute angle between them is  $\theta$ .

**Regular Polygon of  $n$  Sides** See Fig. 3-4.

$$A = \frac{1}{4}nl^2 \cot \frac{180^\circ}{n} \quad \text{where } l = \text{length of each side}$$

$$R = \frac{l}{2} \csc \frac{180^\circ}{n} \quad \text{where } R \text{ is the radius of the circumscribed circle}$$

$$r = \frac{l}{2} \cot \frac{180^\circ}{n} \quad \text{where } r \text{ is the radius of the inscribed circle}$$

**Radius  $r$  of Circle Inscribed in Triangle with Sides  $a, b, c$**

$$r = \sqrt{\frac{(s-a)(s-b)(s-c)}{s}} \quad \text{where } s = \frac{1}{2}(a+b+c)$$

**Radius  $R$  of Circumscribed Circle**

$$R = \frac{abc}{4\sqrt{s(s-a)(s-b)(s-c)}}$$

FIG. 3-3 Parallelogram.

FIG. 3-4 Regular polygon.

FIG. 3-5 Circle.

### Area of Regular Polygon of $n$ Sides Inscribed in a Circle of Radius $r$

$$A = (nr^2/2) \sin (360^\circ/n)$$

### Perimeter of Inscribed Regular Polygon

$$P = 2nr \sin (180^\circ/n)$$

### Area of Regular Polygon Circumscribed about a Circle of Radius $r$

$$A = nr^2 \tan (180^\circ/n)$$

### Perimeter of Circumscribed Regular Polygon

$$P = 2nr \tan \frac{180^\circ}{n}$$

### PLANE GEOMETRIC FIGURES WITH CURVED BOUNDARIES

**Circle** (Fig. 3-5) Let

$C$  = circumference

$r$  = radius

$D$  = diameter

$A$  = area

$S$  = arc length subtended by  $\theta$

$l$  = chord length subtended by  $\theta$

$H$  = maximum rise of arc above chord,  $r - H = d$

$\theta$  = central angle (rad) subtended by arc  $S$

$C = 2\pi r = \pi D$  ( $\pi = 3.14159 \dots$ )

$S = r\theta = \frac{1}{2}D\theta$

$l = 2\sqrt{r^2 - d^2} = 2r \sin (\theta/2) = 2d \tan (\theta/2)$

$$d = \frac{1}{2} \sqrt{4r^2 - l^2} = \frac{1}{2} l \cot \frac{\theta}{2}$$

$$\theta = \frac{S}{r} = 2 \cos^{-1} \frac{d}{r} = 2 \sin^{-1} \frac{l}{D}$$

FIG. 3-6 Ellipse.

FIG. 3-7 Parabola.

$A$  (circle) =  $\pi r^2 = \frac{1}{4}\pi D^2$   
 $A$  (sector) =  $\frac{1}{2}rS = \frac{1}{2}r^2\theta$   
 $A$  (segment) =  $A$  (sector) -  $A$  (triangle) =  $\frac{1}{2}r^2(\theta - \sin \theta)$

**Ring** (area between two circles of radii  $r_1$  and  $r_2$ ) The circles need not be concentric, but one of the circles must enclose the other.

$A = \pi(r_1 + r_2)(r_1 - r_2)$   $r_1 > r_2$

**Ellipse** (Fig. 3-6) Let the semi-axes of the ellipse be  $a$  and  $b$

$A = \pi ab$   
 $C = 4aE(e)$

where  $e^2 = 1 - b^2/a^2$  and  $E(e)$  is the complete elliptic integral of the second kind,

$$E(e) = \frac{\pi}{2} \left[ 1 - \left(\frac{1}{2}\right)^2 e^2 + \dots \right]$$

[an approximation for the circumference  $C = 2\pi \sqrt{(a^2 + b^2)/2}$ ].

**Parabola** (Fig. 3-7)

Length of arc  $EFG = \sqrt{4x^2 + y^2} + \frac{y^2}{2x} \ln \frac{2x + \sqrt{4x^2 + y^2}}{y}$

Area of section  $EFG = \frac{4}{3}xy$

**Catenary** (the curve formed by a cord of uniform weight suspended freely between two points  $A, B$ ; Fig. 3-8)

$y = a \cosh (x/a)$

Length of arc between points  $A$  and  $B$  is equal to  $2a \sinh (L/a)$ . Sag of the cord is  $D = a \cosh (L/a) - a$ .

**SOLID GEOMETRIC FIGURES WITH PLANE BOUNDARIES**

**Cube** Volume =  $a^3$ ; total surface area =  $6a^2$ ; diagonal =  $a\sqrt{3}$ , where  $a$  = length of one side of the cube.

**Rectangular Parallelepiped** Volume =  $abc$ ; surface area =  $2(ab + ac + bc)$ ; diagonal =  $\sqrt{a^2 + b^2 + c^2}$ , where  $a, b, c$  are the lengths of the sides.

**Prism** Volume = (area of base)  $\times$  (altitude); lateral surface area = (perimeter of right section)  $\times$  (lateral edge).

**Pyramid** Volume =  $\frac{1}{3}$  (area of base)  $\times$  (altitude); lateral area of regular pyramid =  $\frac{1}{2}$  (perimeter of base)  $\times$  (slant height) =  $\frac{1}{2}$  (number of sides) (length of one side) (slant height).

FIG. 3-8 Catenary.

**Frustum of Pyramid** (formed from the pyramid by cutting off the top with a plane

$V = \frac{1}{3} (A_1 + A_2 + \sqrt{A_1 \cdot A_2})h$

where  $h$  = altitude and  $A_1, A_2$  are the areas of the base; lateral area of a regular figure =  $\frac{1}{2}$  (sum of the perimeters of base)  $\times$  (slant height).

**Volume and Surface Area of Regular Polyhedra with Edge  $l$**

| Type of surface          | Name              | Volume       | Surface area  |
|--------------------------|-------------------|--------------|---------------|
| 4 equilateral triangles  | Tetrahedron       | $0.1179 l^3$ | $1.7321 l^2$  |
| 6 squares                | Hexahedron (cube) | $1.0000 l^3$ | $6.0000 l^2$  |
| 8 equilateral triangles  | Octahedron        | $0.4714 l^3$ | $3.4641 l^2$  |
| 12 pentagons             | Dodecahedron      | $7.6631 l^3$ | $20.6458 l^2$ |
| 20 equilateral triangles | Icosahedron       | $2.1817 l^3$ | $8.6603 l^2$  |

**SOLIDS BOUNDED BY CURVED SURFACES**

**Cylinders** (Fig. 3-9)  $V$  = (area of base)  $\times$  (altitude); lateral surface area = (perimeter of right section)  $\times$  (lateral edge).

**Right Circular Cylinder**  $V = \pi$  (radius)<sup>2</sup>  $\times$  (altitude); lateral surface area =  $2\pi$  (radius)  $\times$  (altitude).

**Truncated Right Circular Cylinder**

$V = \pi r^2 h$ ; lateral area =  $2\pi r h$

$h = \frac{1}{2} (h_1 + h_2)$

**Hollow Cylinders** Volume =  $\pi h (R^2 - r^2)$ , where  $r$  and  $R$  are the internal and external radii and  $h$  is the height of the cylinder.

**Sphere** (Fig. 3-10)

$V$  (sphere) =  $\frac{4}{3}\pi R^3$ ,  $\frac{1}{6}\pi D^3$

$V$  (spherical sector) =  $\frac{2}{3}\pi R^2 h_i = 2$  (open spherical sector),  $i = 1$  (spherical cone)

$V$  (spherical segment of one base) =  $\frac{1}{6}\pi h_1 (3r_1^2 + h_1^2)$

$V$  (spherical segment of two bases) =  $\frac{1}{6}\pi h_2 (3r_1^2 + 3r_2^2 + h_2^2)$

$A$  (sphere) =  $4\pi R^2 = \pi D^2$

$A$  (zone) =  $2\pi R h = \pi D h$

$A$  (lune on the surface included between two great circles, the inclination of which is  $\theta$  radians) =  $2R^2\theta$ .

**Cone**  $V = \frac{1}{3}$  (area of base)  $\times$  (altitude).

**Right Circular Cone**  $V = (\pi/3) r^2 h$ , where  $h$  is the altitude and  $r$  is the radius of the base; curved surface area =  $\pi r \sqrt{r^2 + h^2}$ , curved surface of the frustum of a right cone =  $\pi(r_1 + r_2) \sqrt{h^2 + (r_1 - r_2)^2}$ , where  $r_1, r_2$  are the radii of the base and top, respectively, and  $h$  is the altitude; volume of the frustum of a right cone =  $\pi(h/3)(r_1^2 + r_1 r_2 + r_2^2) = h/3(A_1 + A_2 + \sqrt{A_1 A_2})$ , where  $A_1$  = area of base and  $A_2$  = area of top.

**Ellipsoid**  $V = (\frac{4}{3})\pi abc$ , where  $a, b, c$  are the lengths of the semi-axes.

**Torus** (obtained by rotating a circle of radius  $r$  about a line whose distance is  $R > r$  from the center of the circle)

$V = 2\pi^2 R r^2$  Surface area =  $4\pi^2 R r$

FIG. 3-9 Cylinder.

FIG. 3-10 Sphere.

### 3-8 MATHEMATICS

**Prolate Spheroid** (formed by rotating an ellipse about its major axis [2a])

$$\text{Surface area} = 2\pi b^2 + 2\pi(ab/e) \sin^{-1} e \quad V = \frac{4}{3}\pi ab^2$$

where  $a$ ,  $b$  are the major and minor axes and  $e = \text{eccentricity}$  ( $e < 1$ ).

**Oblate Spheroid** (formed by the rotation of an ellipse about its minor axis [2b]) Data as given previously.

$$\text{Surface area} = 2\pi a^2 + \pi \frac{b^2}{e} \ln \frac{1+e}{1-e} \quad V = \frac{4}{3}\pi a^2 b$$

For process vessels, the formulas reduce to the following:

#### Hemisphere

$$V = \frac{\pi}{12} D^3, \quad A = \frac{\pi}{2} D^2$$

For a hemisphere (concave up) partially filled to a depth  $h_1$ , use the formulas for spherical segment with one base, which simplify to

$$V = \pi h_1^2 (R - h_1/3) = \pi h_1^2 (D/2 - h_1/3)$$

$$A = 2\pi R h_1 = \pi D h_1$$

For a hemisphere (concave down) partially filled from the bottom, use the formulas for a spherical segment of two bases, one of which is a plane through the center, where  $h = \text{distance from the center plane to the surface of the partially filled hemisphere}$ .

$$V = \pi h (R^2 - h^2/3) = \pi h (D^2/4 - h^2/3)$$

$$A = 2\pi R h = \pi D h$$

**Cone** For a cone partially filled, use the same formulas as for right circular cones, but use  $r$  and  $h$  for the region filled.

**Ellipsoid** If the base of a vessel is one-half of an oblate spheroid (the cross section fitting to a cylinder is a circle with radius of  $D/2$  and the minor axis is smaller), then use the formulas for one-half of an oblate spheroid.

$$V = 0.1745D^3, \quad S = 1.236D^2, \quad \text{minor axis} = D/3$$

$$V = 0.1309D^3, \quad S = 1.084D^2, \quad \text{minor axis} = D/4$$

#### MISCELLANEOUS FORMULAS

See also "Differential and Integral Calculus."

**Volume of a Solid Revolution** (the solid generated by rotating a plane area about the  $x$  axis)

$$V = \pi \int_a^b [f(x)]^2 dx$$

where  $y = f(x)$  is the equation of the plane curve and  $a \leq x \leq b$ .

#### Area of a Surface of Revolution

$$S = 2\pi \int_a^b y ds$$

where  $ds = \sqrt{1 + (dy/dx)^2} dx$  and  $y = f(x)$  is the equation of the plane curve rotated about the  $x$  axis to generate the surface.

#### Area Bounded by $f(x)$ , the $x$ Axis, and the Lines $x = a$ , $x = b$

$$A = \int_a^b f(x) dx \quad [f(x) \geq 0]$$

#### Length of Arc of a Plane Curve

If  $y = f(x)$ ,

$$\text{Length of arc } s = \int_a^b \sqrt{1 + \left(\frac{dy}{dx}\right)^2} dx$$

If  $x = g(y)$ ,

$$\text{Length of arc } s = \int_c^d \sqrt{1 + \left(\frac{dx}{dy}\right)^2} dy$$

If  $x = f(t)$ ,  $y = g(t)$ ,

$$\text{Length of arc } s = \int_{t_0}^{t_1} \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt$$

In general,  $(ds)^2 = (dx)^2 + (dy)^2$ .

#### IRREGULAR AREAS AND VOLUMES

**Irregular Areas** Let  $y_0, y_1, \dots, y_n$  be the lengths of a series of equally spaced parallel chords and  $h$  be their distance apart (Fig. 3-11). The area of the figure is given approximately by any of the following:

$$A_T = (h/2)[(y_0 + y_n) + 2(y_1 + y_2 + \dots + y_{n-1})] \quad (\text{trapezoidal rule})$$

$$A_S = (h/3)[(y_0 + y_n) + 4(y_1 + y_3 + y_5 + \dots + y_{n-1}) + 2(y_2 + y_4 + \dots + y_{n-2})] \quad (n \text{ even, Simpson's rule})$$

The greater the value of  $n$ , the greater the accuracy of approximation.

**Irregular Volumes** To find the volume, replace the  $y$ 's by cross-sectional areas  $A_j$  and use the results in the preceding equations.

FIG. 3-11 Irregular area.

## ELEMENTARY ALGEBRA

**REFERENCES:** Stillwell, J. C., *Elements of Algebra*, CRC Press, New York (1994); Rich, B., and P. Schmidt, *Schaum's Outline of Elementary Algebra*, McGraw-Hill, New York (2004).

#### OPERATIONS ON ALGEBRAIC EXPRESSIONS

An algebraic expression will here be denoted as a combination of letters and numbers such as

$$3ax - 3xy + 7x^2 + 7x^{3/2} - 2.8xy$$

**Addition and Subtraction** Only like terms can be added or subtracted in two algebraic expressions.

**Example**  $(3x + 4xy - x^2) + (3x^2 + 2x - 8xy) = 5x - 4xy + 2x^2$ .

**Example**  $(2^x + 3xy - 4x^{1/2}) + (3^x + 6x - 8xy) = 2^x + 3^x + 6x - 5xy - 4x^{1/2}$ .

**Multiplication** Multiplication of algebraic expressions is term by term, and corresponding terms are combined.

**Example**  $(2x + 3y - 2xy)(3 + 3y) = 6x + 9y + 9y^2 - 6xy^2$ .

**Division** This operation is analogous to that in arithmetic.

**Example** Divide  $3e^{2x} + e^x + 1$  by  $e^x + 1$ .

$$\begin{array}{r}
 \text{Dividend} \\
 \text{Divisor } e^x + 1 \mid 3e^{2x} + e^x + 1 \quad \text{quotient} \\
 \underline{3e^{2x} + 3e^x} \\
 -2e^x + 1 \\
 \underline{-2e^x - 2} \\
 + 3 \text{ (remainder)}
 \end{array}$$

Therefore,  $3e^{2x} + e^x + 1 = (e^x + 1)(3e^x - 2) + 3$ .

**Operations with Zero** All numerical computations (except division) can be done with zero:  $a + 0 = 0 + a = a$ ;  $a - 0 = a$ ;  $0 - a = -a$ ;  $(a)(0) = 0$ ;  $a^0 = 1$  if  $a \neq 0$ ;  $0/a = 0$ ,  $a \neq 0$ .  $a/0$  and  $0/0$  have no meaning.

**Fractional Operations**

$$-\frac{x}{y} = -\left(\frac{-x}{-y}\right) = \frac{x}{-y} = \frac{-x}{y}; \quad \frac{x}{y} = \frac{-x}{-y}; \quad \frac{x}{y} = \frac{ax}{ay}, \text{ if } a \neq 0.$$

$$\frac{x}{y} \pm \frac{z}{y} = \frac{x \pm z}{y}; \quad \left(\frac{x}{y}\right)\left(\frac{z}{t}\right) = \frac{xz}{yt}; \quad \frac{x/y}{z/t} = \left(\frac{x}{y}\right)\left(\frac{t}{z}\right) = \frac{xt}{yz}$$

**Factoring** That process of analysis consisting of reducing a given expression into the product of two or more simpler expressions called *factors*. Some of the more common expressions are factored here:

- (1)  $(x^2 - y^2) = (x - y)(x + y)$
- (2)  $x^2 + 2xy + y^2 = (x + y)^2$
- (3)  $x^3 - y^3 = (x - y)(x^2 + xy + y^2)$
- (4)  $(x^3 + y^3) = (x + y)(x^2 - xy + y^2)$
- (5)  $(x^4 - y^4) = (x - y)(x + y)(x^2 + y^2)$
- (6)  $x^5 + y^5 = (x + y)(x^4 - x^3y + x^2y^2 - xy^3 + y^4)$
- (7)  $x^n - y^n = (x - y)(x^{n-1} + x^{n-2}y + x^{n-3}y^2 + \dots + y^{n-1})$

**Laws of Exponents**

$(a^n)^m = a^{nm}$ ;  $a^{n+m} = a^n \cdot a^m$ ;  $a^{n/m} = (a^n)^{1/m}$ ;  $a^{-n} = a^n/a^n$ ;  $a^{1/m} = m\sqrt{a}$ ;  $a^{1/2} = \sqrt{a}$ ;  $\sqrt{x^2} = |x|$  (absolute value of  $x$ ). For  $x > 0$ ,  $y > 0$ ,  $\sqrt{xy} = \sqrt{x}\sqrt{y}$ ; for  $x > 0$ ,  $\sqrt[n]{x^m} = x^{m/n}$ ;  $\sqrt[n]{1/x} = 1/\sqrt[n]{x}$

**THE BINOMIAL THEOREM**

If  $n$  is a positive integer,

$$\begin{aligned}
 (a + b)^n &= a^n + na^{n-1}b + \frac{n(n-1)}{2!} a^{n-2}b^2 \\
 &\quad + \frac{n(n-1)(n-2)}{3!} a^{n-3}b^3 + \dots + b^n = \sum_{j=0}^n \binom{n}{j} a^{n-j}b^j
 \end{aligned}$$

where  $\binom{n}{j} = \frac{n!}{j!(n-j)!}$  = number of combinations of  $n$  things taken  $j$  at a time.  $n! = 1 \cdot 2 \cdot 3 \cdot 4 \cdot \dots \cdot n$ ,  $0! = 1$ .

**Example** Find the sixth term of  $(x + 2y)^{12}$ . The sixth term is obtained by setting  $j = 5$ . It is

$$\binom{12}{5} x^{12-5}(2y)^5 = 792x^7(2y)^5$$

**Example**  $\sum_{j=0}^{14} \binom{14}{j} = (1 + 1)^{14} = 2^{14}$ .

If  $n$  is not a positive integer, the sum formula no longer applies and an infinite series results for  $(a + b)^n$ . The coefficients are obtained from the first formulas in this case.

**Example**  $(1 + x)^{1/2} = 1 + \frac{1}{2}x - \frac{1}{2} \cdot \frac{1}{4}x^2 + \frac{1}{2} \cdot \frac{1}{4} \cdot \frac{3}{6}x^3 \dots$  (convergent for  $x^2 < 1$ ).

Additional discussion is under "Infinite Series."

**PROGRESSIONS**

An arithmetic progression is a succession of terms such that each term, except the first, is derivable from the preceding by the addition of a quantity  $d$  called the common difference. All arithmetic progressions have the form  $a, a + d, a + 2d, a + 3d, \dots$ . With  $a$  = first term,  $l$  = last term,  $d$  = common difference,  $n$  = number of terms, and  $s$  = sum of the terms, the following relations hold:

$$\begin{aligned}
 l &= a + (n - 1)d = \frac{s}{n} + \frac{(n - 1)}{2} d \\
 s &= \frac{n}{2} [2a + (n - 1)d] = \frac{n}{2} (a + l) = \frac{n}{2} [2l - (n - 1)d] \\
 a &= l - (n - 1)d = \frac{s}{n} - \frac{(n - 1)d}{2} = \frac{2s}{n} - l \\
 d &= \frac{l - a}{n - 1} = \frac{2(s - an)}{n(n - 1)} = \frac{2(nl - s)}{n(n - 1)} \\
 n &= \frac{l - a}{d} + 1 = \frac{2s}{l + a}
 \end{aligned}$$

The **arithmetic mean or average** of two numbers  $a, b$  is  $(a + b)/2$ ; of  $n$  numbers  $a_1, \dots, a_n$  is  $(a_1 + a_2 + \dots + a_n)/n$ .

A **geometric progression** is a succession of terms such that each term, except the first, is derivable from the preceding by the multiplication of a quantity  $r$  called the common ratio. All such progressions have the form  $a, ar, ar^2, \dots, ar^{n-1}$ . With  $a$  = first term,  $l$  = last term,  $r$  = ratio,  $n$  = number of terms,  $s$  = sum of the terms, the following relations hold:

$$\begin{aligned}
 l &= ar^{n-1} = \frac{[a + (r - 1)s]}{r} = \frac{(r - 1)sr^{n-1}}{r^n - 1} \\
 s &= \frac{a(r^n - 1)}{r - 1} = \frac{a(1 - r^n)}{1 - r} = \frac{rl - a}{r - 1} = \frac{lr^n - l}{r^n - r^{n-1}} \\
 a &= \frac{l}{r^{n-1}} = \frac{(r - 1)s}{r^n - 1}, \quad r = \frac{s - a}{s - l}, \quad \log r = \frac{\log l - \log a}{n - 1} \\
 n &= \frac{\log l - \log a}{\log r} + 1 = \frac{\log[a + (r - 1)s] - \log a}{\log r}
 \end{aligned}$$

The geometric mean of two nonnegative numbers  $a, b$  is  $\sqrt{ab}$ ; of  $n$  numbers is  $(a_1 a_2 \dots a_n)^{1/n}$ . The geometric mean of a set of positive numbers is less than or equal to the arithmetic mean.

**Example** Find the sum of  $1 + \frac{1}{2} + \frac{1}{4} + \dots + \frac{1}{64}$ . Here  $a = 1$ ,  $r = \frac{1}{2}$ ,  $n = 7$ . Thus

$$\begin{aligned}
 s &= \frac{\frac{1}{2}(\frac{1}{64}) - 1}{\frac{1}{2} - 1} = 127/64 \\
 s &= a + ar + ar^2 + \dots + ar^{n-1} = \frac{a}{1 - r} - \frac{ar^n}{1 - r}
 \end{aligned}$$

If  $|r| < 1$ , then  $\lim_{n \rightarrow \infty} s = \frac{a}{1 - r}$

which is called the sum of the infinite geometric progression.

**Example** The present worth (PW) of a series of cash flows  $C_k$  at the end of year  $k$  is

$$PW = \sum_{k=1}^n \frac{C_k}{(1 + i)^k}$$

where  $i$  is an assumed interest rate. (Thus the present worth always requires specification of an interest rate.) If all the payments are the same,  $C_k = R$ , the present worth is

$$PW = R \sum_{k=1}^n \frac{1}{(1 + i)^k}$$

This can be rewritten as

$$PW = \frac{R}{1 + i} \sum_{k=1}^n \frac{1}{(1 + i)^{k-1}} = \frac{R}{1 + i} \sum_{j=0}^{n-1} \frac{1}{(1 + i)^j}$$

### 3-10 MATHEMATICS

This is a geometric series with  $r = 1/(1+i)$  and  $a = R/(1+i)$ . The formulas above give

$$PW (=s) = \frac{R}{i} \frac{(1+i)^n - 1}{(1+i)^n}$$

The same formula applies to the value of an annuity (PW) now, to provide for equal payments  $R$  at the end of each of  $n$  years, with interest rate  $i$ .

A progression of the form  $a, (a+d)r, (a+2d)r^2, (a+3d)r^3$ , etc., is a combined arithmetic and geometric progression. The sum of  $n$  such terms is

$$s = \frac{a - [a + (n-1)d]r^n}{1-r} + \frac{rd(1-r^{n-1})}{(1-r)^2}$$

If  $|r| < 1$ ,  $\lim_{n \rightarrow \infty} s = \frac{a}{1-r} + \frac{rd}{(1-r)^2}$ .

The non-zero numbers  $a, b, c$ , etc., form a harmonic progression if their reciprocals  $1/a, 1/b, 1/c$ , etc., form an arithmetic progression.

**Example** The progression  $1, \frac{1}{3}, \frac{1}{6}, \frac{1}{9}, \dots, \frac{1}{31}$  is harmonic since  $1, 3, 5, 7, \dots, 31$  form an arithmetic progression.

The **harmonic mean** of two numbers  $a, b$  is  $2ab/(a+b)$ .

### PERMUTATIONS, COMBINATIONS, AND PROBABILITY

Each separate arrangement of all or a part of a set of things is called a **permutation**. The number of permutations of  $n$  things taken  $r$  at a time, written

$$P(n, r) = \frac{n!}{(n-r)!} = n(n-1)(n-2) \cdots (n-r+1)$$

Each separate selection of objects that is possible irrespective of the order in which they are arranged is called a combination. The number of combinations of  $n$  things taken  $r$  at a time, written  $C(n, r) = n!/[r!(n-r)!]$ .

An important relation is  $r! C(n, r) = P(n, r)$ .

If an event can occur in  $p$  ways and fail to occur in  $q$  ways, all ways being equally likely, the **probability** of its occurrence is  $p/(p+q)$ , and that of its failure  $q/(p+q)$ .

**Example** Two dice may be thrown in 36 separate ways. What is the probability of throwing such that their sum is 7? Seven may arise in 6 ways: 1 and 6, 2 and 5, 3 and 4, 4 and 3, 5 and 2, 6 and 1. The probability of shooting 7 is  $1/6$ .

### THEORY OF EQUATIONS

**Linear Equations** A linear equation is one of the first degree (i.e., only the first powers of the variables are involved), and the process of obtaining definite values for the unknown is called solving the equation. Every linear equation in one variable is written  $Ax + B = 0$  or  $x = -B/A$ . Linear equations in  $n$  variables have the form

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + \cdots + a_{1n}x_n &= b_1 \\ a_{21}x_1 + a_{22}x_2 + \cdots + a_{2n}x_n &= b_2 \\ \vdots & \\ a_{m1}x_1 + a_{m2}x_2 + \cdots + a_{mn}x_n &= b_m \end{aligned}$$

The solution of the system may then be found by elimination or matrix methods if a solution exists (see "Matrix Algebra and Matrix Computations").

**Quadratic Equations** Every quadratic equation in one variable is expressible in the form  $ax^2 + bx + c = 0$ ,  $a \neq 0$ . This equation has two solutions, say,  $x_1, x_2$ , given by

$$x_{1,2} = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

If  $a, b, c$  are real, the discriminant  $b^2 - 4ac$  gives the character of the roots. If  $b^2 - 4ac > 0$ , the roots are real and unequal. If  $b^2 - 4ac < 0$ , the roots are complex conjugates. If  $b^2 - 4ac = 0$  the roots are **real and equal**. Two quadratic equations in two variables can in general be solved only by numerical methods (see "Numerical Analysis and Approximate Methods").

**Cubic Equations** A cubic equation, in one variable, has the form  $x^3 + bx^2 + cx + d = 0$ . Every cubic equation having complex coefficients has three complex roots. If the coefficients are real numbers, then at least one of the roots must be real. The cubic equation  $x^3 + bx^2 + cx + d = 0$  may be reduced by the substitution  $x = y - (b/3)$  to the form  $y^3 + py + q = 0$ , where  $p = \frac{1}{3}(3c - b^2)$ ,  $q = \frac{1}{27}(27d - 9bc + 2b^3)$ . This equation has the solutions  $y_1 = A + B$ ,  $y_2 = -\frac{1}{2}(A + B) + (i\sqrt{3}/2)(A - B)$ ,  $y_3 = -\frac{1}{2}(A + B) - (i\sqrt{3}/2)(A - B)$ , where  $i^2 = -1$ ,  $A = \sqrt[3]{-q/2 + \sqrt{R}}$ ,  $B = \sqrt[3]{-q/2 - \sqrt{R}}$ , and  $R = (p/3)^3 + (q/2)^2$ . If  $b, c, d$  are all real and if  $R > 0$ , there are one real root and two conjugate complex roots; if  $R = 0$ , there are three real roots, of which at least two are equal; if  $R < 0$ , there are three real unequal roots. If  $R < 0$ , these formulas are impractical. In this case, the roots are given by  $y_k = \sqrt[3]{2} \sqrt{-p/3} \cos[(\phi/3) + 120k]$ ,  $k = 0, 1, 2$  where

$$\phi = \cos^{-1} \sqrt{\frac{q^2/4}{-p^3/27}}$$

and the upper sign applies if  $q > 0$ , the lower if  $q < 0$ .

**Example**  $y^3 - 7y + 7 = 0$ ,  $p = -7$ ,  $q = 7$ ,  $R < 0$ . Hence

$$y_k = -\sqrt{\frac{28}{3}} \cos\left(\frac{\phi}{3} + 120k\right)$$

where  $\phi = \cos^{-1} \sqrt{\frac{27}{28}} \cdot \frac{\phi}{3} = 3.6311315 \text{ rad} = 3^\circ 37' 52''$

The roots are approximately  $-3.048917$ ,  $1.692021$ , and  $1.356896$ .

**Example** Many equations of state involve solving cubic equations for the compressibility factor  $Z$ . For example, the Redlich-Kwong-Soave equation of state requires solving

$$Z^3 - Z^2 + cZ + d = 0, \quad d < 0$$

where  $c$  and  $d$  depend on critical constants of the chemical species. In this case, only positive solutions,  $Z > 0$ , are desired.

**Quartic Equations** See Abramowitz and Stegun (1972, p. 17).

**General Polynomials of the  $n$ th Degree** Denote the general polynomial equation of degree  $n$  by

$$P(x) = a_0x^n + a_1x^{n-1} + \cdots + a_{n-1}x + a_n = 0$$

If  $n > 4$ , there is no formula which gives the roots of the general equation. For fourth and higher order (even third order), the roots can be found numerically (see "Numerical Analysis and Approximate Methods"). However, there are some general theorems that may prove useful.

**Remainder Theorems** When  $P(x)$  is a polynomial and  $P(x)$  is divided by  $x - a$  until a remainder independent of  $x$  is obtained, this remainder is equal to  $P(a)$ .

**Example**  $P(x) = 2x^4 - 3x^2 + 7x - 2$  when divided by  $x + 1$  (here  $a = -1$ ) results in  $P(x) = (x + 1)(2x^3 - 2x^2 - x + 8) - 10$  where  $-10$  is the remainder. It is easy to see that  $P(-1) = -10$ .

**Factor Theorem** If  $P(a)$  is zero, the polynomial  $P(x)$  has the factor  $x - a$ . In other words, if  $a$  is a root of  $P(x) = 0$ , then  $x - a$  is a factor of  $P(x)$ .

If a number  $a$  is found to be a root of  $P(x) = 0$ , the division of  $P(x)$  by  $(x - a)$  leaves a polynomial of degree one less than that of the original equation, i.e.,  $P(x) = Q(x)(x - a)$ . Roots of  $Q(x) = 0$  are clearly roots of  $P(x) = 0$ .

**Example**  $P(x) = x^3 - 6x^2 + 11x - 6 = 0$  has the root  $+3$ . Then  $P(x) = (x - 3)(x^2 - 3x + 2)$ . The roots of  $x^2 - 3x + 2 = 0$  are 1 and 2. The roots of  $P(x)$  are therefore 1, 2, 3.

**Fundamental Theorem of Algebra** Every polynomial of degree  $n$  has exactly  $n$  real or complex roots, counting multiplicities.

Every polynomial equation  $a_0x^n + a_1x^{n-1} + \cdots + a_n = 0$  with **rational coefficients** may be rewritten as a polynomial, of the same degree, with **integral coefficients** by multiplying each coefficient by the least common multiple of the denominators of the coefficients.

**Example** The coefficients of  $\frac{1}{2}x^4 + \frac{7}{3}x^3 - \frac{5}{6}x^2 + 2x - \frac{1}{6} = 0$  are rational numbers. The least common multiple of the denominators is  $2 \times 3 \times 6 = 6$ . Therefore, the equation is equivalent to  $9x^4 + 14x^3 - 5x^2 + 12x - 1 = 0$ .

**Determinants** Consider the system of two linear equations

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 &= b_1 \\ a_{21}x_1 + a_{22}x_2 &= b_2 \end{aligned}$$

If the first equation is multiplied by  $a_{22}$  and the second by  $-a_{12}$  and the results added, we obtain

$$(a_{11}a_{22} - a_{21}a_{12})x_1 = b_1a_{22} - b_2a_{12}$$

The expression  $a_{11}a_{22} - a_{21}a_{12}$  may be represented by the symbol

$$\begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix} = a_{11}a_{22} - a_{21}a_{12}$$

This symbol is called a determinant of second order. The value of the square array of  $n^2$  quantities  $a_{ij}$ , where  $i = 1, \dots, n$  is the row index,  $j = 1, \dots, n$  the column index, written in the form

$$|A| = \begin{vmatrix} a_{11} & a_{12} & \dots & a_{1n} \\ a_{21} & a_{22} & \dots & a_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ a_{n1} & a_{n2} & \dots & a_{nn} \end{vmatrix}$$

is called a determinant. The  $n^2$  quantities  $a_{ij}$  are called the elements of the determinant. In the determinant  $|A|$  let the  $i$ th row and  $j$ th column be deleted and a new determinant be formed having  $n - 1$  rows and columns. This new determinant is called the minor of  $a_{ij}$  denoted  $M_{ij}$ .

**Example**  $\begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix}$  The minor of  $a_{23}$  is  $M_{23} = \begin{vmatrix} a_{11} & a_{12} \\ a_{31} & a_{32} \end{vmatrix}$

The cofactor  $A_{ij}$  of the element  $a_{ij}$  is the signed minor of  $a_{ij}$  determined by the rule  $A_{ij} = (-1)^{i+j}M_{ij}$ . The value of  $|A|$  is obtained by forming any of the equivalent expressions  $\sum_{j=1}^n a_{ij}A_{ij}$ ,  $\sum_{i=1}^n a_{ij}A_{ij}$ , where the elements  $a_{ij}$  must be taken from a single row or a single column of  $A$ .

**Example**

$$\begin{vmatrix} a_{11} & a_{12} & a_{13} \\ a_{21} & a_{22} & a_{23} \\ a_{31} & a_{32} & a_{33} \end{vmatrix} = a_{31}A_{31} + a_{32}A_{32} + a_{33}A_{33}$$

$$= a_{31} \begin{vmatrix} a_{12} & a_{13} \\ a_{22} & a_{23} \end{vmatrix} - a_{32} \begin{vmatrix} a_{11} & a_{13} \\ a_{21} & a_{23} \end{vmatrix} + a_{33} \begin{vmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{vmatrix}$$

In general,  $A_{ij}$  will be determinants of order  $n - 1$ , but they may in turn be expanded by the rule. Also,

$$\sum_{j=1}^n a_{ji}A_{jk} = \sum_{j=1}^n a_{ij}A_{jk} = \begin{cases} |A| & i = k \\ 0 & i \neq k \end{cases}$$

**Fundamental Properties of Determinants**

1. The value of a determinant  $|A|$  is not changed if the rows and columns are interchanged.
2. If the elements of one row (or one column) of a determinant are all zero, the value of  $|A|$  is zero.
3. If the elements of one row (or column) of a determinant are multiplied by the same constant factor, the value of the determinant is multiplied by this factor.
4. If one determinant is obtained from another by interchanging any two rows (or columns), the value of either is the negative of the value of the other.
5. If two rows (or columns) of a determinant are identical, the value of the determinant is zero.
6. If two determinants are identical except for one row (or column), the sum of their values is given by a single determinant obtained by adding corresponding elements of dissimilar rows (or columns) and leaving unchanged the remaining elements.
7. The value of a determinant is not changed if one row (or column) is multiplied by a constant and added to another row (or column).

ANALYTIC GEOMETRY

**REFERENCES:** Fuller, G., *Analytic Geometry*, 7th ed., Addison Wesley Longman (1994); Larson, R., R. P. Hostetler, and B. H. Edwards, *Calculus with Analytic Geometry*, 7th ed., Houghton Mifflin (2001); Riddle, D. F., *Analytic Geometry*, 6th ed., Thompson Learning (1996); Spiegel, M. R., and J. Liu, *Mathematical Handbook of Formulas and Tables*, 2d ed., McGraw-Hill (1999); Thomas, G. B., Jr., and R. L. Finney, *Calculus and Analytic Geometry*, 9th ed., Addison-Wesley (1996).

Analytic geometry uses algebraic equations and methods to study geometric problems. It also permits one to visualize algebraic equations in terms of geometric curves, which frequently clarifies abstract concepts.

**PLANE ANALYTIC GEOMETRY**

**Coordinate Systems** The basic concept of analytic geometry is the establishment of a one-to-one correspondence between the points of the plane and number pairs  $(x, y)$ . This correspondence may be done in a number of ways. The rectangular or cartesian coordinate system consists of two straight lines intersecting at right angles (Fig. 3-12). A point is designated by  $(x, y)$ , where  $x$  (the abscissa) is the distance of the point from the  $y$  axis measured parallel to the  $x$  axis,

FIG. 3-12 Rectangular coordinates.

positive if to the right, negative to the left.  $y$  (ordinate) is the distance of the point from the  $x$  axis, measured parallel to the  $y$  axis, positive if above, negative if below the  $x$  axis. The quadrants are labeled 1, 2, 3, 4 in the drawing, the coordinates of points in the various quadrants having the depicted signs. Another common coordinate system is the polar coordinate system (Fig. 3-13). In this system the position of a point is designated by the pair  $(r, \theta)$ ,  $r = \sqrt{x^2 + y^2}$  being the distance to the origin  $(0,0)$  and  $\theta$  being the angle the line  $r$  makes with the positive  $x$  axis (polar axis). To change from polar to rectangular coordinates, use  $x = r \cos \theta$  and  $y = r \sin \theta$ . To change from rectangular to polar coordinates, use  $r = \sqrt{x^2 + y^2}$  and  $\theta = \tan^{-1}(y/x)$  if  $x \neq 0$ ;  $\theta = \pi/2$  if  $x = 0$ . The distance between two points  $(x_1, y_1)$ ,  $(x_2, y_2)$  is defined by  $d = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}$  in rectangular coordinates or by  $d = \sqrt{r_1^2 + r_2^2 - 2r_1r_2 \cos(\theta_1 - \theta_2)}$  in polar coordinates. Other coordinate systems are sometimes used. For example, on the surface of a sphere latitude and longitude prove useful.

**The Straight Line** (Fig. 3-14) The slope  $m$  of a straight line is the tangent of the inclination angle  $\theta$  made with the positive  $x$  axis. If

FIG. 3-13 Polar coordinates.

FIG. 3-14 Straight line.

### 3-12 MATHEMATICS

$(x_1, y_1)$  and  $(x_2, y_2)$  are any two points on the line, slope  $m = (y_2 - y_1)/(x_2 - x_1)$ . The slope of a line parallel to the  $x$  axis is zero; parallel to the  $y$  axis, it is undefined. Two lines are parallel if and only if they have the same slope. Two lines are perpendicular if and only if the product of their slopes is  $-1$  (the exception being that case when the lines are parallel to the coordinate axes). Every equation of the type  $Ax + By + C = 0$  represents a straight line, and every straight line has an equation of this form. A straight line is determined by a variety of conditions:

| Given conditions                           | Equation of line                                 |
|--|--|
| (1) Parallel to $x$ axis                   | $y = \text{constant}$                            |
| (2) Parallel $y$ axis                      | $x = \text{constant}$                            |
| (3) Point $(x_1, y_1)$ and slope $m$       | $y - y_1 = m(x - x_1)$                           |
| (4) Intercept on $y$ axis $(0, b)$ , $m$   | $y = mx + b$                                     |
| (5) Intercept on $x$ axis $(a, 0)$ , $m$   | $y = m(x - a)$                                   |
| (6) Two points $(x_1, y_1)$ , $(x_2, y_2)$ | $y - y_1 = \frac{y_2 - y_1}{x_2 - x_1}(x - x_1)$ |
| (7) Two intercepts $(a, 0)$ , $(0, b)$     | $x/a + y/b = 1$                                  |

The angle  $\beta$  a line with slope  $m_1$  makes with a line having slope  $m_2$  is given by  $\tan \beta = (m_2 - m_1)/(m_1 m_2 + 1)$ . A line is determined if the length and direction of the perpendicular to it (the normal) from the origin are given (see Fig. 3-15). Let  $p$  = length of the perpendicular and  $\alpha$  the angle that the perpendicular makes with the positive  $x$  axis. The equation of the line is  $x \cos \alpha + y \sin \alpha = p$ . The equation of a line perpendicular to a given line of slope  $m$  and passing through a point  $(x_1, y_1)$  is  $y - y_1 = -(1/m)(x - x_1)$ . The distance from a point  $(x_1, y_1)$  to a line with equation  $Ax + By + C = 0$  is

$$d = \frac{|Ax_1 + By_1 + C|}{\sqrt{A^2 + B^2}}$$

Occasionally some nonlinear algebraic equations can be reduced to linear equations under suitable substitutions or changes of variables. In other words, certain curves become the graphs of lines if the scales or coordinate axes are appropriately transformed.

**Example** Consider  $y = bx^n$ .  $B = \log b$ . Taking logarithms  $\log y = n \log x + \log b$ . Let  $Y = \log y$ ,  $X = \log x$ ,  $B = \log b$ . The equation then has the form  $Y = nX + B$ , which is a linear equation. Consider  $k = k_0 \exp(-E/RT)$ , taking logarithms  $\log_e k = \log_e k_0 - E/(RT)$ . Let  $Y = \log_e k$ ,  $B = \log_e k_0$ , and  $m = -E/R$ ,  $X = 1/T$ , and the result is  $Y = mX + B$ . Next consider  $y = a + bx^n$ . If the substitution  $t = x^n$  is made, then the graph of  $y$  is a straight line versus  $t$ .

**Asymptotes** The limiting position of the tangent to a curve as the point of contact tends to an infinite distance from the origin is called an **asymptote**. If the equation of a given curve can be expanded in a Laurent power series such that

$$f(x) = \sum_{k=0}^n a_k x^k + \sum_{k=1}^n \frac{b_k}{x^k}$$

and

$$\lim_{x \rightarrow \infty} f(x) = \sum_{k=0}^n a_k x^k$$

then the equation of the asymptote is  $y = \sum_{k=0}^n a_k x^k$ . If  $n = 1$ , then the asymptote is (in general oblique) a line. In this case, the equation of the asymptote may be written as

$$y = mx + b \quad m = \lim_{x \rightarrow \infty} f'(x)$$

$$b = \lim_{x \rightarrow \infty} [f(x) - xf'(x)]$$

FIG. 3-15 Determination of line.

**Geometric Properties of a Curve When the Equation Is Given** The analysis of the properties of an equation is facilitated by the investigation of the equation by using the following techniques:

1. *Points of maximum, minimum, and inflection.* These may be investigated by means of the calculus.
2. *Symmetry.* Let  $F(x, y) = 0$  be the equation of the curve.

| Condition on $F(x, y)$ | Symmetry                         |
|------------------------|----------------------------------|
| $F(x, y) = F(-x, y)$   | With respect to $y$ axis         |
| $F(x, y) = F(x, -y)$   | With respect to $x$ axis         |
| $F(x, y) = F(-x, -y)$  | With respect to origin           |
| $F(x, y) = F(y, x)$    | With respect to the line $y = x$ |

3. *Extent.* Only real values of  $x$  and  $y$  are considered in obtaining the points  $(x, y)$  whose coordinates satisfy the equation. The extent of them may be limited by the condition that negative numbers do not have real square roots.

4. *Intercepts.* Find those points where the curves of the function cross the coordinate axes.

5. *Asymptotes.* See preceding discussion.

6. *Direction at a point.* This may be found from the derivative of the function at a point. This concept is useful for distinguishing among a family of similar curves.

**Example**  $y^2 = (x^2 + 1)/(x^2 - 1)$  is symmetric with respect to the  $x$  and  $y$  axis, the origin, and the line  $y = x$ . It has the vertical asymptotes  $x = \pm 1$ . When  $x = 0$ ,  $y^2 = -1$ ; so there are no  $y$  intercepts. If  $y = 0$ ,  $(x^2 + 1)/(x^2 - 1) = 0$ ; so there are no  $x$  intercepts. If  $|x| < 1$ ,  $y^2$  is negative; so  $|x| > 1$ . From  $x^2 = (y^2 + 1)/(y^2 - 1)$ ,  $y = \pm 1$  are horizontal asymptotes and  $|y| > 1$ . As  $x \rightarrow 1^+$ ,  $y \rightarrow +\infty$ ; as  $x \rightarrow +\infty$ ,  $y \rightarrow +1$ . The graph is given in Fig. 3-16.

**Conic Sections** The curves included in this group are obtained from plane sections of the cone. They include the circle, ellipse, parabola, hyperbola, and degeneratively the point and straight line. A **conic** is the locus of a point whose distance from a fixed point called the **focus** is in a constant ratio to its distance from a fixed line, called the **directrix**. This ratio is the eccentricity  $e$ . If  $e = 0$ , the conic is a circle; if  $0 < e < 1$ , the conic is an ellipse; if  $e = 1$ , the conic is a parabola; if  $e > 1$ , the conic is a hyperbola. Every conic section is representable by an equation of second degree. Conversely, every equation of second degree in two variables represents a conic. The general equation of the second degree is  $Ax^2 + Bxy + Cy^2 + Dx + Ey + F = 0$ . Let  $\Delta$  be defined as the determinant

$$\Delta = \begin{vmatrix} 2A & B & D \\ B & 2C & E \\ D & E & 2F \end{vmatrix}$$

The table characterizes the curve represented by the equation.

|                 | $B^2 - 4AC < 0$   | $B^2 - 4AC = 0$   | $B^2 - 4AC > 0$               |
|-----------------|---|---|-------------------------------|
| $\Delta \neq 0$ | $A\Delta < 0$<br>$A \neq C$ , an ellipse<br>$A\Delta < 0$<br>$A = C$ , a circle<br>$A\Delta > 0$ , no locus | Parabola  | Hyperbola                     |
| $\Delta = 0$    | Point   | 2 parallel lines if $Q = D^2 + E^2 - 4(A + C)F > 0$<br>1 straight line if $Q = 0$ , no locus if $Q < 0$ | 2 intersecting straight lines |

FIG. 3-16 Graph of  $y^2 = (x^2 + 1)/(x^2 - 1)$ .

Some common equations in parametric form are given below.

|   |  |   |
|---|--|---|
| (1) $(x - h)^2 + (y - k)^2 = a^2$                       | $x = h + a \cos \theta$<br>$y = k + a \sin \theta$                 | Circle (Fig. 3-23) Parameter is angle $\theta$ .  |
| (2) $\frac{(x - h)^2}{a^2} + \frac{(y - k)^2}{b^2} = 1$ | $x = h + a \cos \phi$<br>$y = k + a \sin \phi$                     | Ellipse (Fig. 3-20) Parameter is angle $\phi$ .   |
| (3) $x^2 + y^2 = a^2$                                   | $x = \frac{-at}{\sqrt{t^2 + 1}}$<br>$y = \frac{a}{\sqrt{t^2 + 1}}$ | Circle Parameter is $t = \frac{dy}{dx}$ = slope of tangent at $(x, y)$ .                              |
| (4) $x^2 = y + k$                                       |  | Parabola (Fig. 3-22)  |
| (5) $\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$             |  | Hyperbola with the origin at the center (Fig. 3-21)   |
| (6) $y = a \cosh \frac{x}{a}$                           | $x = a \sinh^{-1} \frac{s}{a}$<br>$y^2 = a^2 + s^2$                | Catenary (such as hanging cable under gravity) Parameter $s$ = arc length from $(0, a)$ to $(x, y)$ . |
| (7) Cycloid   | $x = a(\phi - \sin \phi)$<br>$y = a(1 - \cos \phi)$                | Fig. 3.24   |

**Example**  $3x^2 + 4xy - 2y^2 + 3x - 2y + 7 = 0$ .

$$\Delta = \begin{vmatrix} 6 & 4 & 3 \\ 4 & -4 & -2 \\ 3 & -2 & 14 \end{vmatrix} = -596 \neq 0, B^2 - 4AC = 40 > 0$$

The curve is therefore a hyperbola.

The following tabulation gives the form of the more common equations.

| Polar equation                                       | Type of curve   |
|--|---|
| (1) $r = a$  | Circle, Fig. 3-17   |
| (2) $r = 2a \cos \theta$                             | Circle, Fig. 3-18   |
| (3) $r = 2a \sin \theta$                             | Circle, Fig. 3-19   |
| (4) $r^2 - 2br \cos(\theta - \beta) + b^2 - a^2 = 0$ | Circle at $(b, \beta)$ , radius $a$   |
| (5) $r = \frac{ke}{1 - e \cos \theta}$               | $e = 1$ parabola, Fig. 3-22<br>$0 < e < 1$ ellipse, Fig. 3-20<br>$e > 1$ hyperbola, Fig. 3-21 |

**Parametric Equations** It is frequently useful to write the equations of a curve in terms of an auxiliary variable called a parameter. For example, a circle of radius  $a$ , center at  $(0, 0)$ , can be written in the equivalent form  $x = a \cos \phi, y = a \sin \phi$  where  $\phi$  is the parameter.

Similarly,  $x = a \cos \phi, y = b \sin \phi$  are the parametric equations of the ellipse  $x^2/a^2 + y^2/b^2 = 1$  with parameter  $\phi$ .

**SOLID ANALYTIC GEOMETRY**

**Coordinate Systems** The commonly used coordinate systems are three in number. Others may be used in specific problems [see Morse, P. M., and H. Feshbach, *Methods of Theoretical Physics*, vols. I and II, McGraw-Hill, New York (1953)]. The **rectangular** (cartesian) system (Fig. 3-25) consists of mutually orthogonal axes  $x, y, z$ . A triple of numbers  $(x, y, z)$  is used to represent each point. The **cylindrical** coordinate system  $(r, \theta, z;$  Fig. 3-26) is frequently used to locate a point in space. These are essentially the polar coordinates  $(r, \theta)$  coupled with the  $z$  coordinate. As before,  $x = r \cos \theta, y = r \sin \theta, z = z$  and  $r^2 = x^2 + y^2, y/x = \tan \theta$ . If  $r$  is held constant and  $\theta$  and  $z$  are allowed to vary, the locus of  $(r, \theta, z)$  is a right circular cylinder of radius  $r$  along the  $z$  axis. The locus of  $r = C$  is a circle, and  $\theta = \text{constant}$  is a plane containing the  $z$  axis and making an angle  $\theta$  with the  $xz$  plane. Cylindrical coordinates are convenient to use when the problem has an axis of symmetry.

The **spherical** coordinate system is convenient if there is a point of symmetry in the system. This point is taken as the origin and the coordinates  $(\rho, \phi, \theta)$  illustrated in Fig. 3-27. The relations are  $x =$

**FIG. 3-17** Circle center  $(0,0) r = a$ .

**FIG. 3-18** Circle center  $(a,0) r = 2a \cos \theta$ .

**FIG. 3-19** Circle center  $(0,a) r = 2a \sin \theta$ .

**FIG. 3-20** Ellipse,  $0 < e < 1$ .

**FIG. 3-21** Hyperbola,  $e > 1$ .

**FIG. 3-22** Parabola,  $e = 1$ .

FIG. 3-23 Circle.

FIG. 3-24 Cycloid.

FIG. 3-25 Cartesian coordinates.

FIG. 3-26 Cylindrical coordinates.

FIG. 3-27 Spherical coordinates.

$\rho \sin \phi \cos \theta$ ,  $y = \rho \sin \phi \sin \theta$ ,  $z = \rho \cos \phi$ , and  $r = \rho \sin \phi$ .  $\theta = \text{constant}$  is a plane containing the  $z$  axis and making an angle  $\theta$  with the  $xz$  plane.  $\phi = \text{constant}$  is a cone with vertex at 0.  $\rho = \text{constant}$  is the surface of a sphere of radius  $\rho$ , center at the origin 0. Every point in the space may be given spherical coordinates restricted to the ranges  $0 \leq \phi \leq \pi$ ,  $\rho \geq 0$ ,  $0 \leq \theta < 2\pi$ .

**Lines and Planes** The distance between two points  $(x_1, y_1, z_1)$ ,  $(x_2, y_2, z_2)$  is  $d = \sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2 + (z_1 - z_2)^2}$ . There is nothing in the geometry of three dimensions quite analogous to the slope of a line in the plane case. Instead of specifying the direction of a line by a trigonometric function evaluated for one angle, a trigonometric function evaluated for three angles is used. The angles  $\alpha$ ,  $\beta$ ,  $\gamma$  that a line segment makes with the positive  $x$ ,  $y$ , and  $z$  axes, respectively, are called the **direction angles** of the line, and  $\cos \alpha$ ,  $\cos \beta$ ,  $\cos \gamma$  are called the **direction cosines**. Let  $(x_1, y_1, z_1)$ ,  $(x_2, y_2, z_2)$  be on the line. Then  $\cos \alpha = (x_2 - x_1)/d$ ,  $\cos \beta = (y_2 - y_1)/d$ ,  $\cos \gamma = (z_2 - z_1)/d$ , where  $d$  is the distance between the two points. Clearly  $\cos^2 \alpha + \cos^2 \beta + \cos^2 \gamma = 1$ . If two lines are specified by the direction cosines  $(\cos \alpha_1, \cos \beta_1, \cos \gamma_1)$ ,  $(\cos \alpha_2, \cos \beta_2, \cos \gamma_2)$ , then the angle  $\theta$  between the lines is  $\cos \theta = \cos \alpha_1 \cos \alpha_2 + \cos \beta_1 \cos \beta_2 + \cos \gamma_1 \cos \gamma_2$ . Thus the lines are perpendicular if and only if  $\theta = 90^\circ$  or  $\cos \alpha_1 \cos \alpha_2 + \cos \beta_1 \cos \beta_2 + \cos \gamma_1 \cos \gamma_2 = 0$ . The equation of a line with direction cosines  $(\cos \alpha, \cos \beta, \cos \gamma)$  passing through  $(x_1, y_1, z_1)$  is  $(x - x_1)/\cos \alpha = (y - y_1)/\cos \beta = (z - z_1)/\cos \gamma$ .

The equation of every plane is of the form  $Ax + By + Cz + D = 0$ . The numbers

$$\frac{A}{\sqrt{A^2 + B^2 + C^2}}, \frac{B}{\sqrt{A^2 + B^2 + C^2}}, \frac{C}{\sqrt{A^2 + B^2 + C^2}}$$

are direction cosines of the normal lines to the plane. The plane through the point  $(x_1, y_1, z_1)$  whose normals have these as direction cosines is  $A(x - x_1) + B(y - y_1) + C(z - z_1) = 0$ .

**Example** Find the equation of the plane through  $(1, 5, -2)$  perpendicular to the line  $(x + 9)/7 = (y - 3)/-1 = z/8$ . The numbers  $(7, -1, 8)$  are called **direction numbers**. They are a constant multiple of the direction cosines.  $\cos \alpha = 7/114$ ,  $\cos \beta = -1/114$ ,  $\cos \gamma = 8/114$ . The plane has the equation  $7(x - 1) - 1(y - 5) + 8(z + 2) = 0$  or  $7x - y + 8z + 14 = 0$ .

The distance from the point  $(x_1, y_1, z_1)$  to the plane  $Ax + By + Cz + D = 0$  is

$$d = \frac{|Ax_1 + By_1 + Cz_1 + D|}{\sqrt{A^2 + B^2 + C^2}}$$

**Space Curves** Space curves are usually specified as the set of points whose coordinates are given parametrically by a system of equations  $x = f(t)$ ,  $y = g(t)$ ,  $z = h(t)$  in the parameter  $t$ .

**Example** The equation of a straight line in space is  $(x - x_1)/a = (y - y_1)/b = (z - z_1)/c$ . Since all these quantities must be equal (say, to  $t$ ), we may write  $x = x_1 + at$ ,  $y = y_1 + bt$ ,  $z = z_1 + ct$ , which represent the parametric equations of the line.

**Example** The equations  $z = a \cos \beta t$ ,  $y = a \sin \beta t$ ,  $x = bt$ ,  $a, \beta, b$  positive constants, represent a circular helix.

FIG. 3-28 Parabolic cylinder.

**Surfaces** The locus of points  $(x, y, z)$  satisfying  $f(x, y, z) = 0$ , broadly speaking, may be interpreted as a surface. The simplest surface is the **plane**. The next simplest is a **cylinder**, which is a surface generated by a straight line moving parallel to a given line and passing through a given curve.

**Example** The parabolic cylinder  $y = x^2$  (Fig. 3-28) is generated by a straight line parallel to the  $z$  axis passing through  $y = x^2$  in the plane  $z = 0$ .

A surface whose equation is a quadratic in the variables  $x, y,$  and  $z$  is called a **quadric surface**. Some of the more common such surfaces are tabulated and pictured in Figs. 3-28 to 3-36.

FIG. 3-29 Ellipsoid.  $\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1$  (sphere if  $a = b = c$ )

$$\frac{x^2}{a^2} - \frac{y^2}{b^2} = 1$$

## PLANE TRIGONOMETRY

**REFERENCES:** Gelfand, I. M., and M. Saul, *Trigonometry*, Birkhäuser, Boston (2001); Heineman, E. Richard, and J. Dalton Tarwater, *Plane Trigonometry*, 7th ed., McGraw-Hill (1993).

### ANGLES

An angle is generated by the rotation of a line about a fixed center from some initial position to some terminal position. If the rotation is clockwise, the angle is negative; if it is counterclockwise, the angle is positive. Angle size is unlimited. If  $\alpha, \beta$  are two angles such that  $\alpha + \beta = 90^\circ$ , they are complementary; they are supplementary if  $\alpha + \beta = 180^\circ$ . Angles are most commonly measured in the sexagesimal system or by radian measure. In the first system there are 360 degrees in one complete revolution; one degree =  $\frac{1}{90}$  of a right angle. The degree is subdivided into 60 minutes; the minute is subdivided into 60 seconds. In the radian system one radian is the angle at the center of a circle subtended by an arc whose length is equal to the radius of the circle. Thus  $2\pi \text{ rad} = 360^\circ$ ;  $1 \text{ rad} = 57.29578^\circ$ ;  $1^\circ = 0.01745 \text{ rad}$ ;  $1 \text{ min} = 0.00029089 \text{ rad}$ . The advantage of radian measure is that it is *dimensionless*. The quadrants are conventionally labeled as Fig. 3-37 shows.

### FUNCTIONS OF CIRCULAR TRIGONOMETRY

The trigonometric functions of angles are the ratios between the various sides of the reference triangles shown in Fig. 3-38 for the various quadrants. Clearly  $r = \sqrt{x^2 + y^2} \geq 0$ . The fundamental functions (see Figs. 3-39, 3-40, 3-41) are

| 60             | $\pi/3$               | $\sqrt{3}/2$  | $1/2$         | $\sqrt{3}$    |
| 90             | $\pi/2$               | 1             | 0             | $+\infty$     |

If  $90^\circ \leq \theta \leq 180^\circ$ ,  $\sin \theta = \sin (180^\circ - \theta)$ ;  $\cos \theta = -\cos (180^\circ - \theta)$ ;  $\tan \theta = -\tan (180^\circ - \theta)$ . If  $180^\circ \leq \theta \leq 270^\circ$ ,  $\sin \theta = -\sin (270^\circ - \theta)$ ;  $\cos \theta = -\cos (270^\circ - \theta)$ ;  $\tan \theta = \tan (270^\circ - \theta)$ . If  $270^\circ \leq \theta \leq 360^\circ$ ,  $\sin \theta = -\sin (360^\circ - \theta)$ ;  $\cos \theta = \cos (360^\circ - \theta)$ ;  $\tan \theta = -\tan (360^\circ - \theta)$ . The reciprocal properties may be used to find the values of the other functions.

If it is desired to find the angle when a function of it is given, the procedure is as follows: There will in general be two angles between  $0^\circ$  and  $360^\circ$  corresponding to the given value of the function.

| Given ( $a > 0$ )  | Find an acute angle $\theta_0$ such that | Required angles are                               |
|--------------------|--|---|
| $\sin \theta = +a$ | $\sin \theta_0 = a$                      | $\theta_0$ and $(180^\circ - \theta_0)$           |
| $\cos \theta = +a$ | $\cos \theta_0 = a$                      | $\theta_0$ and $(360^\circ - \theta_0)$           |
| $\tan \theta = +a$ | $\tan \theta_0 = a$                      | $\theta_0$ and $(180^\circ + \theta_0)$           |
| $\sin \theta = -a$ | $\sin \theta_0 = a$                      | $180^\circ + \theta_0$ and $360^\circ - \theta_0$ |
| $\cos \theta = -a$ | $\cos \theta_0 = a$                      | $180^\circ - \theta_0$ and $180^\circ + \theta_0$ |
| $\tan \theta = -a$ | $\tan \theta_0 = a$                      | $180^\circ - \theta_0$ and $360^\circ - \theta_0$ |

**Relations between Functions of a Single Angle**  $\sec \theta = 1/\cos \theta$ ;  $\csc \theta = 1/\sin \theta$ ,  $\tan \theta = \sin \theta/\cos \theta = \sec \theta/\csc \theta = 1/\cot \theta$ ;  $\sin^2 \theta + \cos^2 \theta = 1$ ;  $1 + \tan^2 \theta = \sec^2 \theta$ ;  $1 + \cot^2 \theta = \csc^2 \theta$ . For  $0 \leq \theta \leq 90^\circ$  the following results hold:

$$\sin \theta = 2 \sin \left( \frac{\theta}{2} \right) \cos \left( \frac{\theta}{2} \right)$$

FIG. 3-37 Quadrants.

FIG. 3-38 Triangles.

FIG. 3-39 Graph of  $y = \sin x$ .

FIG. 3-40 Graph of  $y = \cos x$ .

FIG. 3-41 Graph of  $y = \tan x$ .

$$\text{and } \cos \theta = \cos^2\left(\frac{\theta}{2}\right) - \sin^2\left(\frac{\theta}{2}\right)$$

The cofunction property is very important.  $\cos \theta = \sin(90^\circ - \theta)$ ,  $\sin \theta = \cos(90^\circ - \theta)$ ,  $\tan \theta = \cot(90^\circ - \theta)$ ,  $\cot \theta = \tan(90^\circ - \theta)$ , etc.

**Functions of Negative Angles**  $\sin(-\theta) = -\sin \theta$ ,  $\cos(-\theta) = \cos \theta$ ,  $\tan(-\theta) = -\tan \theta$ ,  $\sec(-\theta) = \sec \theta$ ,  $\csc(-\theta) = -\csc \theta$ ,  $\cot(-\theta) = -\cot \theta$ .

**Identities**

**Sum and Difference Formulas** Let  $x, y$  be two angles.  $\sin(x \pm y) = \sin x \cos y \pm \cos x \sin y$ ;  $\cos(x \pm y) = \cos x \cos y \mp \sin x \sin y$ ;  $\tan(x \pm y) = \frac{\tan x \pm \tan y}{1 \mp \tan x \tan y}$ ;  $\sin x \pm \sin y = 2 \sin \frac{1}{2}(x \pm y) \cos \frac{1}{2}(x \mp y)$ ;  $\cos x + \cos y = 2 \cos \frac{1}{2}(x + y) \cos \frac{1}{2}(x - y)$ ;  $\cos x - \cos y = -2 \sin \frac{1}{2}(x + y) \sin \frac{1}{2}(x - y)$ ;  $\tan x \pm \tan y = \frac{\sin(x \pm y)}{\cos x \cos y}$ ;  $\sin^2 x - \sin^2 y = \cos^2 y - \cos^2 x = \sin(x + y) \sin(x - y)$ ;  $\cos^2 x - \sin^2 y = \cos^2 y - \sin^2 x = \cos(x + y) \cos(x - y)$ ;  $\sin(45^\circ + x) = \cos(45^\circ - x)$ ;  $\sin(45^\circ - x) = \cos(45^\circ + x)$ ;  $\tan(45^\circ \pm x) = \cot(45^\circ \mp x)$ .

**Multiple and Half Angle Identities** Let  $x = \text{angle}$ ,  $\sin 2x = 2 \sin x \cos x$ ;  $\sin x = 2 \sin \frac{1}{2}x \cos \frac{1}{2}x$ ;  $\cos 2x = \cos^2 x - \sin^2 x = 1 - 2 \sin^2 x = 2 \cos^2 x - 1$ .  $\tan 2x = \frac{2 \tan x}{1 - \tan^2 x}$ ;  $\sin 3x = 3 \sin x - 4 \sin^3 x$ ;  $\cos 3x = 4 \cos^3 x - 3 \cos x$ .  $\tan 3x = \frac{3 \tan x - \tan^3 x}{1 - 3 \tan^2 x}$ ;  $\sin 4x = 4 \sin x \cos x - 8 \sin^3 x \cos x$ ;  $\cos 4x = 8 \cos^4 x - 8 \cos^2 x + 1$ .

$$\sin\left(\frac{x}{2}\right) = \sqrt{\frac{1 - \cos x}{2}}$$

$$\cos\left(\frac{x}{2}\right) = \sqrt{\frac{1 + \cos x}{2}}$$

$$\tan\left(\frac{x}{2}\right) = \sqrt{\frac{1 - \cos x}{1 + \cos x}} = \frac{\sin x}{1 + \cos x} = \frac{1 - \cos x}{\sin x}$$

**INVERSE TRIGONOMETRIC FUNCTIONS**

$y = \sin^{-1} x = \arcsin x$  is the angle  $y$  whose sine is  $x$ .

**Example**  $y = \sin^{-1} \frac{1}{2}$ ,  $y$  is  $30^\circ$ .

The complete solution of the equation  $x = \sin y$  is  $y = (-1)^n \sin^{-1} x + n(180^\circ)$ ,  $-\pi/2 \leq \sin^{-1} x \leq \pi/2$  where  $\sin^{-1} x$  is the principal value of the angle whose sine is  $x$ . The range of principal values of the  $\cos^{-1} x$  is  $0 \leq \cos^{-1} x \leq \pi$  and  $-\pi/2 \leq \tan^{-1} x \leq \pi/2$ . If these restrictions are allowed to hold, the following formulas result:

$$\sin^{-1} x = \cos^{-1} \sqrt{1 - x^2} = \tan^{-1} \frac{x}{\sqrt{1 - x^2}} = \cot^{-1} \frac{\sqrt{1 - x^2}}{x}$$

$$= \sec^{-1} \frac{1}{\sqrt{1 - x^2}} = \csc^{-1} \frac{1}{x} = \frac{\pi}{2} - \cos^{-1} x$$

$$\cos^{-1} x = \sin^{-1} \sqrt{1 - x^2} = \tan^{-1} \frac{\sqrt{1 - x^2}}{x}$$

$$= \cot^{-1} \frac{x}{\sqrt{1 - x^2}} = \sec^{-1} \frac{1}{x}$$

$$= \csc^{-1} \frac{1}{\sqrt{1 - x^2}} = \frac{\pi}{2} - \sin^{-1} x$$

$$\tan^{-1} x = \sin^{-1} \frac{x}{\sqrt{1 + x^2}} = \cos^{-1} \frac{1}{\sqrt{1 + x^2}}$$

$$= \cot^{-1} \frac{1}{x} = \sec^{-1} \sqrt{1 + x^2} = \csc^{-1} \frac{\sqrt{1 + x^2}}{x}$$

**RELATIONS BETWEEN ANGLES AND SIDES OF TRIANGLES**

**Solutions of Triangles** (Fig. 3-42) Let  $a, b, c$  denote the sides and  $\alpha, \beta, \gamma$  the angles opposite the sides in the triangle. Let  $2s = a +$

FIG. 3-42 Triangle.

$b + c$ ,  $A = \text{area}$ ,  $r = \text{radius of the inscribed circle}$ ,  $R = \text{radius of the circumscribed circle}$ , and  $h = \text{altitude}$ . In any triangle  $\alpha + \beta + \gamma = 180^\circ$ .

**Law of Sines**  $\sin \alpha/a = \sin \beta/b = \sin \gamma/c = 1/(2R)$ .

**Law of Tangents**

$$\frac{a + b}{a - b} = \frac{\tan \frac{1}{2}(\alpha + \beta)}{\tan \frac{1}{2}(\alpha - \beta)}; \frac{b + c}{b - c} = \frac{\tan \frac{1}{2}(\beta + \gamma)}{\tan \frac{1}{2}(\beta - \gamma)}; \frac{a + c}{a - c} = \frac{\tan \frac{1}{2}(\alpha + \gamma)}{\tan \frac{1}{2}(\alpha - \gamma)}$$

**Law of Cosines**  $a^2 = b^2 + c^2 - 2bc \cos \alpha$ ;  $b^2 = a^2 + c^2 - 2ac \cos \beta$ ;  $c^2 = a^2 + b^2 - 2ab \cos \gamma$ .

**Other Relations** In this subsection, where appropriate, two more formulas can be generated by replacing  $a$  by  $b$ ,  $b$  by  $c$ ,  $c$  by  $a$ ,  $\alpha$  by  $\beta$ ,  $\beta$  by  $\gamma$ , and  $\gamma$  by  $\alpha$ .  $\cos \alpha = \frac{b^2 + c^2 - a^2}{2bc}$ ;  $a = b \cos \gamma + c \cos \beta$ ;  $\sin \alpha = \frac{(2/bc) \sqrt{s(s-a)(s-b)(s-c)}}$ ;

$$\sin\left(\frac{\alpha}{2}\right) = \sqrt{\frac{(s-b)(s-c)}{bc}}; \cos\left(\frac{\alpha}{2}\right) = \sqrt{\frac{s(s-a)}{bc}}$$

$$A = \frac{1}{2} bh = \frac{1}{2} ab \sin \gamma = \frac{a^2 \sin \beta \sin \gamma}{2 \sin \alpha} = \sqrt{s(s-a)(s-b)(s-c)} = rs$$

where  $r = \sqrt{\frac{(s-a)(s-b)(s-c)}{s}}$

$$R = a/(2 \sin \alpha) = abc/4A; h = c \sin a = a \sin \gamma = 2rs/b.$$

**Right Triangle** (Fig. 3-43) Given one side and any acute angle  $\alpha$  or any two sides, the remaining parts can be obtained from the following formulas:

$$a = \sqrt{(c+b)(c-b)} = c \sin \alpha = b \tan \alpha$$

$$b = \sqrt{(c+a)(c-a)} = c \cos \alpha = a \cot \alpha$$

$$c = \sqrt{a^2 + b^2}, \sin \alpha = \frac{a}{c}, \cos \alpha = \frac{b}{c}, \tan \alpha = \frac{a}{b}, \beta = 90^\circ - \alpha$$

$$A = \frac{1}{2} ab = \frac{a^2}{2 \tan \alpha} = \frac{b^2 \tan \alpha}{2} = \frac{c^2 \sin 2\alpha}{4}$$

**Oblique Triangles** (Fig. 3-44) There are four possible cases.

1. Given  $b, c$  and the included angles  $\alpha$ ,

$$\frac{1}{2}(\beta + \gamma) = 90^\circ - \frac{1}{2}\alpha; \tan \frac{1}{2}(\beta - \gamma) = \frac{b - c}{b + c} \tan \frac{1}{2}(\beta + \gamma)$$

$$\beta = \frac{1}{2}(\beta + \gamma) + \frac{1}{2}(\beta - \gamma); \gamma = \frac{1}{2}(\beta + \gamma) - \frac{1}{2}(\beta - \gamma); a = \frac{b \sin \alpha}{\sin \beta}$$

FIG. 3-43 Right triangle.

FIG. 3-44 Oblique triangle.

### 3-18 MATHEMATICS

2. Given the three sides  $a, b, c, s = \frac{1}{2}(a + b + c)$ ;

$$r = \sqrt{\frac{(s-a)(s-b)(s-c)}{s}}$$

$$\tan \frac{1}{2} \alpha = \frac{r}{s-a}; \tan \frac{1}{2} \beta = \frac{r}{s-b}; \tan \frac{1}{2} \gamma = \frac{r}{s-c}$$

3. Given any two sides  $a, c$  and an angle opposite one of them  $\alpha, \sin \gamma = (c \sin \alpha)/a; \beta = 180^\circ - a - \gamma; b = (a \sin \beta)/(\sin \alpha)$ . There may be two solutions here.  $\gamma$  may have two values  $\gamma_1, \gamma_2; \gamma_1 < 90^\circ, \gamma_2 = 180^\circ - \gamma_1 > 90^\circ$ . If  $\alpha + \gamma_2 > 180^\circ$ , use only  $\gamma_1$ . This case may be *impossible* if  $\sin \gamma > 1$ .

4. Given any side  $c$  and two angles  $\alpha$  and  $\beta, \gamma = 180^\circ - \alpha - \beta; a = (c \sin \alpha)/(\sin \gamma); b = (c \sin \beta)/(\sin \gamma)$ .

### HYPERBOLIC TRIGONOMETRY

The hyperbolic functions are certain combinations of exponentials  $e^x$  and  $e^{-x}$ .

$$\cosh x = \frac{e^x + e^{-x}}{2}; \sinh x = \frac{e^x - e^{-x}}{2}; \tanh x = \frac{\sinh x}{\cosh x} = \frac{e^x - e^{-x}}{e^x + e^{-x}}$$

$$\coth x = \frac{e^x + e^{-x}}{e^x - e^{-x}} = \frac{1}{\tanh x} = \frac{\cosh x}{\sinh x}; \operatorname{sech} x = \frac{1}{\cosh x} = \frac{2}{e^x + e^{-x}};$$

$$\operatorname{csch} x = \frac{1}{\sinh x} = \frac{2}{e^x - e^{-x}}$$

**Fundamental Relationships**  $\sinh x + \cosh x = e^x; \cosh x - \sinh x = e^{-x}; \cosh^2 x - \sinh^2 x = 1; \operatorname{sech}^2 x + \tanh^2 x = 1; \coth^2 x - \operatorname{csch}^2 x = 1; \sinh 2x = 2 \sinh x \cosh x; \cosh 2x = \cosh^2 x + \sinh^2 x = 1 + 2 \sinh^2 x = 2 \cosh^2 x - 1. \tanh 2x = (2 \tanh x)/(1 + \tanh^2 x); \sinh(x \pm y) = \sinh x \cosh y \pm \cosh x \sinh y;$

$\cosh y \pm \cosh x \sinh y; \cosh(x \pm y) = \cosh x \cosh y \pm \sinh x \sinh y; 2 \sinh^2 x/2 = \cosh x - 1; 2 \cosh^2 x/2 = \cosh x + 1; \sinh(-x) = -\sinh x; \cosh(-x) = \cosh x; \tanh(-x) = -\tanh x.$

When  $u = a \cosh x, v = a \sinh x$ , then  $u^2 - v^2 = a^2$ ; which is the equation for a hyperbola. In other words, the hyperbolic functions in the parametric equations  $u = a \cosh x, v = a \sinh x$  have the same relation to the hyperbola  $u^2 - v^2 = a^2$  that the equations  $u = a \cos \theta, v = a \sin \theta$  have to the circle  $u^2 + v^2 = a^2$ .

**Inverse Hyperbolic Functions** If  $x = \sinh y$ , then  $y$  is the inverse hyperbolic sine of  $x$  written  $y = \sinh^{-1} x$  or  $\operatorname{arsinh} x. \sinh^{-1} x = \log_e(x + \sqrt{x^2 + 1})$

$$\cosh^{-1} x = \log_e(x + \sqrt{x^2 - 1}); \tanh^{-1} x = \frac{1}{2} \log_e \frac{1+x}{1-x};$$

$$\operatorname{coth}^{-1} x = \frac{1}{2} \log_e \frac{x+1}{x-1}; \operatorname{sech}^{-1} x = \log_e \left( \frac{1 + \sqrt{1-x^2}}{x} \right);$$

$$\operatorname{csch}^{-1} x = \log_e \left( \frac{1 + \sqrt{1+x^2}}{x} \right)$$

**Magnitude of the Hyperbolic Functions**  $\cosh x \geq 1$  with equality only for  $x = 0; -\infty < \sinh x < \infty; -1 < \tanh x < 1. \cosh x \sim e^{x/2}$  as  $x \rightarrow \infty; \sinh x \rightarrow e^{x/2}$  as  $x \rightarrow \infty.$

### APPROXIMATIONS FOR TRIGONOMETRIC FUNCTIONS

For small values of  $\theta$  ( $\theta$  measured in radians)  $\sin \theta \approx \theta, \tan \theta \approx \theta; \cos \theta \approx 1 - (\theta^2/2)$ . The behavior ratio of the functions as  $\theta \rightarrow 0$  is given by the following:

$$\lim_{\theta \rightarrow 0} \sin \theta / \theta = 1; \sin \theta / \tan \theta = 1.$$

## DIFFERENTIAL AND INTEGRAL CALCULUS

**REFERENCES:** Char, B. W., et al., *Maple V Language Reference Manual*, Springer-Verlag, New York (1991); Wolfram, S., *The Mathematics Book*, 5th ed., Wolfram Media (2003).

### DIFFERENTIAL CALCULUS

**An Example of Functional Notation** Suppose that a storage warehouse of 16,000 ft<sup>3</sup> is required. The construction costs per square foot are \$10, \$3, and \$2 for walls, roof, and floor respectively. What are the minimum cost dimensions? Thus, with  $h =$  height,  $x =$  width, and  $y =$  length, the respective costs are

$$\text{Walls} = 2 \times 10hy + 2 \times 10hx = 20h(y + x)$$

$$\text{Roof} = 3xy$$

$$\text{Floor} = 2xy$$

$$\text{Total cost} = 2xy + 3xy + 20h(x + y) = 5xy + 20h(x + y) \quad (3-1)$$

and the restriction

$$\text{Total volume} = xyh \quad (3-2)$$

Solving for  $h$  from Eq. (3-2),

$$h = \text{volume}/xy = 16,000/xy \quad (3-3)$$

$$\text{Cost} = 5xy + \frac{320,000}{xy}(y + x) = 5xy + 320,000 \left( \frac{1}{x} + \frac{1}{y} \right) \quad (3-4)$$

In this form it can be shown that the minimum cost will occur for  $x = y$ ; therefore

$$\text{Cost} = 5x^2 + 640,000(1/x)$$

By evaluation, the smallest cost will occur when  $x = 40$ .

$$\text{Cost} = 5(1600) + 640,000/40 = \$24,000$$

The dimensions are then  $x = 40$  ft,  $y = 40$  ft,  $h = 16,000/(40 \times 40) = 10$  ft. Symbolically, the original cost relationship is written

$$\text{Cost} = f(x, y, h) = 5xy + 20h(y + x)$$

and the volume relation

$$\text{Volume} = g(x, y, h) = xyh = 16,000$$

In terms of the derived general relationships (3-1) and (3-2),  $x, y$ , and  $h$  are **independent variables**—cost and volume, **dependent variables**. That is, the cost and volume become fixed with the specification of dimensions. However, corresponding to the given restriction of the problem, relative to volume, the function  $g(x, y, z) = xyh$  becomes a constraint function. In place of three independent and two dependent variables the problem reduces to two independent (volume has been constrained) and two dependent as in functions (3-3) and (3-4). Further, the requirement of minimum cost reduces the problem to three dependent variables ( $x, y, h$ ) and no **degrees of freedom**, that is, freedom of independent selection.

**Limits** The limit of function  $f(x)$  as  $x$  approaches  $a$  ( $a$  is finite or else  $x$  is said to increase without bound) is the number  $N$ .

$$\lim_{x \rightarrow a} f(x) = N$$

This states that  $f(x)$  can be calculated as close to  $N$  as desirable by making  $x$  sufficiently close to  $a$ . This does not put any restriction on  $f(x)$  when  $x = a$ . Alternatively, for any given positive number  $\epsilon$ , a number  $\delta$  can be found such that  $0 < |a - x| < \delta$  implies that  $|N - f(x)| < \epsilon$ .

The following operations with limits (when they exist) are valid:

$$\lim_{x \rightarrow a} bf(x) = b \lim_{x \rightarrow a} f(x)$$

$$\lim_{x \rightarrow a} [f(x) + g(x)] = \lim_{x \rightarrow a} f(x) + \lim_{x \rightarrow a} g(x)$$

$$\lim_{x \rightarrow a} [f(x)g(x)] = \lim_{x \rightarrow a} f(x) \cdot \lim_{x \rightarrow a} g(x)$$

$$\lim_{x \rightarrow a} \frac{f(x)}{g(x)} = \frac{\lim_{x \rightarrow a} f(x)}{\lim_{x \rightarrow a} g(x)} \quad \text{if } \lim_{x \rightarrow a} g(x) \neq 0$$

See “Indeterminant Forms” below when  $g(a) = 0$ .  
**Continuity** A function  $f(x)$  is continuous at the point  $x = a$  if

$$\lim_{h \rightarrow 0} [f(a+h) - f(a)] = 0$$

Rigorously, it is stated  $f(x)$  is continuous at  $x = a$  if for any positive  $\epsilon$  there exists a  $\delta > 0$  such that  $|f(a+h) - f(a)| < \epsilon$  for all  $x$  with  $|x - a| < \delta$ . For example, the function  $(\sin x)/x$  is not continuous at  $x = 0$  and therefore is said to be discontinuous. Discontinuities are classified into three types:

1. Removable  $y = \sin x/x$  at  $x = 0$
2. Infinite  $y = 1/x$  at  $x = 0$
3. Jump  $y = 10/(1 + e^{1/x})$  at  $x = 0^+$   $y = 0^+$   
 $x = 0$   $y = 0$   
 $x = 0^-$   $y = 10$

**Derivative** The function  $f(x)$  has a derivative at  $x = a$ , which can be denoted as  $f'(a)$ , if

$$\lim_{h \rightarrow 0} \frac{f(a+h) - f(a)}{h}$$

exists. This implies continuity at  $x = a$ . Conversely, a function may be continuous but not have a derivative. The derivative function is

$$f'(x) = \frac{df}{dx} = \lim_{h \rightarrow 0} \frac{f(x+h) - f(x)}{h}$$

**Differentiation** Define  $\Delta y = f(x + \Delta x) - f(x)$ . Then dividing by  $\Delta x$

$$\frac{\Delta y}{\Delta x} = \frac{f(x + \Delta x) - f(x)}{\Delta x}$$

Call  $\lim_{\Delta x \rightarrow 0} \frac{\Delta y}{\Delta x} = \frac{dy}{dx}$

then  $\frac{dy}{dx} = \lim_{\Delta x \rightarrow 0} \frac{f(x + \Delta x) - f(x)}{\Delta x}$

**Example** Find the derivative of  $y = \sin x$ .

$$\begin{aligned} \frac{dy}{dx} &= \lim_{\Delta x \rightarrow 0} \frac{\sin(x + \Delta x) - \sin(x)}{\Delta x} \\ &= \lim_{\Delta x \rightarrow 0} \frac{\sin x \cos \Delta x + \sin \Delta x \cos x - \sin x}{\Delta x} \\ &= \lim_{\Delta x \rightarrow 0} \frac{\sin x(\cos \Delta x - 1)}{\Delta x} + \lim_{\Delta x \rightarrow 0} \frac{\sin \Delta x \cos x}{\Delta x} \\ &= \cos x \text{ since } \lim_{\Delta x \rightarrow 0} \frac{\sin \Delta x}{\Delta x} = 1 \end{aligned}$$

**Differential Operations** The following differential operations are valid:  $f, g, \dots$  are differentiable functions of  $x$ ,  $c$  and  $n$  are constants;  $e$  is the base of the natural logarithms.

$$\frac{dc}{dx} = 0 \tag{3-5}$$

$$\frac{dx}{dx} = 1 \tag{3-6}$$

$$\frac{d}{dx}(f + g) = \frac{df}{dx} + \frac{dg}{dx} \tag{3-7}$$

$$\frac{d}{dx}(f \times g) = f \frac{dg}{dx} + g \frac{df}{dx} \tag{3-8}$$

$$\frac{dy}{dx} = \frac{1}{dx/dy} \quad \text{if } \frac{dx}{dy} \neq 0 \tag{3-9}$$

$$\frac{d}{dx} f^n = n f^{n-1} \frac{df}{dx} \tag{3-10}$$

$$\frac{d}{dx} \left( \frac{f}{g} \right) = \frac{g(df/dx) - f(dg/dx)}{g^2} \tag{3-11}$$

$$\frac{df}{dx} = \frac{df}{dv} \times \frac{dv}{dx} \quad (\text{chain rule}) \tag{3-12}$$

$$\frac{df^g}{dx} = g f^{g-1} \frac{df}{dx} + f^g \ln f \frac{dg}{dx} \tag{3-13}$$

$$\frac{da^x}{dx} = (\ln a) a^x \tag{3-14}$$

**Example** Derive  $dy/dx$  for  $x^2 + y^3 = x + xy + A$ .

Here  $\frac{d}{dx} x^2 + \frac{d}{dx} y^3 = \frac{d}{dx} x + \frac{d}{dx} xy + \frac{d}{dx} A$

$$2x + 3y^2 \frac{dy}{dx} = 1 + y + x \frac{dy}{dx} + 0$$

by rules (3-10), (3-10), (3-6), (3-8), and (3-5) respectively.

Thus  $\frac{dy}{dx} = \frac{2x - 1 - y}{x - 3y^2}$

**Differentials**

$$de^x = e^x dx \tag{3-15a}$$

$$d(a^x) = a^x \log a dx \tag{3-15b}$$

$$d \ln x = (1/x) dx \tag{3-16}$$

$$d \log x = (\log e/x) dx \tag{3-17}$$

$$d \sin x = \cos x dx \tag{3-18}$$

$$d \cos x = -\sin x dx \tag{3-19}$$

$$d \tan x = \sec^2 x dx \tag{3-20}$$

$$d \cot x = -\csc^2 x dx \tag{3-21}$$

$$d \sec x = \tan x \sec x dx \tag{3-22}$$

$$d \csc x = -\cot x \csc x dx \tag{3-23}$$

$$d \sin^{-1} x = (1 - x^2)^{-1/2} dx \tag{3-24}$$

$$d \cos^{-1} x = -(1 - x^2)^{-1/2} dx \tag{3-25}$$

$$d \tan^{-1} x = (1 + x^2)^{-1} dx \tag{3-26}$$

$$d \cot^{-1} x = -(1 + x^2)^{-1} dx \tag{3-27}$$

$$d \sec^{-1} x = x^{-1}(x^2 - 1)^{-1/2} dx \tag{3-28}$$

$$d \csc^{-1} x = -x^{-1}(x^2 - 1)^{-1/2} dx \tag{3-29}$$

$$d \sinh x = \cosh x dx \tag{3-30}$$

$$d \cosh x = \sinh x dx \tag{3-31}$$

$$d \tanh x = \text{sech}^2 x dx \tag{3-32}$$

$$d \coth x = -\text{csch}^2 x dx \tag{3-33}$$

$$d \text{sech } x = -\text{sech } x \tanh x dx \tag{3-34}$$

$$d \text{csch } x = -\text{csch } x \coth x dx \tag{3-35}$$

$$d \sinh^{-1} x = (x^2 + 1)^{-1/2} dx \tag{3-36}$$

$$d \cosh^{-1} x = (x^2 - 1)^{-1/2} dx \tag{3-37}$$

$$d \tanh^{-1} x = (1 - x^2)^{-1} dx \tag{3-38}$$

$$d \coth^{-1} x = -(x^2 - 1)^{-1} dx \tag{3-39}$$

$$d \text{sech}^{-1} x = -(1/x)(1 - x^2)^{-1/2} dx \tag{3-40}$$

$$d \text{csch}^{-1} x = -x^{-1}(x^2 + 1)^{-1/2} dx \tag{3-41}$$

### 3-20 MATHEMATICS

**Example** Find  $dy/dx$  for  $y = \sqrt{x} \cos(1-x^2)$ . Using

$$\frac{dy}{dx} = \sqrt{x} \frac{d}{dx} \cos(1-x^2) + \cos(1-x^2) \frac{d}{dx} \sqrt{x} \quad (3-8)$$

$$\begin{aligned} \frac{d}{dx} \cos(1-x^2) &= -\sin(1-x^2) \frac{d}{dx} (1-x^2) \\ &= -\sin(1-x^2)(0-2x) \end{aligned} \quad (3-19) \quad (3-5), (3-10)$$

$$\frac{d\sqrt{x}}{dx} = \frac{1}{2} x^{-1/2} \quad (3-10)$$

$$\frac{dy}{dx} = 2x^{3/2} \sin(1-x^2) + \frac{1}{2} x^{-1/2} \cos(1-x^2)$$

**Example** Find the derivative of  $\tan x$  with respect to  $\sin x$ .

$$\begin{aligned} v &= \sin x \\ y &= \tan x \\ \frac{d \tan x}{d \sin x} &= \frac{dy}{dv} = \frac{dy}{dx} \frac{dx}{dv} \\ &= \frac{d \tan x}{dx} \frac{1}{\frac{d \sin x}{dx}} \\ &= \sec^2 x / \cos x \end{aligned} \quad (3-12) \quad (3-9) \quad (3-18), (3-20)$$

Very often in experimental sciences and engineering functions and their derivatives are available only through their numerical values. In particular, through measurements we may know the values of a function and its derivative only at certain points. In such cases the preceding operational rules for derivatives, including the chain rule, can be applied numerically.

**Example** Given the following table of values for differentiable functions  $f$  and  $g$ ; evaluate the following quantities:

| $x$ | $f(x)$ | $f'(x)$ | $g(x)$ | $g'(x)$ |
|-----|--------|---------|--------|---------|
| 1   | 3      | 1       | 4      | -4      |
| 3   | 0      | 2       | 4      | 7       |
| 4   | -2     | 10      | 3      | 6       |

$$\frac{d}{dx} [f(x) + g(x)]_{x=4} = f'(4) + g'(4) = 10 + 6 = 16$$

$$\left(\frac{f}{g}\right)'(1) = \frac{f'(1)g(1) - f(1)g'(1)}{[g(1)]^2} = \frac{1 \cdot 4 - 3(-4)}{(4)^2} = \frac{16}{16} = 1$$

**Higher Differentials** The first derivative of  $f(x)$  with respect to  $x$  is denoted by  $f'$  or  $df/dx$ . The derivative of the first derivative is called the second derivative of  $f(x)$  with respect to  $x$  and is denoted by  $f''$ ,  $f^{(2)}$ , or  $d^2f/dx^2$ ; and similarly for the higher-order derivatives.

**Example** Given  $f(x) = 3x^3 + 2x + 1$ , calculate all derivative values at  $x = 3$ .

$$\frac{df(x)}{dx} = 9x^2 + 2 \quad x = 3, f'(3) = 9(9) + 2 = 83$$

$$\frac{d^2f(x)}{dx^2} = 18x \quad x = 3, f''(3) = 18(3) = 54$$

$$\frac{d^3f(x)}{dx^3} = 18 \quad x = 3, f'''(3) = 18$$

$$\frac{d^nf(x)}{dx^n} = 0 \quad \text{for } n \geq 4$$

If  $f'(x) > 0$  on  $(a, b)$ , then  $f$  is increasing on  $(a, b)$ . If  $f'(x) < 0$  on  $(a, b)$ , then  $f$  is decreasing on  $(a, b)$ .

The graph of a function  $y = f(x)$  is concave up if  $f'$  is increasing on  $(a, b)$ ; it is concave down if  $f'$  is decreasing on  $(a, b)$ .

If  $f''(x)$  exists on  $(a, b)$  and if  $f''(x) > 0$ , then  $f$  is concave up on  $(a, b)$ . If  $f''(x) < 0$ , then  $f$  is concave down on  $(a, b)$ .

An inflection point is a point at which a function changes the direction of its concavity.

**Indeterminate Forms: L'Hospital's Theorem** Forms of the type  $0/0$ ,  $\infty/\infty$ ,  $0 \times \infty$ , etc., are called indeterminates. To find the limiting values that the corresponding functions approach, L'Hospital's theorem is useful: If two functions  $f(x)$  and  $g(x)$  both become zero at  $x = a$ , then the limit of their quotient is equal to the limit of the quotient of their separate derivatives, if the limit exists, or is  $+\infty$  or  $-\infty$ .

**Example** Find  $\lim_{x \rightarrow 0} \frac{\sin x}{x}$ .

Here 
$$\lim_{x \rightarrow 0} \frac{\sin x}{x} = \lim_{x \rightarrow 0} \frac{d \sin x}{dx} = \lim_{x \rightarrow 0} \frac{\cos x}{1} = 1$$

**Example** Find  $\lim_{x \rightarrow \infty} \frac{(1.1)^x}{x^{1000}}$ .

$$\lim_{x \rightarrow \infty} \frac{(1.1)^x}{x^{1000}} = \lim_{x \rightarrow \infty} \frac{d(1.1)^x}{dx^{1000}} = \lim_{x \rightarrow \infty} \frac{(\ln 1.1)(1.1)^x}{1000x^{999}}$$

Obviously  $\lim_{x \rightarrow \infty} \frac{1.1^x}{x^{1000}} = \infty$  since repeated application of the rule will reduce the denominator to a finite number 1000! while the numerator remains infinitely large.

**Example** Find  $\lim_{x \rightarrow \infty} x^3 e^{-x}$ .

$$\lim_{x \rightarrow \infty} x^3 e^{-x} = \lim_{x \rightarrow \infty} \frac{x^3}{e^x} = \lim_{x \rightarrow \infty} \frac{6}{e^x} = 0$$

**Example** Find  $\lim_{x \rightarrow 0} (1-x)^{1/x}$ .

Let 
$$y = (1-x)^{1/x}$$
  

$$\ln y = (1/x) \ln(1-x)$$
  

$$\lim_{x \rightarrow 0} (\ln y) = \lim_{x \rightarrow 0} \frac{\ln(1-x)}{x} = -1$$

Therefore, 
$$\lim_{x \rightarrow 0} y = e^{-1}$$

**Partial Derivative** The abbreviation  $z = f(x, y)$  means that  $z$  is a function of the two variables  $x$  and  $y$ . The derivative of  $z$  with respect to  $x$ , treating  $y$  as a constant, is called the partial derivative with respect to  $x$  and is usually denoted as  $\partial z/\partial x$  or  $\partial f(x, y)/\partial x$  or simply  $f_x$ . Partial differentiation, like full differentiation, is quite simple to apply. Conversely, the solution of partial differential equations is appreciably more difficult than that of differential equations.

**Example** Find  $\partial z/\partial x$  and  $\partial z/\partial y$  for  $z = ye^{x^2} + xe^y$ .

$$\begin{aligned} \frac{\partial z}{\partial x} &= y \frac{\partial e^{x^2}}{\partial x} + e^y \frac{\partial x}{\partial x} & \frac{\partial z}{\partial y} &= e^{x^2} \frac{\partial y}{\partial y} + x \frac{\partial e^y}{\partial y} \\ &= 2xye^{x^2} + e^y & &= e^{x^2} + xe^y \end{aligned}$$

**Order of Differentiation** It is generally true that the order of differentiation is immaterial for any number of differentiations or variables provided the function and the appropriate derivatives are continuous. For  $z = f(x, y)$  it follows:

$$\frac{\partial^2 f}{\partial y^2 \partial x} = \frac{\partial^2 f}{\partial y \partial x \partial y} = \frac{\partial^2 f}{\partial x \partial y^2}$$

**General Form for Partial Differentiation**

1. Given  $f(x, y) = 0$  and  $x = g(t)$ ,  $y = h(t)$ .

Then 
$$\frac{df}{dt} = \frac{\partial f}{\partial x} \frac{dx}{dt} + \frac{\partial f}{\partial y} \frac{dy}{dt}$$

$$\begin{aligned} \frac{d^2f}{dt^2} &= \frac{\partial^2 f}{\partial x^2} \left(\frac{dx}{dt}\right)^2 + 2 \frac{\partial^2 f}{\partial x \partial y} \frac{dx}{dt} \frac{dy}{dt} + \frac{\partial^2 f}{\partial y^2} \left(\frac{dy}{dt}\right)^2 + \frac{\partial f}{\partial x} \frac{d^2x}{dt^2} \\ &\quad + \frac{\partial f}{\partial y} \frac{d^2y}{dt^2} \end{aligned}$$

**Example** Find  $df/dt$  for  $f = xy$ ,  $x = \rho \sin t$ ,  $y = \rho \cos t$ .

$$\begin{aligned} \frac{df}{dt} &= \frac{\partial(xy)}{\partial x} \left( \frac{d \rho \sin t}{dt} \right) + \frac{\partial(xy)}{\partial y} \left( \frac{d \rho \cos t}{dt} \right) \\ &= y(\rho \cos t) + x(-\rho \sin t) \\ &= \rho^2 \cos^2 t - \rho^2 \sin^2 t \end{aligned}$$

2. Given  $f(x, y) = 0$  and  $x = g(t, s)$ ,  $y = h(t, s)$ .

Then

$$\begin{aligned} \frac{\partial f}{\partial t} &= \frac{\partial f}{\partial x} \frac{\partial x}{\partial t} + \frac{\partial f}{\partial y} \frac{\partial y}{\partial t} \\ \frac{\partial f}{\partial s} &= \frac{\partial f}{\partial x} \frac{\partial x}{\partial s} + \frac{\partial f}{\partial y} \frac{\partial y}{\partial s} \end{aligned}$$

**Differentiation of Composite Function**

**Rule 1.** Given  $f(x, y) = 0$ , then  $\frac{dy}{dx} = - \frac{\partial f/\partial x}{\partial f/\partial y}$  ( $\frac{\partial f}{\partial y} \neq 0$ ).

**Rule 2.** Given  $f(u) = 0$  where  $u = g(x)$ , then

$$\begin{aligned} \frac{df}{dx} &= f'(u) \frac{du}{dx} \\ \frac{d^2f}{dx^2} &= f''(u) \left( \frac{du}{dx} \right)^2 + f'(u) \frac{d^2u}{dx^2} \end{aligned}$$

**Example** Find  $df/dx$  for  $f = \sin^2 u$  and  $u = \sqrt{1-x^2}$

$$\begin{aligned} \frac{df}{dx} &= \frac{d \sin^2 u}{du} \frac{d\sqrt{1-x^2}}{dx} \\ &= 2 \sin u \cos u \left( \frac{1}{2} \right) (-2x)(1-x^2)^{-1/2} \\ &= -2 \frac{\sqrt{1-u^2}}{u} \sin u \cos u \end{aligned}$$

**Rule 3.** Given  $f(u) = 0$  where  $u = g(x, y)$ , then

$$\begin{aligned} \frac{\partial f}{\partial x} &= f'(u) \frac{\partial u}{\partial x} \quad \frac{\partial f}{\partial y} = f'(u) \frac{\partial u}{\partial y} \\ \frac{\partial^2 f}{\partial x^2} &= f'' \left( \frac{\partial u}{\partial x} \right)^2 + f' \frac{\partial^2 u}{\partial x^2} \\ \frac{\partial^2 f}{\partial x \partial y} &= f'' \frac{\partial u}{\partial x} \frac{\partial u}{\partial y} + f' \frac{\partial^2 u}{\partial x \partial y} \\ \frac{\partial^2 f}{\partial y^2} &= f'' \left( \frac{\partial u}{\partial y} \right)^2 + f' \frac{\partial^2 u}{\partial y^2} \end{aligned}$$

**MULTIVARIABLE CALCULUS APPLIED TO THERMODYNAMICS**

Many of the functional relationships needed in thermodynamics are direct applications of the rules of multivariable calculus. This section reviews those rules in the context of the needs of thermodynamics. These ideas were expounded in one of the classic books on chemical engineering thermodynamics [see Hougen, O. A., et al., Part II, "Thermodynamics," in *Chemical Process Principles*, 2d ed., Wiley, New York (1959)].

**State Functions** State functions depend only on the state of the system, not on past history or how one got there. If  $z$  is a function of two variables,  $x$  and  $y$ , then  $z(x, y)$  is a state function, since  $z$  is known once  $x$  and  $y$  are specified. The differential of  $z$  is

$$dz = M dx + N dy$$

The line integral

$$\int_C (M dx + N dy)$$

is independent of the path in  $x$ - $y$  space if and only if

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x} \tag{3-42}$$

The total differential can be written as

$$dz = \left( \frac{\partial z}{\partial x} \right)_y dx + \left( \frac{\partial z}{\partial y} \right)_x dy \tag{3-43}$$

and the following condition guarantees path independence.

$$\frac{\partial}{\partial y} \left( \frac{\partial z}{\partial x} \right)_y = \frac{\partial}{\partial x} \left( \frac{\partial z}{\partial y} \right)_x$$

or

$$\frac{\partial^2 z}{\partial y \partial x} = \frac{\partial^2 z}{\partial x \partial y} \tag{3-44}$$

**Example** Suppose  $z$  is constant and apply Eq. (3-43).

$$\left[ 0 = \left( \frac{\partial z}{\partial x} \right)_y dx + \left( \frac{\partial z}{\partial y} \right)_x dy \right]_z$$

Rearrangement gives

$$\left( \frac{\partial z}{\partial x} \right)_y = - \left( \frac{\partial y}{\partial x} \right)_z \left( \frac{\partial z}{\partial y} \right)_x = - \frac{(\partial y/\partial x)_z}{(\partial y/\partial z)_x} \tag{3-45}$$

Alternatively, divide Eq. (3-43) by  $dy$  when holding some other variable  $w$  constant to obtain

$$\left( \frac{\partial z}{\partial x} \right)_w = \left( \frac{\partial z}{\partial x} \right)_y \left( \frac{\partial x}{\partial y} \right)_w + \left( \frac{\partial z}{\partial y} \right)_x \tag{3-46}$$

Also divide both numerator and denominator of a partial derivative by  $dw$  while holding a variable  $y$  constant to get

$$\left( \frac{\partial z}{\partial x} \right)_y = \frac{(\partial z/\partial w)_y}{(\partial x/\partial w)_y} = \left( \frac{\partial z}{\partial w} \right)_y \left( \frac{\partial w}{\partial x} \right)_y \tag{3-47}$$

**Thermodynamic State Functions** In thermodynamics, the state functions include the internal energy,  $U$ ; enthalpy,  $H$ ; and Helmholtz and Gibbs free energies,  $A$  and  $G$ , respectively, defined as follows:

$$\begin{aligned} H &= U + pV \\ A &= U - TS \\ G &= H - TS = U + pV - TS = A + pV \end{aligned}$$

$S$  is the entropy,  $T$  the absolute temperature,  $p$  the pressure, and  $V$  the volume. These are also state functions, in that the entropy is specified once two variables (like  $T$  and  $p$ ) are specified, for example. Likewise,  $V$  is specified once  $T$  and  $p$  are specified; it is therefore a state function.

All applications are for closed systems with constant mass. If a process is reversible and only  $p$ - $V$  work is done, the first law and differentials can be expressed as follows.

$$\begin{aligned} dU &= T dS - p dV \\ dH &= T dS + V dp \\ dA &= -S dT - p dV \\ dG &= -S dT + V dp \end{aligned}$$

Alternatively, if the internal energy is considered a function of  $S$  and  $V$ , then the differential is:

$$dU = \left( \frac{\partial U}{\partial S} \right)_V dS + \left( \frac{\partial U}{\partial V} \right)_S dV$$

This is the equivalent of Eq. (3-43) and gives the following definitions.

$$T = \left( \frac{\partial U}{\partial S} \right)_V, \quad p = - \left( \frac{\partial U}{\partial V} \right)_S$$

Since the internal energy is a state function, then Eq. (3-44) must be satisfied.

$$\frac{\partial^2 U}{\partial V \partial S} = \frac{\partial^2 U}{\partial S \partial V}$$

This is

$$\left( \frac{\partial T}{\partial V} \right)_S = - \left( \frac{\partial p}{\partial S} \right)_V$$

This is one of the Maxwell relations, and the other Maxwell relations can be derived in a similar fashion by applying Eq. (3-44).

See Sec. 4, Thermodynamics, "Constant-Composition Systems."

### 3-22 MATHEMATICS

**Partial Derivatives of All Thermodynamic Functions** The various partial derivatives of the thermodynamic functions can be classified into six groups. In the general formulas below, the variables  $U, H, A, G$  or  $S$  are denoted by Greek letters, while the variables  $V, T, p$  or  $p$  are denoted by Latin letters.

**Type I** (3 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial a}{\partial b}\right)_c; \text{ Specific: } \left(\frac{\partial p}{\partial T}\right)_V$$

Eq. (3-45) gives

$$\left(\frac{\partial p}{\partial T}\right)_V = -\left(\frac{\partial V}{\partial T}\right)_p \left(\frac{\partial p}{\partial V}\right)_T = -\frac{(\partial V/\partial T)_p}{(\partial V/\partial p)_T}$$

**Type II** (30 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial \alpha}{\partial b}\right)_c; \text{ Specific: } \left(\frac{\partial G}{\partial T}\right)_V$$

The differential for  $G$  gives

$$\left(\frac{\partial G}{\partial T}\right)_V = -S + V \left(\frac{\partial p}{\partial T}\right)_V$$

Using the other equations for  $U, H, A$ , or  $S$  gives the other possibilities.

**Type III** (15 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial a}{\partial b}\right)_\alpha; \text{ Specific: } \left(\frac{\partial V}{\partial T}\right)_S$$

First expand the derivative using Eq. (3-45).

$$\left(\frac{\partial V}{\partial T}\right)_S = -\left(\frac{\partial S}{\partial T}\right)_V \left(\frac{\partial V}{\partial S}\right)_T = -\frac{(\partial S/\partial T)_V}{(\partial S/\partial V)_T}$$

Then evaluate the numerator and denominator as type II derivatives.

$$\left(\frac{\partial V}{\partial T}\right)_S = -\frac{\frac{C_V}{T}}{-\left(\frac{\partial V}{\partial T}\right)_p \left(\frac{\partial p}{\partial V}\right)_T} = \frac{C_V}{T} \left(\frac{\partial p}{\partial T}\right)_p$$

These derivatives are of importance for reversible, adiabatic processes (such as in an ideal turbine or compressor), since then the entropy is constant. An example is the Joule-Thomson coefficient for constant  $H$ .

$$\left(\frac{\partial T}{\partial p}\right)_H = \frac{1}{C_p} \left[ -V + T \left(\frac{\partial V}{\partial T}\right)_p \right]$$

**Type IV** (30 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial \alpha}{\partial \beta}\right)_c; \text{ Specific: } \left(\frac{\partial G}{\partial A}\right)_p$$

Use Eq. (3-47) to introduce a new variable.

$$\left(\frac{\partial G}{\partial A}\right)_p = \left(\frac{\partial G}{\partial T}\right)_p \left(\frac{\partial T}{\partial A}\right)_p = \frac{(\partial G/\partial T)_p}{(\partial A/\partial T)_p}$$

This operation has created two type II derivatives; by substitution we obtain

$$\left(\frac{\partial G}{\partial A}\right)_p = \frac{S}{S + p (\partial V/\partial T)_p}$$

**Type V** (60 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial \alpha}{\partial b}\right)_\beta; \text{ Specific: } \left(\frac{\partial G}{\partial p}\right)_A$$

Start from the differential for  $dG$ . Then we get

$$\left(\frac{\partial G}{\partial p}\right)_A = -S \left(\frac{\partial T}{\partial p}\right)_A + V$$

The derivative is type III and can be evaluated by using Eq. (3-45).

$$\left(\frac{\partial G}{\partial p}\right)_A = S \frac{(\partial A/\partial p)_T}{(\partial A/\partial T)_p} + V$$

The two type II derivatives are then evaluated.

$$\left(\frac{\partial G}{\partial p}\right)_A = \frac{Sp (\partial V/\partial p)_T}{S + p (\partial V/\partial T)_p} + V$$

These derivatives are also of interest for free expansions or isentropic changes.

**Type VI** (30 possibilities plus reciprocals)

$$\text{General: } \left(\frac{\partial \alpha}{\partial \beta}\right)_\gamma; \text{ Specific: } \left(\frac{\partial G}{\partial A}\right)_H$$

We use Eq. (3-47) to obtain two type V derivatives.

$$\left(\frac{\partial G}{\partial A}\right)_H = \frac{(\partial G/\partial T)_H}{(\partial A/\partial T)_H}$$

These can then be evaluated using the procedures for Type V derivatives.

### INTEGRAL CALCULUS

**Indefinite Integral** If  $f'(x)$  is the derivative of  $f(x)$ , an antiderivative of  $f'(x)$  is  $f(x)$ . Symbolically, the indefinite integral of  $f'(x)$  is

$$\int f'(x) dx = f(x) + c$$

where  $c$  is an arbitrary constant to be determined by the problem. By virtue of the known formulas for differentiation the following relationships hold ( $a$  is a constant):

$$\int (du + dv + dw) = \int du + \int dv + \int dw \quad (3-48)$$

$$\int a dv = a \int dv \quad (3-49)$$

$$\int v^n dv = \frac{v^{n+1}}{n+1} + c \quad (n \neq -1) \quad (3-50)$$

$$\int \frac{dv}{v} = \ln |v| + c \quad (3-51)$$

$$\int a^v dv = \frac{a^v}{\ln a} + c \quad (3-52)$$

$$\int e^v dv = e^v + c \quad (3-53)$$

$$\int \sin v dv = -\cos v + c \quad (3-54)$$

$$\int \cos v dv = \sin v + c \quad (3-55)$$

$$\int \sec^2 v dv = \tan v + c \quad (3-56)$$

$$\int \csc^2 v dv = -\cot v + c \quad (3-57)$$

$$\int \sec v \tan v dv = \sec v + c \quad (3-58)$$

$$\int \csc v \cot v dv = -\csc v + c \quad (3-59)$$

$$\int \frac{dv}{v^2 + a^2} = \frac{1}{a} \tan^{-1} \frac{v}{a} + c \quad (3-60)$$

$$\int \frac{dv}{\sqrt{a^2 - v^2}} = \sin^{-1} \frac{v}{a} + c \quad (3-61)$$

$$\int \frac{dv}{v^2 - a^2} = \frac{1}{2a} \ln \left| \frac{v-a}{v+a} \right| + c \quad (3-62)$$

$$\int \frac{dv}{\sqrt{v^2 \pm a^2}} = \ln |v + \sqrt{v^2 \pm a^2}| + c \quad (3-63)$$

$$\int \sec v dv = \ln (\sec v + \tan v) + c \quad (3-64)$$

$$\int \csc v \, dv = \ln |\csc v - \cot v| + c \quad (3-65)$$

**Example** Find  $\int (3x^2 + e^x - 10) \, dx$  using Eq. (3-48).  $\int (3x^2 + e^x - 10) \, dx = 3 \int x^2 \, dx + \int e^x \, dx - 10 \int dx = x^3 + e^x - 10x + c$  (by Eqs. 3-50, 3-53).

**Example** Find  $\int \frac{7x \, dx}{2 - 3x^2}$ . Let  $v = 2 - 3x^2$ ;  $dv = -6x \, dx$

Thus 
$$\begin{aligned} \int \frac{7x \, dx}{2 - 3x^2} &= 7 \int \frac{x \, dx}{2 - 3x^2} = -\frac{7}{6} \int \frac{-6x \, dx}{2 - 3x^2} \\ &= -\frac{7}{6} \int \frac{dv}{v}, \text{ with } v = 2 - 3x^2 \text{ and } dv = -6x \, dx \\ &= -\frac{7}{6} \ln |v| + c = -\frac{7}{6} \ln |2 - 3x^2| + c \end{aligned}$$

**Example—Constant of Integration** By definition the derivative of  $x^3$  is  $3x^2$ , and  $x^3$  is therefore the integral of  $3x^2$ . However, if  $f = x^3 + 10$ , it follows that  $f' = 3x^2$ , and  $x^3 + 10$  is therefore also the integral of  $3x^2$ . For this reason the constant  $c$  in  $\int 3x^2 \, dx = x^3 + c$  must be determined by the problem conditions, i.e., the value of  $f$  for a specified  $x$ .

**Methods of Integration** In practice it is rare when generally encountered functions can be directly integrated. For example, the integrand in  $\int \sqrt{\sin x} \, dx$  which appears quite simple has no elementary function whose derivative is  $\sqrt{\sin x}$ . In general, there is no explicit way of determining whether a particular function can be integrated into an elementary form. As a whole, integration is a trial-and-error proposition which depends on the effort and ingenuity of the practitioner. The following are general procedures which can be used to find the elementary forms of the integral when they exist. When they do not exist or cannot be found either from tabled integration formulas or directly, the only recourse is series expansion as illustrated later. Indefinite integrals cannot be solved numerically unless they are redefined as definite integrals (see "Definite Integral"), i.e.,  $F(x) = \int f(x) \, dx$ , indefinite, whereas  $F(x) = \int_a^x f(t) \, dt$ , definite.

**Direct Formula** Many integrals can be solved by transformation in the integrand to one of the forms given previously.

**Example** Find  $\int x^2 \sqrt{3x^3 + 10} \, dx$ . Let  $v = 3x^3 + 10$  for which  $dv = 9x^2 \, dx$ . Thus

$$\begin{aligned} \int x^2 \sqrt{3x^3 + 10} \, dx &= \int (3x^3 + 10)^{1/2} (x^2 \, dx) \\ &= \frac{1}{9} \int (3x^3 + 10)^{1/2} (9x^2 \, dx) = \frac{1}{9} \int v^{1/2} \, dv \\ &= \frac{1}{9} \frac{v^{3/2}}{3/2} + c \quad [\text{by Eq. (3-50)}] \\ &= \frac{2}{27} (3x^3 + 10)^{3/2} + c \end{aligned}$$

**Trigonometric Substitution** This technique is particularly well adapted to integrands in the form of radicals. For these the function is transformed into a trigonometric form. In the latter form they may be more easily recognizable relative to the identity formulas. These functions and their transformations are

$$\begin{aligned} \sqrt{x^2 - a^2} \quad &\text{Let } x = a \sec \theta \\ \sqrt{x^2 + a^2} \quad &\text{Let } x = a \tan \theta \\ \sqrt{a^2 - x^2} \quad &\text{Let } x = a \sin \theta \end{aligned}$$

**Example** Find  $\int \frac{\sqrt{4-9x^2}}{x^2} \, dx$ . Let  $x = \frac{2}{3} \sin \theta$ ; then  $dx = \frac{2}{3} \cos \theta \, d\theta$ .

$$3 \int \frac{\sqrt{(2/3)^2 - x^2}}{x^2} \, dx = 3 \int \frac{2/3 \sqrt{1 - \sin^2 \theta}}{(2/3)^2 \sin^2 \theta} \left( \frac{2}{3} \cos \theta \, d\theta \right)$$

$$\begin{aligned} &= 3 \int \frac{\cos^2 \theta}{\sin^2 \theta} \, d\theta = 3 \int \cot^2 \theta \, d\theta \\ &= -3 \cot \theta - 3\theta + c \text{ by trigonometric transform} \\ &= -\frac{\sqrt{4-9x^2}}{x} - 3 \sin^{-1} \frac{3}{2} x + c \text{ in terms of } x \end{aligned}$$

**Algebraic Substitution** Functions containing elements of the type  $(a + bx)^{1/n}$  are best handled by the algebraic transformation  $y^n = a + bx$ .

**Example** Find  $\int \frac{x \, dx}{(3 + 4x)^{1/4}}$ . Let  $3 + 4x = y^4$ ; then  $4dx = 4y^3 \, dy$  and

$$\begin{aligned} \int \frac{x \, dx}{(3 + 4x)^{1/4}} &= \int \frac{y^4 - 3}{4} \frac{y^3 \, dy}{y} = \frac{1}{4} \int y^2(y^4 - 3) \, dy \\ &= \frac{1}{4} \frac{y^7}{7} - \frac{3}{4} \frac{y^3}{3} + c = \frac{1}{28} (3 + 4x)^{7/4} - \frac{1}{4} (3 + 4x)^{3/4} + c \end{aligned}$$

**General** The number of possible transformations one might use are unlimited. No specific overall rules can be given. Success in handling integration problems depends primarily upon experience and ingenuity. The following example illustrates the extent to which alternative approaches are possible.

**Example** Find  $\int \frac{dx}{e^x - 1}$ . Let  $e^x = y$ ; then  $e^x \, dx = dy$  or  $dx = 1/y \, dy$ .

$$\int \frac{dx}{e^x - 1} = \int \frac{(1/y) \, dy}{y - 1} = \int \frac{dy}{y^2 - y} = \ln \frac{y - 1}{y} = \ln \frac{e^x - 1}{e^x}$$

**Partial Fractions** Rational functions are of the type  $f(x)/g(x)$  where  $f(x)$  and  $g(x)$  are polynomial expressions of degrees  $m$  and  $n$  respectively. If the degree of  $f$  is higher than  $g$ , perform the algebraic division—the remainder will then be at least one degree less than the denominator. Consider the following types:

**Type 1** Reducible denominator to linear unequal factors. For example,

$$\begin{aligned} \frac{1}{x^3 - x^2 - 4x + 4} &= \frac{1}{(x + 2)(x - 2)(x - 1)} \\ &= \frac{A}{x + 2} + \frac{B}{x - 2} + \frac{C}{x - 1} \\ &= \frac{A(x - 2)(x - 1) + B(x + 2)(x - 1) + C(x + 2)(x - 2)}{(x + 2)(x - 2)(x - 1)} \\ &= \frac{x^2(A + B + C) + x(-3A + B) + (2A - 2B - 4C)}{(x + 2)(x - 2)(x - 1)} \end{aligned}$$

Equate coefficients and solve for  $A$ ,  $B$ , and  $C$ .

$$\begin{aligned} A + B + C &= 0 \\ -3A + B &= 0 \\ 2A - 2B - 4C &= 1 \\ A = 1/2, B = 1/4, C = -1/4 \end{aligned}$$

$$\frac{1}{x^3 - x^2 - 4x + 4} = \frac{1}{12(x + 2)} + \frac{1}{4(x - 2)} - \frac{1}{3(x - 1)}$$

Hence

$$\int \frac{dx}{x^3 - x^2 - 4x + 4} = \int \frac{dx}{12(x + 2)} + \int \frac{dx}{4(x - 2)} - \int \frac{dx}{3(x - 1)}$$

**Parts** An extremely useful formula for integration is the relation

$$d(uv) = u \, dv + v \, du$$

and  $uv = \int u \, dv + \int v \, du$

or  $\int u \, dv = uv - \int v \, du$

### 3-24 MATHEMATICS

No general rule for breaking an integrand can be given. Experience alone limits the use of this technique. It is particularly useful for trigonometric and exponential functions.

**Example** Find  $\int xe^x dx$ . Let

$$\begin{aligned} u &= x & \text{and} & & dv &= e^x dx \\ du &= dx & & & v &= e^x \end{aligned}$$

Therefore 
$$\begin{aligned} \int xe^x dx &= xe^x - \int e^x dx \\ &= xe^x - e^x + c \end{aligned}$$

**Example** Find  $\int e^x \sin x dx$ . Let

$$\begin{aligned} u &= e^x & dv &= \sin x dx \\ du &= e^x dx & v &= -\cos x \end{aligned}$$

$$\int e^x \sin x dx = -e^x \cos x + \int e^x \cos x dx$$

Again 
$$\begin{aligned} u &= e^x & dv &= \cos x dx \\ du &= e^x dx & v &= \sin x \end{aligned}$$

$$\begin{aligned} \int e^x \sin x dx &= -e^x \cos x + e^x \sin x - \int e^x \sin x dx + c \\ &= (e^x/2)(\sin x - \cos x) + \frac{c}{2} \end{aligned}$$

**Series Expansion** When an explicit function cannot be found, the integration can sometimes be carried out by a series expansion.

**Example** Find  $\int e^{-x^2} dx$ . Since

$$e^{-x^2} = 1 - x^2 + \frac{x^4}{2!} - \frac{x^6}{3!} + \dots$$

$$\begin{aligned} \int e^{-x^2} dx &= \int dx - \int x^2 dx + \int \frac{x^4}{2!} dx - \int \frac{x^6}{3!} dx + \dots \\ &= x - \frac{x^3}{3} + \frac{x^5}{5 \cdot 2!} - \frac{x^7}{7 \cdot 3!} + \dots \quad \text{for all } x \end{aligned}$$

**Definite Integral** The concept and derivation of the definite integral are completely different from those for the indefinite integral. These are by definition different types of operations. However, the formal operation  $\int$  as it turns out treats the integrand in the same way for both.

Consider the function  $f(x) = 10 - 10e^{-2x}$ . Define  $x_1 = a$  and  $x_n = b$ , and suppose it is desirable to compute the area between the curve and the coordinate axis  $y = 0$  and bounded by  $x_1 = a$ ,  $x_n = b$ . Obviously, by a sufficiently large number of rectangles this area could be approximated as closely as desired by the formula

$$\begin{aligned} \sum_{i=1}^{n-1} f(\xi_i)(x_{i+1} - x_i) &= f(\xi_1)(x_2 - a) + f(\xi_2)(x_3 - x_2) \\ &+ \dots + f(\xi_{n-1})(b - x_{n-1}) \quad x_{i-1} \leq \xi_i \leq x_i \end{aligned}$$

The definite integral of  $f(x)$  is defined as

$$\int_a^b f(x) dx = \lim_{n \rightarrow \infty} \sum_{i=1}^n f(\xi_i)(x_{i+1} - x_i)$$

where the points  $x_1, x_2, \dots, x_n$  are equally spaced.

Thus, the value of a definite integral depends on the limits  $a, b$ , and any selected variable coefficients in the function but not on the dummy variable of integration  $x$ . Symbolically

$$F(x) = \int f(x) dx \quad \text{indefinite integral where } dF/dx = f(x)$$

or 
$$F(a, b) = \int_a^b f(x) dx \quad \text{definite integral}$$

$$F(\alpha) = \int_a^b f(x, \alpha) dx$$

There are certain restrictions of the integration definition. "The function  $f(x)$  must be continuous in the finite interval  $(a, b)$  with at most a finite number of finite discontinuities," which must be observed before integration formulas can be generally applied. Relaxing two of

these restrictions gives rise to so-called **improper integrals** and requires special handling. These occur when

1. The limits of integration are not both finite, i.e.,  $\int_0^\infty e^{-x} dx$ .
2. The function becomes infinite within the interval of integration, i.e.,

$$\int_0^1 \frac{1}{\sqrt{x}} dx$$

Techniques for determining when integration is valid under these conditions are available in the references.

**Properties** The fundamental theorem of calculus states

$$\int_a^b f(x) dx = F(b) - F(a)$$

where 
$$dF(x)/dx = f(x)$$

Other properties of the definite integral are

$$\int_a^b c[f(x) dx] = c \int_a^b f(x) dx$$

$$\int_a^b [f_1(x) + f_2(x)] dx = \int_a^b f_1(x) dx + \int_a^b f_2(x) dx$$

$$\int_a^b f(x) dx = -\int_b^a f(x) dx$$

$$\int_a^b f(x) dx = \int_a^c f(x) dx + \int_c^b f(x) dx$$

$$\int_a^b f(x) dx = (b - a)f(\xi) \quad \text{for some } \xi \text{ in } (a, b)$$

$$\frac{\partial}{\partial b} \int_a^b f(x) dx = f(b)$$

$$\frac{\partial}{\partial a} \int_a^b f(x) dx = -f(a)$$

$$\frac{dF(\alpha)}{d\alpha} = \int_a^b \frac{\partial f(x, \alpha)}{\partial \alpha} dx \quad \text{if } a \text{ and } b \text{ are constant}$$

$$\int_a^b dx \int_c^d f(x, \alpha) d\alpha = \int_c^d d\alpha \int_a^b f(x, \alpha) dx \quad (3-66)$$

When  $F(x) = \int_{a(x)}^{b(x)} f(x, y) dy$ , the Leibniz rule gives

$$\frac{dF}{dx} = \frac{db}{dx} f[x, b(x)] - \frac{da}{dx} f[x, a(x)] + \int_{a(x)}^{b(x)} \frac{\partial f}{\partial x} dy$$

**Example** Find  $\int_0^2 \frac{dx}{(x-1)^2}$ . Direct application of the formula would yield the incorrect value

$$\int_0^2 \frac{dx}{(x-1)^2} = \left[ -\frac{1}{x-1} \right]_0^2 = -2$$

It should be noted that  $f(x) = 1/(x-1)^2$  becomes unbounded as  $x \rightarrow 1$  and by Rule 2 the integral diverges and hence is said not to exist.

**Methods of Integration** All the methods of integration available for the indefinite integral can be used for definite integrals. In addition, several others are available for the latter integrals and are indicated below.

**Change of Variable** This substitution is basically the same as previously indicated for indefinite integrals. However, for definite integrals, the limits of integration must also be changed: i.e., for  $x = \phi(t)$ ,

$$\int_a^b f(x) dx = \int_{t_0}^{t_1} f[\phi(t)]\phi'(t) dt$$

where 
$$\begin{aligned} t &= t_0 \text{ when } x = a \\ t &= t_1 \text{ when } x = b \end{aligned}$$

**Example** Find  $\int_0^4 \sqrt{16-x^2} dx$ . Let  
 $x = 4 \sin \theta$  ( $x = 0, \theta = 0$ )  
 $dx = 4 \cos \theta d\theta$  ( $x = 4, \theta = \pi/2$ )

Then  $\int_0^4 \sqrt{16-x^2} dx = 16 \int_0^{\pi/2} \cos^2 \theta d\theta = 16[\frac{1}{2}\theta + \frac{1}{4} \sin 2\theta]_0^{\pi/2} = 4\pi$

**Integration** It is sometimes useful to generate a double integral to solve a problem. By this approach, the fundamental theorem indicated by Eq. (3-66) can be used.

**Example** Find  $\int_0^1 \frac{x^b - x^a}{\ln x} dx$

Consider  $\int_0^1 x^\alpha dx = \frac{1}{\alpha+1} (\alpha > -1)$

Then multiplying both sides by  $d\alpha$  and integrating between  $a$  and  $b$ ,

$$\int_a^b d\alpha \int_0^1 x^\alpha dx = \int_a^b \frac{d\alpha}{\alpha+1} = \ln \left| \frac{b+1}{a+1} \right|$$

But also

$$\int_a^b d\alpha \int_0^1 x^\alpha dx = \int_0^1 dx \int_a^b x^\alpha d\alpha = \int_0^1 \frac{x^b - x^a}{\ln x} dx$$

Therefore  $\int_0^1 \frac{x^b - x^a}{\ln x} dx = \ln \left| \frac{b+1}{a+1} \right|$

### INFINITE SERIES

**REFERENCES:** de Bruijn, N. G., *Asymptotic Methods in Analysis*, Dover, New York (1981); Folland, G. B., *Advanced Calculus*, Prentice-Hall, Saddle River, N.J. (2002); Gradshteyn, I. S., and I. M. Ryzhik, *Tables of Integrals, Series, and Products*, Academic, New York (2000); Kaplan, W., *Advanced Calculus*, 5th ed., Addison-Wesley, Redwood City, Calif. (2003).

#### DEFINITIONS

A succession of numbers or terms that are formed according to some definite rule is called a sequence. The indicated sum of the terms of a sequence is called a series. A series of the form  $a_0 + a_1(x-c) + a_2(x-c)^2 + \dots + a_n(x-c)^n + \dots$  is called a power series.

Consider the sum of a finite number of terms in the geometric series (a special case of a power series).

$$S_n = a + ar + ar^2 + ar^3 + \dots + ar^{n-1} \quad (3-67)$$

For any number of terms  $n$ , the sum equals

$$S_n = a \frac{1-r^n}{1-r}$$

In this form, the geometric series is assumed finite.

In the form of Eq. (3-67), it can further be defined that the terms in the series be nonending and therefore an infinite series.

$$S = a + ar + ar^2 + \dots + ar^n + \dots \quad (3-68)$$

However, the defined sum of the terms [Eq. (3-67)]

$$S_n = a \frac{1-r^n}{1-r} \quad r \neq 1$$

while valid for any finite value of  $r$  and  $n$  now takes on a different interpretation. In this sense it is necessary to consider the limit of  $S_n$  as  $n$  increases indefinitely:

$$\begin{aligned} S &= \lim_{n \rightarrow \infty} S_n \\ &= a \lim_{n \rightarrow \infty} \frac{1-r^n}{1-r} \end{aligned}$$

For this, it is stated the infinite series converges if the limit of  $S_n$  approaches a fixed finite value as  $n$  approaches infinity. Otherwise, the series is **divergent**.

On this basis an analysis of

$$S = a \lim_{n \rightarrow \infty} \frac{1-r^n}{1-r}$$

shows that if  $r$  is less than 1 but greater than  $-1$ , the infinite series is convergent. For values outside of the range  $-1 < r < 1$ , the series is divergent because the sum is not defined. The range  $-1 < r < 1$  is called the **region of convergence**. (We assume  $a \neq 0$ .)

There are also two types of convergent series. Consider the new series

$$S = 1 - \frac{1}{2} + \frac{1}{3} - \frac{1}{4} + \dots + (-1)^{n+1} \frac{1}{n} + \dots \quad (3-69)$$

It can be shown that the series (3-69) does converge to the value  $S = \log 2$ . However, if each term is replaced by its absolute value, the series becomes unbounded and therefore divergent (unbounded divergent):

$$S = 1 + \frac{1}{2} + \frac{1}{3} + \frac{1}{4} + \frac{1}{5} + \dots \quad (3-70)$$

In this case the series (3-69) is defined as a conditionally convergent series. If the replacement series of absolute values also converges, the series is defined to converge absolutely.

Series (3-69) is further defined as an alternating series, while series (3-70) is referred to as a positive series.

#### OPERATIONS WITH INFINITE SERIES

1. The convergence or divergence of an infinite series is unaffected by the removal of a finite number of finite terms. This is a trivial theorem but useful to remember, especially when using the comparison test to be described in the subsection "Tests for Convergence and Divergence."

2. If a series is conditionally convergent, its sums can be made to have any arbitrary value by a suitable rearrangement of the series; it can in fact be made divergent or oscillatory (Riemann's theorem).

3. A series of positive terms; if convergent, has a sum independent of the order of its terms; but if divergent, it remains divergent however its terms are rearranged.

4. An oscillatory series can always be made to converge by grouping terms.

5. A power series can be inverted, provided the first-degree term is not zero. Given

$$y = b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6 + b_7x^7 + \dots$$

then  $x = B_1y + B_2y^2 + B_3y^3 + B_4y^4 + B_5y^5 + B_6y^6 + B_7y^7 + \dots$

where  $B_1 = 1/b_1$

$$B_2 = -b_2/b_1^3$$

$$B_3 = (1/b_1^5)(2b_2^2 - b_1b_3)$$

$$B_4 = (1/b_1^7)(5b_1b_2b_3 - b_1^2b_4 - 5b_2^3)$$

Additional coefficients are available in the references.

6. Two series may be added or subtracted term by term provided each is a convergent series. The joint sum is equal to the sum (or difference) of the individuals.

7. The sum of two divergent series can be convergent. Similarly, the sum of a convergent series and a divergent series must be divergent.

8. A power series may be integrated term by term to represent the integral of the function within an interval of the region of convergence. If  $f(x) = a_0 + a_1x + a_2x^2 + \dots$ , then

$$\int_{x_1}^{x_2} f(x) dx = \int_{x_1}^{x_2} a_0 dx + \int_{x_1}^{x_2} a_1x dx + \int_{x_1}^{x_2} a_2x^2 dx + \dots$$

9. A power series may be differentiated term by term and represents the function  $df(x)/dx$  within the same region of convergence as  $f(x)$ .

**TESTS FOR CONVERGENCE AND DIVERGENCE**

In general, the problem of determining whether a given series will converge or not can require a great deal of ingenuity and resourcefulness. There is no all-inclusive test which can be applied to all series. As the only alternative, it is necessary to apply one or more of the developed theorems in an attempt to ascertain the convergence or divergence of the series under study. The following defined tests are given in relative order of effectiveness. For examples, see references on advanced calculus.

1. *Comparison Test.* A series will converge if the absolute value of each term (with or without a finite number of terms) is less than the corresponding term of a known convergent series. Similarly, a positive series is divergent if it is termwise larger than a known divergent series of positive terms.

2. *nth-Term Test.* A series is divergent if the  $n$ th term of the series does not approach zero as  $n$  becomes increasingly large.

3. *Ratio Test.* If the absolute ratio of the  $(n + 1)$  term divided by the  $n$ th term as  $n$  becomes unbounded approaches

- a. A number less than 1, the series is absolutely convergent
- b. A number greater than 1, the series is divergent
- c. A number equal to 1, the test is inconclusive

4. *Alternating-Series Leibniz Test.* If the terms of a series are alternately positive and negative and never increase in value, the absolute series will converge, provided that the terms tend to zero as a limit.

5. *Cauchy's Root Test.* If the  $n$ th root of the absolute value of the  $n$ th term, as  $n$  becomes unbounded, approaches

- a. A number less than 1, the series is absolutely convergent
- b. A number greater than 1, the series is divergent
- c. A number equal to 1, the test is inconclusive

6. *Maclaurin's Integral Test.* Suppose  $\sum a_n$  is a series of positive terms and  $f$  is a continuous decreasing function such that  $f(x) \geq 0$  for  $1 \leq x < \infty$  and  $f(n) = a_n$ . Then the series and the improper integral  $\int_1^\infty f(x) dx$  either both converge or both diverge.

**SERIES SUMMATION AND IDENTITIES**

**Sums for the First  $n$  Numbers to Integer Powers**

$$\sum_{j=1}^n j = \frac{n(n+1)}{2} = 1 + 2 + 3 + 4 + \dots + n$$

$$\sum_{j=1}^n j^2 = \frac{n(n+1)(2n+1)}{6} = 1^2 + 2^2 + 3^2 + 4^2 + \dots + n^2$$

$$\sum_{j=1}^n j^3 = \frac{n^2(n+1)^2}{4} = 1^3 + 2^3 + 3^3 + \dots + n^3$$

**Arithmetic Progression**

$$\begin{aligned} \sum_{k=1}^n [a + (k-1)d] &= a + (a+d) + (a+2d) \\ &\quad + (a+3d) + \dots + [a + (n-1)d] \\ &= na + \frac{1}{2}n(n-1)d \end{aligned}$$

**Geometric Progression**

$$\sum_{j=1}^n ar^{j-1} = a + ar + ar^2 + ar^3 + \dots + ar^{n-1} = a \frac{1-r^n}{1-r} \quad r \neq 1$$

**Harmonic Progression**

$$\sum_{k=0}^n \frac{1}{a+kd} = \frac{1}{a} + \frac{1}{a+d} + \frac{1}{a+2d} + \frac{1}{a+3d} + \frac{1}{a+4d} + \dots + \frac{1}{a+nd}$$

The reciprocals of the terms of the arithmetic-progression series are called harmonic progression. No general summation formulas are available for this series.

**Binomial Series (see also Elementary Algebra)**

$$(1 \pm x)^n = 1 \pm nx + \frac{n(n-1)}{2!}x^2 \pm \frac{n(n-1)(n-2)}{3!}x^3 + \dots \quad (x^2 < 1)$$

**Taylor's Series**

$$f(h+x) = f(h) + xf'(h) + \frac{x^2}{2!}f''(h) + \frac{x^3}{3!}f'''(h) + \dots$$

$$\text{or } f(x) = f(x_0) + f'(x_0)(x-x_0) + \frac{f''(x_0)}{2!}(x-x_0)^2 + \frac{f'''(x_0)}{3!}(x-x_0)^3 + \dots$$

*Example* Find a series expansion for  $f(x) = \ln(1+x)$  about  $x_0 = 0$ .

$$f(x) = (1+x)^{-1}, \quad f'(x) = -(1+x)^{-2}, \quad f''(x) = 2(1+x)^{-3}, \text{ etc.}$$

thus  $f(0) = 0, \quad f'(0) = 1, \quad f''(0) = -1, \quad f'''(0) = 2, \text{ etc.}$

$$\ln(1+x) = x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \dots + (-1)^{n+1} \frac{x^n}{n} + \dots$$

which converges for  $-1 < x \leq 1$ .

**Maclaurin's Series**

$$f(x) = f(0) + xf'(0) + \frac{x^2}{2!}f''(0) + \frac{x^3}{3!}f'''(0) + \dots$$

This is simply a special case of Taylor's series when  $h$  is set to zero.

**Exponential Series**

$$e^x = 1 + x + \frac{x^2}{2!} + \frac{x^3}{3!} + \dots + \frac{x^n}{n!} + \dots \quad -\infty < x < \infty$$

**Logarithmic Series**

$$\ln x = \frac{x-1}{x} + \frac{1}{2} \left( \frac{x-1}{x} \right)^2 + \frac{1}{3} \left( \frac{x-1}{x} \right)^3 + \dots \quad (x > 1/2)$$

$$\ln x = 2 \left[ \frac{x-1}{x+1} \right] + \frac{1}{3} \left( \frac{x-1}{x+1} \right)^3 + \dots \quad (x > 0)$$

**Trigonometric Series\***

$$\sin x = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \dots \quad -\infty < x < \infty$$

$$\cos x = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \dots \quad -\infty < x < \infty$$

$$\sin^{-1} x = x + \frac{x^3}{6} + \frac{1}{2} \cdot \frac{3}{4} \cdot \frac{x^5}{5} + \frac{1}{2} \cdot \frac{3}{4} \cdot \frac{5}{6} \cdot \frac{x^7}{7} + \dots \quad (x^2 < 1)$$

$$\tan^{-1} x = x - \frac{1}{3}x^3 + \frac{1}{5}x^5 - \frac{1}{7}x^7 + \dots \quad (x^2 < 1)$$

**Taylor Series** The Taylor series for a function of two variables, expanded about the point  $(x_0, y_0)$ , is

\*  $\tan x$  series has awkward coefficients and should be computed as  $\left[ (\text{sign}) \frac{\sin x}{\sqrt{1-\sin^2 x}} \right]$ .

$$f(x, y) = f(x_0, y_0) + \left. \frac{\partial f}{\partial x} \right|_{x_0, y_0} (x - x_0) + \left. \frac{\partial f}{\partial y} \right|_{x_0, y_0} (y - y_0) + \frac{1}{2!} \left[ \left. \frac{\partial^2 f}{\partial x^2} \right|_{x_0, y_0} (x - x_0)^2 + 2 \left. \frac{\partial^2 f}{\partial x \partial y} \right|_{x_0, y_0} (x - x_0)(y - y_0) + \left. \frac{\partial^2 f}{\partial y^2} \right|_{x_0, y_0} (y - y_0)^2 \right] + \dots$$

**Partial Sums of Infinite Series, and How They Grow** Calculus textbooks devote much space to tests for convergence and divergence of series that are of little practical value, since a convergent series either converges rapidly, in which case almost any test (among those presented in the preceding subsections) will do; or it converges slowly, in which case it is not going to be of much use unless there is some way to get at its sum without adding up an unreasonable number of terms. To find out, as accurately as possible, how fast a convergent series converges and how fast a divergent series diverges, see Boas, R. P., Jr., *Am. Math. Mon.* **84**: 237–258 (1977).

## COMPLEX VARIABLES

**REFERENCES:** Ablowitz, M. J., and A. S. Fokas, *Complex Variables: Introduction and Applications*, Cambridge University Press, New York (2003); Asmar, N., and G. C. Churchill, *Complex Variables and Applications*, 7th ed., McGraw-Hill, New York (2003); Kaplan, W., *Advanced Calculus*, 5th ed., Addison-Wesley, Redwood City, Calif. (2003); Kwok, Y. K., *Applied Complex Variables for Scientists and Engineers*, Cambridge University Press, New York (2002); McGehee, O. C., *An Introduction to Complex Analysis*, Wiley, New York (2000); Priestley, H. A., *Introduction to Complex Analysis*, Oxford University Press, New York (2003).

Numbers of the form  $z = x + iy$ , where  $x$  and  $y$  are real,  $i^2 = -1$ , are called complex numbers. The numbers  $z = x + iy$  are representable in the plane as shown in Fig. 3-45. The following definitions and terminology are used:

1. Distance  $OP = r$  = modulus of  $z$  written  $|z|$ .  $|z| = \sqrt{x^2 + y^2}$ .
2.  $x$  is the real part of  $z$ .
3.  $y$  is the imaginary part of  $z$ .
4. The angle  $\theta$ ,  $0 \leq \theta < 2\pi$ , measured counterclockwise from the positive  $x$  axis to  $OP$  is the argument of  $z$ .  $\theta = \arctan y/x = \arcsin y/r = \arccos x/r$  if  $x \neq 0$ ,  $\theta = \pi/2$  if  $x = 0$  and  $y > 0$ .
5. The numbers  $r, \theta$  are the polar coordinates of  $z$ .
6.  $\bar{z} = x - iy$  is the complex conjugate of  $z$ .

### ALGEBRA

Let  $z_1 = x_1 + iy_1, z_2 = x_2 + iy_2$ .

**Equality**  $z_1 = z_2$  if and only if  $x_1 = x_2$  and  $y_1 = y_2$ .

**Addition**  $z_1 + z_2 = (x_1 + x_2) + i(y_1 + y_2)$ .

**Subtraction**  $z_1 - z_2 = (x_1 - x_2) + i(y_1 - y_2)$ .

**Multiplication**  $z_1 \cdot z_2 = (x_1x_2 - y_1y_2) + i(x_1y_2 + x_2y_1)$ .

**Division**  $z_1/z_2 = \frac{x_1x_2 + y_1y_2}{x_2^2 + y_2^2} + i \frac{x_2y_1 - x_1y_2}{x_2^2 + y_2^2}, z_2 \neq 0$ .

### SPECIAL OPERATIONS

$\bar{z}\bar{z} = x^2 + y^2 = |z|^2; \overline{z_1 \pm z_2} = \bar{z}_1 \pm \bar{z}_2; \overline{\bar{z}_1} = z_1; \overline{z_1 z_2} = \bar{z}_1 \bar{z}_2; |z_1 \cdot z_2| = |z_1| \cdot |z_2|; \arg(z_1 \cdot z_2) = \arg z_1 + \arg z_2; \arg(\bar{z}_1/z_2) = \arg z_1 - \arg z_2; i^{4n} = 1$  for  $n$  any integer;  $i^{2n} = -1$  where  $n$  is any odd integer;  $z + \bar{z} = 2x; z - \bar{z} = 2iy$ .

Every complex quantity can be expressed in the form  $x + iy$ .

### TRIGONOMETRIC REPRESENTATION

By referring to Fig. 3-45, there results  $x = r \cos \theta, y = r \sin \theta$  so that  $z = x + iy = r(\cos \theta + i \sin \theta)$ , which is called the polar form of the

FIG. 3-45 Complex plane.

complex number.  $\cos \theta + i \sin \theta = e^{i\theta}$ . Hence  $z = x + iy = re^{i\theta}, \bar{z} = x - iy = re^{-i\theta}$ . Two important results from this are  $\cos \theta = (e^{i\theta} + e^{-i\theta})/2$  and  $\sin \theta = (e^{i\theta} - e^{-i\theta})/2i$ . Let  $z_1 = r_1 e^{i\theta_1}, z_2 = r_2 e^{i\theta_2}$ . This form is convenient for multiplication for  $z_1 z_2 = r_1 r_2 e^{i(\theta_1 + \theta_2)}$  and for division for  $z_1/z_2 = (r_1/r_2)e^{i(\theta_1 - \theta_2)}, z_2 \neq 0$ .

### POWERS AND ROOTS

If  $n$  is a positive integer,  $z^n = (re^{i\theta})^n = r^n e^{in\theta} = r^n(\cos n\theta + i \sin n\theta)$ .

If  $n$  is a positive integer,

$$z^{1/n} = r^{1/n} e^{i[(\theta + 2k\pi)/n]} = r^{1/n} \left[ \cos \left( \frac{\theta + 2k\pi}{n} \right) + i \sin \left( \frac{\theta + 2k\pi}{n} \right) \right]$$

and selecting values of  $k = 0, 1, 2, 3, \dots, n - 1$  give the  $n$  distinct values of  $z^{1/n}$ . The  $n$  roots of a complex quantity are uniformly spaced around a circle, with radius  $r^{1/n}$ , in the complex plane in a symmetric fashion.

**Example** Find the three cube roots of  $-8$ . Here  $r = 8, \theta = \pi$ . The roots are  $z_0 = 2(\cos \pi/3 + i \sin \pi/3) = 1 + i\sqrt{3}, z_1 = 2(\cos \pi + i \sin \pi) = -2, z_2 = 2(\cos 5\pi/3 + i \sin 5\pi/3) = 1 - i\sqrt{3}$ .

### ELEMENTARY COMPLEX FUNCTIONS

**Polynomials** A polynomial in  $z, a_n z^n + a_{n-1} z^{n-1} + \dots + a_0$ , where  $n$  is a positive integer, is simply a sum of complex numbers times integral powers of  $z$  which have already been defined. Every polynomial of degree  $n$  has precisely  $n$  complex roots provided each multiple root of multiplicity  $m$  is counted  $m$  times.

**Exponential Functions** The exponential function  $e^z$  is defined by the equation  $e^z = e^{x+iy} = e^x \cdot e^{iy} = e^x(\cos y + i \sin y)$ . Properties:  $e^0 = 1; e^{z_1} \cdot e^{z_2} = e^{z_1+z_2}; e^{z_1}/e^{z_2} = e^{z_1-z_2}; e^{z+2k\pi i} = e^z$ .

**Trigonometric Functions**  $\sin z = (e^{iz} - e^{-iz})/2i; \cos z = (e^{iz} + e^{-iz})/2; \tan z = \sin z/\cos z; \cot z = \cos z/\sin z; \sec z = 1/\cos z; \csc z = 1/\sin z$ . Fundamental identities for these functions are the same as their real counterparts. Thus  $\cos^2 z + \sin^2 z = 1, \cos(z_1 \pm z_2) = \cos z_1 \cos z_2 \mp \sin z_1 \sin z_2, \sin(z_1 \pm z_2) = \sin z_1 \cos z_2 \pm \cos z_1 \sin z_2$ . The sine and cosine of  $z$  are periodic functions of period  $2\pi$ ; thus  $\sin(z + 2\pi) = \sin z$ . For computation purposes  $\sin z = \sin(x + iy) = \sin x \cosh y + i \cos x \sinh y$ , where  $\sin x, \cosh y$ , etc., are the real trigonometric and hyperbolic functions. Similarly,  $\cos z = \cos x \cosh y - i \sin x \sinh y$ . If  $x = 0$  in the results given,  $\cos iy = \cosh y, \sin iy = i \sinh y$ .

**Example** Find all solutions of  $\sin z = 3$ . From previous data  $\sin z = \sin x \cosh y + i \cos x \sinh y = 3$ . Equating real and imaginary parts  $\sin x \cosh y = 3, \cos x \sinh y = 0$ . The second equation can hold for  $y = 0$  or for  $x = \pi/2, 3\pi/2, \dots$ . If  $y = 0, \cosh 0 = 1$  and  $\sin x = 3$  is impossible for real  $x$ . Therefore,  $x = \pm \pi/2, \pm 3\pi/2, \dots, \pm(2n + 1)\pi/2, n = 0, \pm 1, \pm 2, \dots$ . However,  $\sin 3\pi/2 = -1$  and  $\cosh y \geq 1$ . Hence  $x = \pi/2, 5\pi/2, \dots$ . The solution is  $z = [(4n + 1)\pi]/2 + i \cosh^{-1} 3, n = 0, 1, 2, 3, \dots$ .

**Example** Find all solutions of  $e^z = -i$ .  $e^z = e^x(\cos y + i \sin y) = -i$ . Equating real and imaginary parts gives  $e^x \cos y = 0, e^x \sin y = -1$ . From the first  $y = \pm \pi/2, \pm 3\pi/2, \dots$ . But  $e^x > 0$ . Therefore,  $y = 3\pi/2, 7\pi/2, -\pi/2, \dots$ . Then  $x = 0$ . The solution is  $z = i[(4n + 3)\pi]/2$ .

Two important facets of these functions should be recognized. First, the  $\sin z$  is *unbounded*; and, second,  $e^z$  takes *all* complex values *except* 0.

**Hyperbolic Functions**  $\sinh z = (e^z - e^{-z})/2$ ;  $\cosh z = (e^z + e^{-z})/2$ ;  $\tanh z = \sinh z/\cosh z$ ;  $\coth z = \cosh z/\sinh z$ ;  $\operatorname{csch} z = 1/\sinh z$ ;  $\operatorname{sech} z = 1/\cosh z$ . Identities are:  $\cosh^2 z - \sinh^2 z = 1$ ;  $\sinh(z_1 + z_2) = \sinh z_1 \cosh z_2 + \cosh z_1 \sinh z_2$ ;  $\cosh(z_1 + z_2) = \cosh z_1 \cosh z_2 + \sinh z_1 \sinh z_2$ ;  $\cosh z + \sinh z = e^z$ ;  $\cosh z - \sinh z = e^{-z}$ . The hyperbolic sine and hyperbolic cosine are periodic functions with the imaginary period  $2\pi i$ . That is,  $\sinh(z + 2\pi i) = \sinh z$ .

**Logarithms** The logarithm of  $z$ ,  $\log z = \log |z| + i(\theta + 2n\pi)$ , where  $\log |z|$  is taken to the base  $e$  and  $\theta$  is the principal argument of  $z$ , that is, the particular argument lying in the interval  $0 \leq \theta < 2\pi$ . The logarithm of  $z$  is infinitely many valued. If  $n = 0$ , the resulting logarithm is called the principal value. The familiar laws  $\log z_1 z_2 = \log z_1 + \log z_2$ ,  $\log z_1/z_2 = \log z_1 - \log z_2$ ,  $\log z^n = n \log z$  hold for the principal value.

General powers of  $z$  are defined by  $z^\alpha = e^{\alpha \log z}$ . Since  $\log z$  is infinitely many valued, so too is  $z^\alpha$  unless  $\alpha$  is a rational number.

DeMoivre's formula can be derived from properties of  $e^z$ .

$$z^n = r^n (\cos \theta + i \sin \theta)^n = r^n (\cos n\theta + i \sin n\theta)$$

Thus  $(\cos \theta + i \sin \theta)^n = \cos n\theta + i \sin n\theta$

**COMPLEX FUNCTIONS (ANALYTIC)**

In the real-number system  $a$  greater than  $b(a > b)$  and  $b$  less than  $c(b < c)$  define an order relation. These relations have no meaning for complex numbers. The absolute value is used for ordering. Some important relations follow:  $|z| \geq x$ ;  $|z| \geq y$ ;  $|z_1 \pm z_2| \leq |z_1| + |z_2|$ ;  $|z_1 - z_2| \geq ||z_1| - |z_2||$ ;  $|z| \geq (|x| + |y|)/\sqrt{2}$ . Parts of the complex plane, commonly called **regions** or **domains**, are described by using inequalities.

**Example**  $|z - 3| \leq 5$ . This is equivalent to  $\sqrt{(x - 3)^2 + y^2} \leq 5$ , which is the set of all points within and on the circle, centered at  $x = 3, y = 0$  of radius 5.

**Example**  $|z - 1| \leq x$  represents the set of all points inside and on the parabola  $2x = y^2 + 1$  or, equivalently,  $2x \geq y^2 + 1$ .

**Functions of a Complex Variable** If  $z = x + iy, w = u + iv$  and if for each value of  $z$  in some region of the complex plane one or more values of  $w$  are defined, then  $w$  is said to be a function of  $z, w = f(z)$ . Some of these functions have already been discussed, e.g.,  $\sin z, \log z$ . All functions are reducible to the form  $w = u(x, y) + iv(x, y)$ , where  $u, v$  are real functions of the real variables  $x$  and  $y$ .

**Example**  $z^3 = (x + iy)^3 = x^3 + 3x^2(iy) + 3x(iy)^2 + (iy)^3 = (x^3 - 3xy^2) + i(3x^2y - y^3)$ .

**Differentiation** The derivative of  $w = f(z)$  is

$$\frac{dw}{dz} = \lim_{\Delta z \rightarrow 0} \frac{f(z + \Delta z) - f(z)}{\Delta z}$$

and for the derivative to exist the limit must be the same no matter how  $\Delta z$  approaches zero. If  $w_1, w_2$  are differentiable functions of  $z$ , the following rules apply:

$$\frac{d(w_1 \pm w_2)}{dz} = \frac{dw_1}{dz} \pm \frac{dw_2}{dz} \quad \frac{d(w_1 w_2)}{dz} = w_2 \frac{dw_1}{dz} + w_1 \frac{dw_2}{dz}$$

$$\frac{d(w_1/w_2)}{dz} = \frac{w_2(dw_1/dz) - w_1(dw_2/dz)}{w_2^2}$$

and  $\frac{dw_1^n}{dz} = n w_1^{n-1} \frac{dw_1}{dz}$

For  $w = f(z)$  to be differentiable, it is necessary that  $\partial u/\partial x = \partial v/\partial y$  and  $\partial v/\partial x = -\partial u/\partial y$ . The last two equations are called the Cauchy-Riemann equations. The derivative

$$\frac{dw}{dz} = \frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x} = \frac{\partial v}{\partial y} - i \frac{\partial u}{\partial y}$$

If  $f(z)$  possesses a derivative at  $z_0$  and at every point in some neighborhood of  $z_0$ , then  $f(z)$  is said to be analytic or homomorphic at  $z_0$ . If the

Cauchy-Riemann equations are satisfied and

$$u, v, \frac{\partial u}{\partial x}, \frac{\partial u}{\partial y}, \frac{\partial v}{\partial x}, \frac{\partial v}{\partial y}$$

are continuous in a region of the complex plane, then  $f(z)$  is analytic in that region.

**Example**  $w = z\bar{z} = x^2 + y^2$ . Here  $u = x^2 + y^2, v = 0, \partial u/\partial x = 2x, \partial u/\partial y = 2y, \partial v/\partial x = \partial v/\partial y = 0$ . These are continuous everywhere, but the Cauchy-Riemann equations hold only at the origin. Therefore,  $w$  is nowhere analytic, but it is differentiable at  $z = 0$  only.

**Example**  $w = e^z = e^x \cos y + ie^x \sin y, u = e^x \cos y, v = e^x \sin y, \partial u/\partial x = e^x \cos y, \partial u/\partial y = -e^x \sin y, \partial v/\partial x = e^x \sin y, \partial v/\partial y = e^x \cos y$ . The continuity and Cauchy-Riemann requirements are satisfied for all finite  $z$ . Hence  $e^z$  is analytic (except at  $\infty$ ) and  $dw/dz = \partial u/\partial x + i(\partial v/\partial x) = e^z$ .

**Example**  $w = \frac{1}{z} = \frac{x - iy}{x^2 + y^2} = \frac{x}{x^2 + y^2} - i \frac{y}{x^2 + y^2}$

It is easy to see that  $dw/dz$  exists except at  $z = 0$ . Thus  $1/z$  is analytic except at  $z = 0$ .

**Singular Points** If  $f(z)$  is analytic in a region except at certain points, those points are called singular points.

**Example**  $1/z$  has a singular point at zero.

**Example**  $\tan z$  has singular points at  $z = \pm(2n + 1)(\pi/2), n = 0, 1, 2, \dots$

The derivatives of the common functions, given earlier, are the same as their real counterparts.

**Example**  $(d/dz)(\log z) = 1/z, (d/dz)(\sin z) = \cos z$ .

**Harmonic Functions** Both the *real* and the *imaginary* parts of any analytic function  $f = u + iv$  satisfy Laplace's equation  $\partial^2\phi/\partial x^2 + \partial^2\phi/\partial y^2 = 0$ . A function which possesses continuous second partial derivatives and satisfies Laplace's equation is called a harmonic function.

**Example**  $e^z = e^x \cos y + ie^x \sin y, u = e^x \cos y, \partial u/\partial x = e^x \cos y, \partial^2 u/\partial x^2 = e^x \cos y, \partial u/\partial y = -e^x \sin y, \partial^2 u/\partial y^2 = -e^x \cos y$ . Clearly  $\partial^2 u/\partial x^2 + \partial^2 u/\partial y^2 = 0$ . Similarly,  $v = e^x \sin y$  is also harmonic.

If  $w = u + iv$  is analytic, the curves  $u(x, y) = c$  and  $v(x, y) = k$  intersect at right angles, if  $w'(z) \neq 0$ .

**Integration** In much of the work with complex variables a simple extension of integration called line or curvilinear integration is of fundamental importance. Since any complex line integral can be expressed in terms of real line integrals, we define only real line integrals. Let  $F(x, y)$  be a real, continuous function of  $x$  and  $y$  and  $c$  be any continuous curve of finite length joining the points  $A$  and  $B$  (Fig. 3-46).  $F(x, y)$  is not related to the curve  $c$ . Divide  $c$  up into  $n$  segments,  $\Delta s_i$  whose projection on the  $x$  axis is  $\Delta x_i$  and on the  $y$  axis is  $\Delta y_i$ . Let  $(\epsilon_i, \eta_i)$  be the coordinates of an arbitrary point on  $\Delta s_i$ . The limits of the sums

$$\lim_{\Delta s_i \rightarrow 0} \sum_{i=1}^n F(\epsilon_i, \eta_i) \Delta s_i = \int_c F(x, y) ds$$

FIG. 3-46 Line integral.

$$\lim_{\Delta x_i \rightarrow 0} \sum_{i=1}^n F(\epsilon_i, \eta_i) \Delta x_i = \int_c F(x, y) dx$$

$$\lim_{\Delta y_i \rightarrow 0} \sum_{i=1}^n F(\epsilon_i, \eta_i) \Delta y_i = \int_c F(x, y) dy$$

are known as line integrals. Much of the initial strangeness of these integrals will vanish if it be observed that the ordinary definite integral  $\int_a^b f(x) dx$  is just a line integral in which the curve  $c$  is a line segment on the  $x$  axis and  $F(x, y)$  is a function of  $x$  alone. The evaluation of line integrals can be reduced to evaluation of ordinary integrals.

**Example**  $\int_c y(1+x) dy$ , where  $c: y = 1 - x^2$  from  $(-1, 0)$  to  $(1, 0)$ . Clearly  $y = 1 - x^2, dy = -2x dx$ . Thus  $\int_c y(1+x) dy = -2 \int_{-1}^1 (1-x^2)(1+x) dx = -\frac{9}{5}$ .

**Example**  $\int_c x^2 y ds$ ,  $c$  is the square whose vertices are  $(0, 0), (1, 0), (1, 1), (0, 1)$ .  $ds = \sqrt{dx^2 + dy^2}$ . When  $dx = 0, ds = dy$ . From  $(0, 0)$  to  $(1, 0), y = 0, dy = 0$ . Similar arguments for the other sides give

$$\int_c x^2 y ds = \int_0^1 0 \cdot x^2 dx + \int_0^1 y dy + \int_1^0 x^2 dx + \int_1^0 0 \cdot y dy = \frac{1}{2} - \frac{1}{2} = 0$$

Let  $f(z)$  be any function of  $z$ , analytic or not, and  $c$  any curve as above. The complex integral is calculated as  $\int_c f(z) dz = \int_c (u dx - v dy) + i \int_c (v dx + u dy)$ , where  $f(z) = u(x, y) + iv(x, y)$ . Properties of line integrals are the same as those for ordinary integrals. That is,  $\int_c [f(z) \pm g(z)] dz = \int_c f(z) dz \pm \int_c g(z) dz$ ;  $\int_c kf(z) dz = k \int_c f(z) dz$  for any constant  $k$ , etc.

**Example**  $\int_c (x^2 + iy) dz$  along  $c: y = x, 0$  to  $1 + i$ . This becomes

$$\int_c (x^2 + iy) dz = \int_c (x^2 dx - y dy) + i \int_c (y dx + x^2 dy) = \int_0^1 x^2 dx - \int_0^1 x dx + i \int_0^1 x dx + i \int_0^1 x^2 dx = -\frac{1}{6} + 5i/6$$

FIG. 3-47 Conformal transformation.

**Conformal Mapping** Every function of a complex variable  $w = f(z) = u(x, y) + iv(x, y)$  transforms the  $x, y$  plane into the  $u, v$  plane in some manner. A conformal transformation is one in which angles between curves are preserved in *magnitude* and *sense*. Every analytic function, except at those points where  $f'(z) = 0$ , is a conformal transformation. See Fig. 3-47.

**Example**  $w = z^2, u + iv = (x^2 - y^2) + 2ixy$  or  $u = x^2 - y^2, v = 2xy$ . These are the transformation equations between the  $(x, y)$  and  $(u, v)$  planes. Lines parallel to the  $x$  axis,  $y = c_1$  map into curves in the  $u, v$  plane with parametric equations  $u = x^2 - c_1^2, v = 2c_1x$ . Eliminating  $x, u = (v^2/4c_1^2) - c_1^2$ , which represents a family of parabolas with the origin of the  $v$  plane as focus, the line  $v = 0$  as axis and opening to the right. Similar arguments apply to  $x = c_2$ .

The principles of complex variables are useful in the solution of a variety of applied problems, including Laplace transforms and process control (Sec. 8).

## DIFFERENTIAL EQUATIONS

The natural laws in any scientific or technological field are not regarded as precise and definitive until they have been expressed in mathematical form. Such a form, often an equation, is a relation between the quantity of interest, say, product yield, and independent variables such as time and temperature upon which yield depends. When it happens that this equation involves, besides the function itself, one or more of its derivatives it is called a differential equation.

**Example** The rate of the homogeneous bimolecular reaction  $A + B \xrightarrow{k} C$  is characterized by the differential equation  $dx/dt = k(a-x)(b-x)$ , where  $a =$  initial

concentration of  $A, b =$  initial concentration of  $B$ , and  $x = x(t) =$  concentration of  $C$  as a function of time  $t$ .

**Example** The differential equation of heat conduction in a moving fluid with velocity components  $v_x, v_y$  is

$$\frac{\partial u}{\partial t} + v_x \frac{\partial u}{\partial x} + v_y \frac{\partial u}{\partial y} = \frac{K}{\rho c_p} \left( \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} \right)$$

where  $u = u(x, y, t) =$  temperature,  $K =$  thermal conductivity,  $\rho =$  density, and  $c_p =$  specific heat at constant pressure.

## ORDINARY DIFFERENTIAL EQUATIONS

When the function involved in the equation depends upon only one variable, its derivatives are ordinary derivatives and the differential equation is called an ordinary differential equation. When the function depends upon several independent variables, then the equation is called a partial differential equation. The theories of ordinary and partial differential equations are quite different. In almost every respect the latter is more difficult.

Whichever the type, a differential equation is said to be of  $n$ th order if it involves derivatives of order  $n$  but no higher. The equation in the first example is of first order and that in the second example of second order. The degree of a differential equation is the power to which the derivative of the highest order is raised after the equation has been cleared of fractions and radicals in the dependent variable and its derivatives.

A relation between the variables, involving no derivatives, is called a solution of the differential equation if this relation, when substituted in the equation, satisfies the equation. A solution of an ordinary differential equation which includes the maximum possible number of "arbitrary" constants is called the **general solution**. The maximum number of "arbitrary" constants is exactly equal to the order of the

### 3-30 MATHEMATICS

differential equation. If any set of specific values of the constants is chosen, the result is called a **particular solution**.

**Example** The general solution of  $(d^2x/dt^2) + k^2x = 0$  is  $x = A \cos kt + B \sin kt$ , where  $A, B$  are arbitrary constants. A particular solution is  $x = \frac{1}{2} \cos kt + 3 \sin kt$ .

In the case of some equations still other solutions exist called singular solutions. A **singular solution** is any solution of the differential equation which is not included in the general solution.

**Example**  $y = x(dy/dx) - \sqrt{A(dy/dx)^2}$  has the general solution  $y = cx - \frac{1}{4}c^2$ , where  $c$  is an arbitrary constant;  $y = x^2$  is a singular solution, as is easily verified.

## ORDINARY DIFFERENTIAL EQUATIONS OF THE FIRST ORDER

**Equations with Separable Variables** Every differential equation of the first order and of the first degree can be written in the form  $M(x, y) dx + N(x, y) dy = 0$ . If the equation can be transformed so that  $M$  does not involve  $y$  and  $N$  does not involve  $x$ , then the variables are said to be separated. The solution can then be obtained by **quadrature**, which means that  $y = \int f(x) dx + c$ , which may or may not be expressible in simpler form.

**Example** Two liquids  $A$  and  $B$  are boiling together in a vessel. Experimentally it is found that the ratio of the rates at which  $A$  and  $B$  are evaporating at any time is proportional to the ratio of the amount of  $A$  (say,  $x$ ) to the amount of  $B$  (say,  $y$ ) still in the liquid state. This physical law is expressible as  $(dy/dt)/(dx/dt) = ky/x$  or  $dy/dx = ky/x$ , where  $k$  is a proportionality constant. This equation may be written  $dy/y = k(dx/x)$ , in which the variables are separated. The solution is  $\ln y = k \ln x + \ln c$  or  $y = cx^k$ .

**Exact Equations** The equation  $M(x, y) dx + N(x, y) dy = 0$  is exact if and only if  $\partial M/\partial y = \partial N/\partial x$ . In this case there exists a function  $w = f(x, y)$  such that  $\partial f/\partial x = M$ ,  $\partial f/\partial y = N$ , and  $f(x, y) = C$  is the required solution.  $f(x, y)$  is found as follows: treat  $y$  as though it were constant and evaluate  $\int M(x, y) dx$ . Then treat  $x$  as though it were constant and evaluate  $\int N(x, y) dy$ . The sum of all unlike terms in these two integrals (including no repetitions) is  $f(x, y)$ .

**Example**  $(2xy - \cos x) dx + (x^2 - 1) dy = 0$  is exact for  $\partial M/\partial y = 2x$ ,  $\partial N/\partial x = 2x$ .  $\int M dx = \int (2xy - \cos x) dx = x^2y - \sin x$ ,  $\int N dy = \int (x^2 - 1) dy = x^2y - y$ . The solution is  $x^2y - \sin x - y = C$ , as may easily be verified.

**Linear Equations** A differential equation is said to be linear when it is of first degree in the dependent variable and its derivatives. The general linear first-order differential equation has the form  $dy/dx + P(x)y = Q(x)$ . Its general solution is

$$y = e^{-\int P dx} \left[ \int Q e^{\int P dx} dx + C \right]$$

**Example** A tank initially holds 200 gal of a salt solution in which 100 lb is dissolved. Six gallons of brine containing 4 lb of salt run into the tank per minute. If mixing is perfect and the output rate is 4 gal/min, what is the amount  $A$  of salt in the tank at time  $t$ ? The differential equation of  $A$  is  $dA/dt = [2/(100 + t)]A = 4$ . Its general solution is  $A = (4/3)(100 + t) + C/(100 + t)^2$ . At  $t = 0$ ,  $A = 100$ ; so the particular solution is  $A = (4/3)(100 + t) - (1/3)10^6/(100 + t)^2$ .

## ORDINARY DIFFERENTIAL EQUATIONS OF HIGHER ORDER

The higher-order differential equations, especially those of order 2, are of great importance because of physical situations describable by them.

**Equation  $y^{(n)} = f(x)$**  Such a differential equation can be solved by  $n$  integrations. The solution will contain  $n$  arbitrary constants.

**Linear Differential Equations with Constant Coefficients and Right-Hand Member Zero (Homogeneous)** The solution of  $y'' + ay' + by = 0$  depends upon the nature of the roots of the characteristic equation  $m^2 + am + b = 0$  obtained by substituting the trial solution  $y = e^{mx}$  in the equation.

**Distinct Real Roots** If the roots of the characteristic equation are distinct real roots,  $r_1$  and  $r_2$ , say, the solution is  $y = Ae^{r_1x} + Be^{r_2x}$ , where  $A$  and  $B$  are arbitrary constants.

**Example**  $y'' + 4y' + 3 = 0$ . The characteristic equation is  $m^2 + 4m + 3 = 0$ . The roots are  $-3$  and  $-1$ , and the general solution is  $y = Ae^{-3x} + Be^{-x}$ .

**Multiple Real Roots** If  $r_1 = r_2$ , the solution of the differential equation is  $y = e^{r_1x}(A + Bx)$ .

**Example**  $y'' + 4y' + 4 = 0$ . The characteristic equation is  $m^2 + 4m + 4 = 0$  with roots  $-2$  and  $-2$ . The solution is  $y = e^{-2x}(A + Bx)$ .

**Complex Roots** If the characteristic roots are  $p \pm iq$ , then the solution is  $y = e^{px}(A \cos qx + B \sin qx)$ .

**Example** The differential equation  $My'' + Ay' + ky = 0$  represents the vibration of a linear system of mass  $M$ , spring constant  $k$ , and damping constant  $A$ . If  $A < 2\sqrt{kM}$ , the roots of the characteristic equation

$$Mm^2 + Am + k = 0 \text{ are complex } -\frac{A}{2M} \pm i \sqrt{\frac{k}{M} - \left(\frac{A}{2M}\right)^2}$$

and the solution is

$$y = e^{-(A/2M)t}$$

$$\left\{ c_1 \cos \left( \sqrt{\frac{k}{M} - \left(\frac{A}{2M}\right)^2} t \right) + c_2 \sin \left( \sqrt{\frac{k}{M} - \left(\frac{A}{2M}\right)^2} t \right) \right\}$$

This solution is oscillatory, representing undercritical damping.

All these results generalize to homogeneous linear differential equations with constant coefficients of order higher than 2. These equations (especially of order 2) have been much used because of the ease of solution. Oscillations, electric circuits, diffusion processes, and heat-flow problems are a few examples for which such equations are useful.

**Second-Order Equations: Dependent Variable Missing** Such an equation is of the form

$$F \left( x, \frac{dy}{dx}, \frac{d^2y}{dx^2} \right) = 0$$

It can be reduced to a first-order equation by substituting  $p = dy/dx$  and  $dp/dx = d^2y/dx^2$ .

**Second-Order Equations: Independent Variable Missing** Such an equation is of the form

$$F \left( y, \frac{dy}{dx}, \frac{d^2y}{dx^2} \right) = 0$$

Set  $\frac{dy}{dx} = p$ ,  $\frac{d^2y}{dx^2} = p \frac{dp}{dy}$

The result is a first-order equation in  $p$ ,

$$F \left( y, p, p \frac{dp}{dy} \right) = 0$$

**Example** The capillary curve for one vertical plate is given by

$$\frac{d^2y}{dx^2} = \frac{4y}{c^2} \left[ 1 + \left( \frac{dy}{dx} \right)^2 \right]^{3/2}$$

Its solution by this technique is

$$x + \sqrt{c^2 - y^2} - \sqrt{c^2 - h_0^2} = \frac{c}{2} \left( \cosh^{-1} \frac{c}{y} - \cosh^{-1} \frac{c}{h_0} \right)$$

where  $c, h_0$  are physical constants.

**Example** The equation governing chemical reaction in a porous catalyst in plane geometry of thickness  $L$  is

$$D \frac{d^2c}{dx^2} = k f(c), \quad \frac{dc}{dx}(0) = 0, \quad c(L) = c_0$$

where  $D$  is a diffusion coefficient,  $k$  is a reaction rate parameter,  $c$  is the concentration,  $k f(c)$  is the rate of reaction, and  $c_0$  is the concentration at the

\*The superscript ( $n$ ) means  $n$  derivatives.

boundary. Making the substitution  $p = \frac{dc}{ds}$  gives (Finlayson, 1980, p. 92)

$$p \frac{dp}{dc} = \frac{k}{D} f(c)$$

Integrating gives

$$\frac{p^2}{2} = \frac{k}{D} \int_{c(0)}^c f(c) dc$$

If the reaction is very fast,  $c(0) = 0$  and the average reaction rate is related to  $p(L)$ . This variable is given by

$$p(L) = \left[ \frac{2k}{D} \int_0^{c_0} f(c) dc \right]^{1/2}$$

Thus, the average reaction rate can be calculated without solving the complete problem.

### Linear Nonhomogeneous Differential Equations

**Linear Differential Equations Right-Hand Member  $f(x) \neq 0$**   
 Again the specific remarks for  $y'' + ay' + by = f(x)$  apply to differential equations of similar type but higher order. We shall discuss two general methods.

**Method of Undetermined Coefficients** Use of this method is limited to equations exhibiting both constant coefficients and particular forms of the function  $f(x)$ . In most cases  $f(x)$  will be a sum or product of functions of the type constant,  $x^n$  ( $n$  a positive integer),  $e^{mx}$ ,  $\cos kx$ ,  $\sin kx$ . When this is the case, the solution of the equation is  $y = H(x) + P(x)$ , where  $H(x)$  is a solution of the homogeneous equations found by the method of the preceding subsection and  $P(x)$  is a particular integral found by using the following table subject to these conditions: (1) When  $f(x)$  consists of the sum of several terms, the appropriate form of  $P(x)$  is the sum of the particular integrals corresponding to these terms individually. (2) When a term in any of the trial integrals listed is already a part of the homogeneous solution, the indicated form of the particular integral is multiplied by  $x$ .

#### Form of Particular Integral

| If $f(x)$ is   | Then $P(x)$ is  |
|--|---|
| $a$ (constant)   | $A$ (constant)  |
| $ax^n$   | $A_n x^n + A_{n-1} x^{n-1} + \dots + A_1 x + A_0$                                 |
| $ae^{rx}$  | $Be^{rx}$   |
| $\left. \begin{matrix} c \cos kx \\ d \sin kx \end{matrix} \right\}$                       | $A \cos kx + B \sin kx$   |
| $\left. \begin{matrix} g x^n e^{rx} \cos kx \\ h x^n e^{rx} \sin kx \end{matrix} \right\}$ | $(A_n x^n + \dots + A_0) e^{rx} \cos kx + (B_n x^n + \dots + B_0) e^{rx} \sin kx$ |

Since the form of the particular integral is known, the constants may be evaluated by substitution in the differential equation.

**Example**  $y'' + 2y' + y = 3e^{2x} - \cos x + x^3$ . The characteristic equation is  $(m + 1)^2 = 0$  so that the homogeneous solution is  $y = (c_1 + c_2 x)e^{-x}$ . To find a particular solution we use the trial solution from the table,  $y = a_1 e^{2x} + a_2 \cos x + a_3 \sin x + a_4 x^3 + a_5 x^2 + a_6 x + a_7$ . Substituting this in the differential equation collecting and equating like terms, there results  $a_1 = 1/5$ ,  $a_2 = 0$ ,  $a_3 = -1/2$ ,  $a_4 = 1$ ,  $a_5 = -6$ ,  $a_6 = 18$ , and  $a_7 = -24$ . The solution is  $y = (c_1 + c_2 x)e^{-x} + 1/5 e^{2x} - 1/2 \sin x + x^3 - 6x^2 + 18x - 24$ .

**Method of Variation of Parameters** This method is applicable to any linear equation. The technique is developed for a second-order equation but immediately extends to higher order. Let the equation be  $y'' + a(x)y' + b(x)y = R(x)$  and let the solution of the homogeneous equation, found by some method, be  $y = c_1 f_1(x) + c_2 f_2(x)$ . It is now assumed that a particular integral of the differential equation is of the form  $P(x) = u f_1 + v f_2$  where  $u, v$  are functions of  $x$  to be determined by two equations. One equation results from the requirement that  $u f_1 + v f_2$  satisfy the differential equation, and the other is a degree of freedom open to the analyst. The best choice proves to be

$$u' f_1 + v' f_2 = 0 \quad \text{and} \quad u' f_1' + v' f_2' = R(x)$$

Then 
$$u' = \frac{du}{dx} = - \frac{f_2}{f_1 f_2' - f_2' f_1} R(x)$$

$$v' = \frac{dv}{dx} = \frac{f_1}{f_1 f_2' - f_2' f_1} R(x)$$

and since  $f_1, f_2$ , and  $R$  are known  $u, v$  may be found by direct integration.

**Perturbation Methods** If the ordinary differential equation has a parameter that is small and is not multiplying the highest derivative, perturbation methods can give solutions for small values of the parameter.

**Example** Consider the differential equation for reaction and diffusion in a catalyst; the reaction is second order:  $c'' = ac^2$ ,  $c'(0) = 0$ ,  $c(1) = 1$ . The solution is expanded in the following Taylor series in  $a$ .

$$c(x, a) = c_0(x) + ac_1(x) + a^2 c_2(x) + \dots$$

The goal is to find equations governing the functions  $\{c_i(x)\}$  and solve them. Substitution into the equations gives the following equations:

$$\begin{aligned} c_0''(x) + a c_0'(x) + a^2 c_0^2(x) + \dots &= a[c_0(x) + ac_1(x) + a^2 c_2(x) + \dots]^2 \\ c_0'(0) + ac_1'(0) + a^2 c_2'(0) + \dots &= 0 \\ c_0(1) + ac_1(1) + a^2 c_2(1) + \dots &= 1 \end{aligned}$$

Like terms in powers of  $a$  are collected to form the individual problems.

$$\begin{aligned} c_0'' &= 0, \quad c_0'(0) = 0, \quad c_0(1) = 1 \\ c_1'' &= c_0^2, \quad c_1'(0) = 0, \quad c_1(1) = 0 \\ c_2'' &= 2c_0 c_1, \quad c_2'(0) = 0, \quad c_2(1) = 0 \end{aligned}$$

The solution proceeds in turn.

$$c_0(x) = 1, \quad c_1(x) = \frac{(x^2 - 1)}{2}, \quad c_2(x) = \frac{5 - 6x^2 + x^4}{12}$$

### SPECIAL DIFFERENTIAL EQUATIONS [SEE ABRAMOWITZ AND STEGUN (1972)]

**Euler's Equation** The linear equation  $x^n y^{(n)} + a_n x^{n-1} y^{(n-1)} + \dots + a_{n-1} x y' + a_n y = R(x)$  can be reduced to a linear equation with constant coefficients by the change of variable  $x = e^r$ . To solve the homogeneous equation substitute  $y = x^r$  into it, cancel the powers of  $x$ , which are the same for all terms, and solve the resulting polynomial for  $r$ . In case of multiple or complex roots there results the form  $y = x^r (\log x)^r$  and  $y = x^{i\alpha} [\cos(\beta \log x) + i \sin(\beta \log x)]$ .

**Bessel's Equation** The linear equation  $x^2(d^2y/dx^2) + (1 - 2\alpha)x(dy/dx) + [\beta^2 \gamma^2 x^{2\gamma} + (\alpha^2 - p^2 \gamma^2)]y = 0$  is the general Bessel equation. By series methods, not to be discussed here, this equation can be shown to have the solution

$$\begin{aligned} y &= Ax^\alpha J_p(\beta x^\gamma) + Bx^\alpha J_{-p}(\beta x^\gamma) \quad p \text{ not an integer or zero} \\ y &= Ax^\alpha J_p(\beta x^\gamma) + Bx^\alpha Y_p(\beta x^\gamma) \quad p \text{ an integer} \end{aligned}$$

where  $J_p(x) = \left(\frac{x}{2}\right)^p \sum_{k=0}^{\infty} \frac{(-1)^k (x/2)^{2k}}{k! \Gamma(p+k+1)}$

$$J_{-p}(x) = \left(\frac{x}{2}\right)^{-p} \sum_{k=0}^{\infty} \frac{(-1)^k (x/2)^{2k}}{k! \Gamma(k+1-p)} \quad p \text{ not an integer}$$

$$\Gamma(n) = \int_0^{\infty} x^{n-1} e^{-x} dx \quad n > 0$$

is the gamma function. For  $p$  an integer

$$J_p(x) = \left(\frac{x}{2}\right)^p \sum_{k=0}^{\infty} \frac{(-1)^k (x/2)^{2k}}{k! (p+k)!}$$

(Bessel function of the first kind of order  $p$ )

$$Y_p(x) = \frac{[J_p(x) \cos(p\pi) - J_{-p}(x)]}{\sin(p\pi)}$$

(replace right-hand side by limiting value if  $p$  is an integer or zero).

The series converge for all  $x$ . Much of the importance of Bessel's equation and Bessel functions lies in the fact that the solutions of numerous linear differential equations can be expressed in terms of them.

**Legendre's Equation** The Legendre equation  $(1 - x^2)y'' - 2xy' + n(n + 1)y = 0$ ,  $n \geq 0$ , has the solution  $P_n$  for  $n$  an integer.

The polynomials  $P_n$  are the so-called Legendre polynomials,  $P_0(x) = 1$ ,  $P_1(x) = x$ ,  $P_2(x) = \frac{1}{2}(3x^2 - 1)$ ,  $P_3(x) = \frac{1}{2}(5x^3 - 3x)$ , . . .

For  $n$  positive and not an integer, see Abramowitz and Stegun (1972).

**Laguerre's Equation** The Laguerre equation  $x(d^2y/dx^2) + (c - x)(dy/dx) - ay = 0$  is satisfied by the confluent hypergeometric function. See Abramowitz and Stegun (1972) and Kreszig (1999).

**Hermite's Equation** The Hermite equation  $y'' - 2xy' + 2ny = 0$  is satisfied by the Hermite polynomial of degree  $n$ ,  $y = AH_n(x)$  if  $n$  is a positive integer or zero.  $H_0(x) = 1$ ,  $H_1(x) = 2x$ ,  $H_2(x) = 4x^2 - 2$ ,  $H_3(x) = 8x^3 - 12x$ ,  $H_4(x) = 16x^4 - 48x^2 + 12$ ,  $H_{r+1}(x) = 2xH_r(x) - 2rH_{r-1}(x)$ .

**Chebyshev's Equation** The equation  $(1 - x^2)y'' - xy' + n^2y = 0$  for  $n$  a positive integer or zero is satisfied by the  $n$ th Chebyshev polynomial  $y = AT_n(x)$ .  $T_0(x) = 1$ ,  $T_1(x) = x$ ,  $T_2(x) = 2x^2 - 1$ ,  $T_3(x) = 4x^3 - 3x$ ,  $T_4(x) = 8x^4 - 8x^2 + 1$ ;  $T_{r+1}(x) = 2xT_r(x) - T_{r-1}(x)$ .

**PARTIAL DIFFERENTIAL EQUATIONS**

The analysis of situations involving two or more independent variables frequently results in a partial differential equation.

**Example** The equation  $\partial T/\partial t = K(\partial^2 T/\partial x^2)$  represents the unsteady one-dimensional conduction of heat.

**Example** The equation for the unsteady transverse motion of a uniform beam clamped at the ends is

$$\frac{\partial^4 y}{\partial x^4} + \frac{\rho}{EI} \frac{\partial^2 y}{\partial t^2} = 0$$

**Example** The expansion of a gas behind a piston is characterized by the simultaneous equations

$$\frac{\partial u}{\partial t} + u \frac{\partial u}{\partial x} + \frac{c^2}{\rho} \frac{\partial \rho}{\partial x} = 0 \quad \text{and} \quad \frac{\partial \rho}{\partial t} + u \frac{\partial \rho}{\partial x} + \rho \frac{\partial u}{\partial x} = 0$$

The partial differential equation  $\partial^2 f/\partial x \partial y = 0$  can be solved by two integrations yielding the solution  $f = g(x) + h(y)$ , where  $g(x)$  and  $h(y)$  are arbitrary differentiable functions. This result is an example of the fact that the general solution of partial differential equations involves arbitrary functions in contrast to the solution of ordinary differential equations, which involve only arbitrary constants. A number of methods are available for finding the general solution of a partial differential equation. In most applications of partial differential equations the general solution is of limited use. In such applications the solution of a partial differential equation must satisfy both the equation and certain auxiliary conditions called **initial** and/or **boundary** conditions, which are dictated by the problem. Examples of these include those in which the wall temperature is a fixed constant  $T(x_0) = T_0$ , there is no diffusion across a nonpermeable wall, and the like. In ordinary differential equations these auxiliary conditions allow definite numbers to be assigned to the constants of integration.

**Partial Differential Equations of Second and Higher Order** Many of the applications to scientific problems fall naturally into partial differential equations of second order, although there are important exceptions in elasticity, vibration theory, and elsewhere.

A second-order differential equation can be written as

$$a \frac{\partial^2 u}{\partial x^2} + b \frac{\partial^2 u}{\partial x \partial y} + c \frac{\partial^2 u}{\partial y^2} = f$$

where  $a$ ,  $b$ ,  $c$ , and  $f$  depend upon  $x$ ,  $y$ ,  $u$ ,  $\partial u/\partial x$ , and  $\partial u/\partial y$ . This equation is hyperbolic, parabolic, or elliptic, depending on whether the discriminant  $b^2 - 4ac$  is  $>0$ ,  $=0$ , or  $<0$ , respectively. Since  $a$ ,  $b$ ,  $c$ , and  $f$  depend on the solution, the type of equation can be different at different  $x$  and  $y$  locations. If the equation is hyperbolic, discontinuities can be propagated. See Courant and Hilbert (1953, 1962) and LeVeque, R. J., *Numerical Methods for Conservation Laws*, Birkhäuser, Basel (1992).

Phenomena of **propagation** such as vibrations are characterized by equations of "hyperbolic" type which are essentially different in their

properties from other classes such as those which describe equilibrium (elliptic) or unsteady diffusion and heat transfer (parabolic). Prototypes are as follows:

**Elliptic** Laplace's equation  $\partial^2 u/\partial x^2 + \partial^2 u/\partial y^2 = 0$  and Poisson's equation  $\partial^2 u/\partial x^2 + \partial^2 u/\partial y^2 = g(x, y)$  do not contain the variable time explicitly and consequently represent equilibrium configurations. Laplace's equation is satisfied by static electric or magnetic potential at points free from electric charges or magnetic poles. Other important functions satisfying Laplace's equation are the velocity potential of the irrotational motion of an incompressible fluid, used in hydrodynamics; the steady temperature at points in a homogeneous solid, and the steady state of diffusion through a homogeneous body.

**Parabolic** The heat equation  $\partial T/\partial t = \partial^2 T/\partial x^2 + \partial^2 T/\partial y^2$  represents nonequilibrium or unsteady states of heat conduction and diffusion.

**Hyperbolic** The wave equation  $\partial^2 u/\partial t^2 = c^2(\partial^2 u/\partial x^2 + \partial^2 u/\partial y^2)$  represents wave propagation of many varied types.

Quasilinear first-order differential equations are like

$$a \frac{\partial u}{\partial x} + b \frac{\partial u}{\partial y} = f$$

where  $a$ ,  $b$ , and  $f$  depend on  $x$ ,  $y$ , and  $u$ , with  $a^2 + b^2 \neq 0$ . This equation can be solved using the method of characteristics, which writes the solution in terms of a parameter  $s$ , which defines a path for the characteristic.

$$\frac{dx}{ds} = a, \quad \frac{dy}{ds} = b, \quad \frac{du}{ds} = f$$

These equations are integrated from some initial conditions. For a specified value of  $s$ , the value of  $x$  and  $y$  shows the location where the solution is  $u$ . The equation is semilinear if  $a$  and  $b$  depend just on  $x$  and  $y$  (and not  $u$ ), and the equation is linear if  $a$ ,  $b$ , and  $f$  all depend on  $x$  and  $y$ , but not  $u$ . Such equations give rise to shock propagation, and conditions have been derived to deduce the presence of shocks. Courant and Hilbert (1953, 1962); Rhee, H. K., R. Aris, and N. R. Amundson, *First-Order Partial Differential Equations*, vol. I, *Theory and Applications of Single Equations*, Prentice-Hall, Englewood Cliffs, N.J. (1986); and LeVeque (1992), *ibid*.

An example of a linear hyperbolic equation is the advection equation for flow of contaminants when the  $x$  and  $y$  velocity components are  $u$  and  $v$ , respectively.

$$\frac{\partial c}{\partial t} + u \frac{\partial c}{\partial x} + v \frac{\partial c}{\partial y} = 0$$

The equations for flow and adsorption in a packed bed or chromatography column give a quasilinear equation.

$$\phi \frac{\partial c}{\partial t} + \phi u \frac{\partial c}{\partial x} + (1 - \phi) \frac{df}{dc} \frac{\partial c}{\partial t} = 0$$

Here  $n = f(c)$  is the relation between concentration on the adsorbent and fluid concentration.

The solution of problems involving partial differential equations often revolves about an attempt to reduce the partial differential equation to one or more ordinary differential equations. The solutions of the ordinary differential equations are then combined (if possible) so that the boundary conditions as well as the original partial differential equation are simultaneously satisfied. Three of these techniques are illustrated.

**Similarity Variables** The physical meaning of the term "similarity" relates to internal similitude, or self-similitude. Thus, similar solutions in boundary-layer flow over a horizontal flat plate are those for which the horizontal component of velocity  $u$  has the property that two velocity profiles located at different coordinates  $x$  differ only by a scale factor. The mathematical interpretation of the term similarity is a transformation of variables carried out so that a reduction in the number of independent variables is achieved. There are essentially two methods for finding similarity variables, "separation of variables" (not the classical concept) and the use of "continuous transformation groups." The basic theory is available in Ames (1965).

**Example** The equation  $\partial\theta/\partial x = (A/y)(\partial^2\theta/\partial y^2)$  with the boundary conditions  $\theta = 0$  at  $x = 0, y > 0; \theta = 0$  at  $y = \infty, x > 0; \theta = 1$  at  $y = 0, x > 0$  represents the nondimensional temperature  $\theta$  of a fluid moving past an infinitely wide flat plate immersed in the fluid. Turbulent transfer is neglected, as is molecular transport except in the  $y$  direction. It is now assumed that the equation and the boundary conditions can be satisfied by a solution of the form  $\theta = f(y/x^n) = f(u)$ , where  $\theta = 0$  at  $x = \infty$  and  $\theta = 1$  at  $u = 0$ . The purpose here is to replace the independent variables  $x$  and  $y$  by the single variable  $u$  when it is hoped that a value of  $n$  exists which will allow  $x$  and  $y$  to be completely eliminated in the equation. In this case since  $u = y/x^n$ , there results after some calculation  $\partial\theta/\partial x = -(nu/x)(d\theta/du)$ ,  $\partial^2\theta/\partial y^2 = (1/x^{2n})(d^2\theta/du^2)$ , and when these are substituted in the equation,  $-(1/x)nu(d\theta/du) = (1/x^{2n})(A/u)(d^2\theta/du^2)$ . For this to be a function of  $u$  only, choose  $n = 1/2$ . There results  $(d^2\theta/du^2) + (u^2/3A)(d\theta/du) = 0$ . Two integrations and use of the boundary conditions for this ordinary differential equation give the solution

$$\theta = \int_u^\infty \exp(-u^2/9A) du \Big/ \int_0^\infty \exp(-u^2/9A) du$$

**Group Method** The type of transformation can be deduced using group theory. For a complete exposition, see Ames (1965) and Hill, J. M., *Differential Equations and Group Methods for Scientists and Engineers*, CRC Press, New York (1992); a shortened version is in Finlayson (1980, 2003). Basically, a similarity transformation should be considered when one of the independent variables has no physical scale (perhaps it goes to infinity). The boundary conditions must also simplify (and combine) since each transformation leads to a differential equation with one fewer independent variable.

**Example** A similarity variable is found for the problem

$$\frac{\partial c}{\partial t} = \frac{\partial}{\partial x} \left( \frac{D(c)}{D} \frac{\partial c}{\partial x} \right), \quad c(0, t) = 1, \quad c(\infty, t) = 0, \quad c(x, 0) = 0$$

Note that the length dimension goes to infinity, so that there is no length scale in the problem statement; this is a clue to try a similarity transformation. The transformation examined here is

$$\bar{t} = a^\alpha t, \quad \bar{x} = a^\beta x, \quad \bar{c} = a^\gamma c$$

With this substitution, the equation becomes

$$a^{\alpha-\gamma} \frac{\partial \bar{c}}{\partial \bar{t}} = a^{2\beta-\gamma} \frac{\partial}{\partial \bar{x}} \left[ D(a^{-\gamma} \bar{c}) \frac{\partial \bar{c}}{\partial \bar{x}} \right]$$

Group theory says a system is conformally invariant if it has the same form in the new variables; here, that is

$$\gamma = 0, \quad \alpha - \gamma = 2\beta - \gamma, \quad \text{or } \alpha = 2\beta$$

The invariants are

$$\eta = \frac{x}{t^\beta}, \quad \delta = \frac{\beta}{\alpha}$$

and the solution is

$$c(x, t) = f(\eta)t^{\gamma/\alpha}$$

We can take  $\gamma = 0$  and  $\delta = \beta/\alpha = 1/2$ . Note that the boundary conditions combine because the point  $x = \infty$  and  $t = 0$  give the same value of  $\eta$  and the conditions on  $c$  at  $x = \infty$  and  $t = 0$  are the same. We thus make the transformation

$$\eta = \frac{x}{\sqrt{4D_0t}}, \quad c(x, t) = f(\eta)$$

The use of the 4 and  $D_0$  makes the analysis below simpler. The result is

$$\frac{d}{d\eta} \left[ \frac{D(c)}{D_0} \frac{df}{d\eta} \right] + 2\eta \frac{df}{d\eta} = 0, \quad f(0) = 1, \quad f(\infty) = 0$$

Thus, we solve a two-point boundary value problem instead of a partial differential equation. When the diffusivity is constant, the solution is the error function, a tabulated function.

$$c(x, t) = 1 - \operatorname{erf} \eta = \operatorname{erfc} \eta \\ \operatorname{erf} \eta = \int_0^\eta e^{-\xi^2} d\xi \Big/ \int_0^\infty e^{-\xi^2} d\xi$$

**Separation of Variables** This is a powerful, well-utilized method which is applicable in certain circumstances. It consists of assuming that the solution for a partial differential equation has the form  $U = f(x)g(y)$ . If it is then possible to obtain an ordinary differential equation on one side of the equation depending only on  $x$  and on the other side only on  $y$ , the partial differential equation is said to be

separable in the variables  $x, y$ . If this is the case, one side of the equation is a function of  $x$  alone and the other of  $y$  alone. The two can be equal only if each is a constant, say  $\lambda$ . Thus the problem has again been reduced to the solution of ordinary differential equations.

**Example** Laplace's equation  $\partial^2 V/\partial x^2 + \partial^2 V/\partial y^2 = 0$  plus the boundary conditions  $V(0, y) = 0, V(l, y) = 0, V(x, \infty) = 0, V(x, 0) = f(x)$  represents the steady-state potential in a thin plate (in  $z$  direction) of infinite extent in the  $y$  direction and of width  $l$  in the  $x$  direction. A potential  $f(x)$  is impressed (at  $y = 0$ ) from  $x = 0$  to  $x = l$ , and the sides are grounded. To obtain a solution of this boundary-value problem assume  $V(x, y) = f(x)g(y)$ . Substitution in the differential equation yields  $f''(x)g(y) + f(x)g''(y) = 0$ , or  $g''(y)/g(y) = -f''(x)/f(x) = \lambda^2$  (say). This system becomes  $g''(y) - \lambda^2 g(y) = 0$  and  $f''(x) + \lambda^2 f(x) = 0$ . The solutions of these ordinary differential equations are respectively  $g(y) = Ae^{\lambda y} + Be^{-\lambda y}, f(x) = C \sin \lambda x + D \cos \lambda x$ . Then  $f(0)g(y) = (Ae^{\lambda y} + Be^{-\lambda y})(C \sin \lambda x + D \cos \lambda x)$ . Now  $V(0, y) = 0$  so that  $f(0)g(y) = (Ae^{\lambda y} + Be^{-\lambda y})D = 0$  for all  $y$ . Hence  $D = 0$ . The solution then has the form  $\sin \lambda x (Ae^{\lambda y} + Be^{-\lambda y})$  where the multiplicative constant  $C$  has been eliminated. Since  $V(l, y) = 0, \sin \lambda l (Ae^{\lambda y} + Be^{-\lambda y}) = 0$ . Clearly the bracketed function of  $y$  is not zero, for the solution would then be the identically zero solution. Hence  $\sin \lambda l = 0$  or  $\lambda_n = n\pi/l, n = 1, 2, \dots$  where  $\lambda_n = n$ th eigenvalue.

The solution now has the form  $\sin(n\pi x/l)(Ae^{n\pi y/l} + Be^{-n\pi y/l})$ . Since  $V(x, \infty) = 0, A$  must be taken to be zero because  $e^y$  becomes arbitrarily large as  $y \rightarrow \infty$ . The solution then reads  $B_n \sin(n\pi x/l)e^{-n\pi y/l}$ , where  $B_n$  is the multiplicative constant. The differential equation is linear and homogeneous so that  $\sum_{n=1}^\infty B_n e^{-n\pi y/l} \sin(n\pi x/l)$  is also a solution. Satisfaction of the last boundary condition is ensured by taking

$$B_n = \frac{2}{l} \int_0^l f(x) \sin(n\pi x/l) dx = \text{Fourier sine coefficients of } f(x)$$

Further, convergence and differentiability of this series are established quite easily. Thus the solution is

$$V(x, y) = \sum_{n=1}^\infty B_n e^{-n\pi y/l} \sin \frac{n\pi x}{l}$$

**Example** The diffusion problem in a slab of thickness  $L$

$$\frac{\partial c}{\partial t} = D \frac{\partial^2 c}{\partial x^2}, \quad c(0, t) = 1, \quad c(L, t) = 0, \quad c(x, 0) = 0$$

can be solved by separation of variables. First transform the problem so that the boundary conditions are homogeneous (having zeros on the right-hand side). Let

$$c(x, t) = 1 - \frac{x}{L} + u(x, t)$$

Then  $u(x, t)$  satisfies

$$\frac{\partial u}{\partial t} = D \frac{\partial^2 u}{\partial x^2}, \quad u(x, 0) = \frac{x}{L} - 1, \quad u(0, t) = 0, \quad u(L, t) = 0$$

Assume a solution of the form  $u(x, t) = X(x)T(t)$ , which gives

$$\frac{1}{DT} \frac{dT}{dt} = \frac{1}{X} \frac{d^2 X}{dx^2}$$

Since both sides are constant, this gives the following ordinary differential equations to solve.

$$\frac{1}{DT} \frac{dT}{dt} = -\lambda, \quad \frac{1}{X} \frac{d^2 X}{dx^2} = -\lambda$$

The solution of these is

$$T = A e^{-\lambda Dt}, \quad X = B \cos \sqrt{\lambda} x + E \sin \sqrt{\lambda} x$$

The combined solution for  $u(x, t)$  is

$$u = A (B \cos \sqrt{\lambda} x + E \sin \sqrt{\lambda} x) e^{-\lambda Dt}$$

Apply the boundary condition that  $u(0, t) = 0$  to give  $B = 0$ . Then the solution is

$$u = A (\sin \sqrt{\lambda} x) e^{-\lambda Dt}$$

where the multiplicative constant  $E$  has been eliminated. Apply the boundary condition at  $x = L$ .

$$0 = A (\sin \sqrt{\lambda} L) e^{-\lambda Dt}$$

This can be satisfied by choosing  $A = 0$ , which gives no solution. However, it can also be satisfied by choosing  $\lambda$  such that

$$\sin \sqrt{\lambda} L = 0, \quad \sqrt{\lambda} L = n\pi$$

Thus

$$\lambda = \frac{n^2 \pi^2}{L^2}$$

### 3-34 MATHEMATICS

The combined solution can now be written as

$$u = A \left( \frac{\sin n\pi x}{L} \right) e^{-n^2\pi^2 D t / L^2}$$

Since the initial condition must be satisfied, we use an infinite series of these functions.

$$u = \sum_{n=1}^{\infty} A_n \left( \frac{\sin n\pi x}{L} \right) e^{-n^2\pi^2 D t / L^2}$$

At  $t = 0$ , we satisfy the initial condition.

$$\frac{x}{L} - 1 = \sum_{n=1}^{\infty} A_n \left( \frac{\sin n\pi x}{L} \right)$$

This is done by multiplying the equation by

$$\frac{\sin m\pi x}{L}$$

and integrating over  $x: 0 \rightarrow L$ . (This is the same as minimizing the mean-square error of the initial condition.) This gives

$$\frac{A_m L}{2} = \int_0^L \left( \frac{x}{L} - 1 \right) \sin \frac{m\pi x}{L} dx$$

which completes the solution.

**Integral-Transform Method** A number of integral transforms are used in the solution of differential equations. Only one, the Laplace transform, will be discussed here [for others, see "Integral Transforms (Operational Methods)"]. The one-sided Laplace transform indicated by  $L[f(t)]$  is defined by the equation  $L[f(t)] = \int_0^{\infty} f(t)e^{-st} dt$ . It has numerous important properties. The ones of interest here are  $L[f'(t)] = sL[f(t)] - f(0)$ ;  $L[f''(t)] = s^2L[f(t)] - sf(0) - f'(0)$ ;  $L[f^{(n)}(t)] = s^nL[f(t)] - s^{n-1}f(0) - s^{n-2}f'(0) - \dots - f^{(n-1)}(0)$  for ordinary derivatives. For partial derivatives an indication of which variable is being transformed avoids confusion. Thus, if

$$y = y(x, t), \quad L_t \left[ \frac{\partial y}{\partial t} \right] = sL[y(x, t)] - y(x, 0)$$

whereas

$$L_x \left[ \frac{\partial y}{\partial x} \right] = \frac{dL_x[y(x, t)]}{dx}$$

since  $L[y(x, t)]$  is "really" only a function of  $x$ . Otherwise the results are similar. These facts coupled with the linearity of the transform, i.e.,  $L[af(t) + bg(t)] = aL[f(t)] + bL[g(t)]$ , make it a useful device in solving some linear differential equations. Its use reduces the solution of ordinary differential equations to the solution of algebraic equations for  $L[y]$ . The inverse transform must be obtained either from tables or by use of complex inversion methods.

**Example** The equation  $\partial c / \partial t = D(\partial^2 c / \partial x^2)$  represents the diffusion in a semi-infinite medium,  $x \geq 0$ . Under the boundary conditions  $c(0, t) = c_0$ ,  $c(x, 0) = 0$  find a solution of the diffusion equation. By taking the Laplace transform of both sides with respect to  $t$ ,

$$\int_0^{\infty} e^{-st} \frac{\partial^2 c}{\partial x^2} dt = \frac{1}{D} \int_0^{\infty} e^{-st} \frac{\partial c}{\partial t} dt$$

$$\text{or} \quad \frac{d^2 F}{dx^2} = (1/D)sF - c(x, 0) = \frac{sF}{D}$$

where  $F(x, s) = L_t[c(x, t)]$ . Hence

$$\frac{d^2 F}{dx^2} - \left( \frac{s}{D} \right) F = 0$$

The other boundary condition transforms into  $F(0, s) = c_0/s$ . Finally the solution of the ordinary differential equation for  $F$  subject to  $F(0, s) = c_0/s$  and  $F$  remains finite as  $x \rightarrow \infty$  is  $F(x, s) = (c_0/s)e^{-\sqrt{s/D}x}$ . Reference to a table shows that the function having this as its Laplace transform is

$$c(x, t) = c_0 \left[ 1 - \frac{2}{\sqrt{\pi}} \int_0^{x/\sqrt{4Dt}} e^{-u^2} du \right] = C_0 \operatorname{erfc} \left( \frac{x}{\sqrt{4Dt}} \right)$$

**Matched-Asymptotic Expansions** Sometimes the coefficient in front of the highest derivative is a small number. Special perturbation techniques can then be used, provided the proper scaling laws are found. See Kevorkian, J., and J. D. Cole, *Perturbation Methods in Applied Mathematics*, Springer-Verlag, New York (1981); and Lagerstrom, P. A., *Matched Asymptotic Expansions: Ideas and Techniques*, Springer-Verlag, New York (1988).

## DIFFERENCE EQUATIONS

**REFERENCES:** Elaydi, Saber, and S. N. Elaydi, *An Introduction to Difference Equations*, Springer-Verlag, New York (1999); Fulford, G., P. Forrester, and A. Jones, *Modelling with Differential and Difference Equations*, Cambridge University Press, New York (1997); Goldberg, S., *Introduction to Difference Equations*, Dover (1986); Kelley, W. G., and A. C. Peterson, *Difference Equations: An Introduction with Applications*, 2d ed., Harcourt/Academic Press, San Diego (2001).

Certain situations are such that the independent variable does not vary continuously but has meaning only for discrete values. Typical illustrations occur in the stagewise processes found in chemical engineering such as distillation, staged extraction systems, and absorption columns. In each of these the operation is characterized by a finite between-stage change of the dependent variable in which the independent variable is the integral number of the stage. The importance of difference equations is twofold: (1) to analyze problems of the type described and (2) to obtain approximate solutions of problems which lead, in their formulation, to differential equations. In this subsection only problems of analysis are considered; the application to approximate solutions is considered under "Numerical Analysis and Approximate Methods."

### ELEMENTS OF THE CALCULUS OF FINITE DIFFERENCES

Let  $y = f(x)$  be defined for discrete equidistant values of  $x$ , which will be denoted by  $x_n$ . The corresponding value of  $y$  will be written  $y_n = f(x_n)$ . The first forward difference of  $f(x)$  denoted by  $\Delta f(x) = f(x+h) - f(x)$  where  $h = x_n - x_{n-1} =$  interval length.

**Example** Let  $f(x) = x^2$ . Then  $\Delta f(x) = (x+h)^2 - x^2 = 2hx + h^2$ .

The second forward difference is obtained by taking the difference of the first; thus  $\Delta^2 f(x) = \Delta^2 f(x) = \Delta f(x+h) - \Delta f(x) = f(x+2h) - 2f(x+h) + f(x)$ .

**Example**  $f(x) = x^2$ ,  $\Delta^2 f(x) = \Delta[\Delta f(x)] = \Delta 2hx + \Delta h^2 = 2h(x+h) - 2hx + h^2 - h^2 = 2h^2$ .

Similarly the  $n$ th forward difference is defined by the relation  $\Delta^n f(x) = \Delta[\Delta^{n-1} f(x)]$ . Other difference relations are also quite useful. Some of these are  $\nabla f(x) = f(x) - f(x-h)$ , which is called the backward difference, and  $\delta f(x) = f[x+(h/2)] - f[x-(h/2)]$ , called the central difference. Some properties of the operator  $\Delta$  are quite important. If  $C$  is any constant,  $\Delta C = 0$ ; if  $f(x)$  is any function of period  $h$ ,  $\Delta f(x) = 0$  (in fact, periodic functions of period  $h$  play the same role here as constants do in the differential calculus);  $\Delta[f(x) + g(x)] = \Delta f(x) + \Delta g(x)$ ;  $\Delta^n[\Delta^m f(x)] = \Delta^{m+n} f(x)$ ;  $\Delta[f(x)g(x)] = f(x)\Delta g(x) + g(x+h)\Delta f(x)$

$$\Delta \left[ \frac{f(x)}{g(x)} \right] = \frac{g(x)\Delta f(x) - f(x)\Delta g(x)}{g(x)g(x+h)}$$

**Example**  $\Delta(x \sin x) = x\Delta \sin x + \sin(x+h)\Delta x = 2x \sin(h/2) \cos[x+(h/2)] + h \sin(x+h)$ .

### DIFFERENCE EQUATIONS

A difference equation is a relation between the differences and the independent variable,  $\phi(\Delta^n y, \Delta^{n-1} y, \dots, \Delta y, y, x) = 0$ , where  $\phi$  is some

given function. The general case in which the interval between the successive points is any real number  $h$ , instead of 1, can be reduced to that with interval size 1 by the substitution  $x = hx'$ . Hence all further difference-equation work will assume the interval size between successive points is 1.

**Example**  $f(x+1) - (\alpha + 1)f(x) + \alpha f(x-1) = 0$ . Common notation usually is  $y_x = f(x)$ . This equation is then written  $y_{x+1} - (\alpha + 1)y_x + \alpha y_{x-1} = 0$ .

**Example**  $y_{x+2} + 2y_x y_{x+1} + y_x = x^2$ .

**Example**  $y_{x+1} - y_x = 2^x$ .

The order of the difference equation is the difference between the largest and smallest arguments when written in the form of the second example. The first and second examples are both of order 2, while the third example is of order 1. A linear difference equation involves no products or other nonlinear functions of the dependent variable and its differences. The first and third examples are linear, while the second example is nonlinear.

A solution of a difference equation is a relation between the variables which satisfies the equation. If the difference equation is of order  $n$ , the general solution involves  $n$  arbitrary constants. The techniques for solving difference equations resemble techniques used for differential equations.

**Equation  $\Delta^n y = a$**  The solution of  $\Delta^n y = a$ , where  $a$  is a constant, is a polynomial of degree  $n$  plus an arbitrary periodic function of period 1. That is,  $y = (a^n n! / \Gamma(n)) + c_1 x^{n-1} + c_2 x^{n-2} + \dots + c_n + f(x)$ , where  $f(x+1) = f(x)$ .

**Example**  $\Delta^3 y = 6$ . The solution is  $y = x^3 + c_1 x^2 + c_2 x + c_3 + f(x)$ ;  $c_1, c_2, c_3$  are arbitrary constants, and  $f(x)$  is an arbitrary periodic function of period 1.

**Equation  $y_{x+1} - y_x = \phi(x)$**  This equation states that the first difference of the unknown function is equal to the given function  $\phi(x)$ . The solution by analogy with solving the differential equation  $dy/dx = \phi(x)$  by integration is obtained by "finite integration" or summation. When there are only a finite number of data points, this is easily accomplished by writing  $y_x = y_0 + \sum_{t=1}^x \phi(t-1)$ , where the data points are numbered from 1 to  $x$ . This is the only situation considered here.

**Examples** If  $\phi(x) = 1, y_x = x$ . If  $\phi(x) = x, y_x = [x(x-1)]/2$ . If  $\phi(x) = a^x, a \neq 0, y_x = a^x/(a-1)$ . In all cases  $y_0 = 0$ .

Other examples may be evaluated by using summation, that is,  $y_2 = y_1 + \phi(1), y_3 = y_2 + \phi(2) = y_1 + \phi(1) + \phi(2), y_4 = y_3 + \phi(3) = y_1 + \phi(1) + \phi(2) + \phi(3), \dots, y_x = y_1 + \sum_{t=1}^{x-1} \phi(t)$ .

**Example**  $y_{x+1} - r y_x = 1, r$  constant,  $x > 0$  and  $y_0 = 1, y_1 = 1 + r, y_2 = 1 + r + r^2, \dots, y_x = 1 + r + \dots + r^x = (1 - r^{x+1})/(1 - r)$  for  $r \neq 1$  and  $y_x = 1 + x$  for  $r = 1$ .

**Linear Difference Equations** The linear difference equation of order  $n$  has the form  $P_n y_{x+n} + P_{n-1} y_{x+n-1} + \dots + P_1 y_{x+1} + P_0 y_x = Q(x)$  with  $P_n \neq 0$  and  $P_0 \neq 0$  and  $P_j, j = 0, \dots, n$  are functions of  $x$ .

**Constant Coefficient and  $Q(x) = 0$  (Homogeneous)** The solution is obtained by trying a solution of the form  $y_x = c\beta^x$ . When this trial solution is substituted in the difference equation, a polynomial of degree  $n$  results for  $\beta$ . If the solutions of this polynomial are denoted by  $\beta_1, \beta_2, \dots, \beta_n$  then the following cases result: (1) if all the  $\beta_j$ 's are real and unequal, the solution is  $y_x = \sum_{j=1}^n c_j \beta_j^x$ , where the  $c_1, \dots, c_n$  are arbitrary constants; (2) if the roots are real and repeated, say,  $\beta_1$  has multiplicity  $m$ , then the partial solution corresponding to  $\beta_1$  is  $\beta_1^x(c_1 + c_2 x + \dots + c_m x^{m-1})$ ; (3) if the roots are complex conjugates, say,  $a + ib = \rho e^{i\theta}$  and  $a - ib = \rho e^{-i\theta}$ , the partial solution corresponding to this pair is  $\rho^x(c_1 \cos \theta x + i c_2 \sin \theta x)$ ; and (4) if the roots are multiple complex conjugates, say,  $a + ib = \rho e^{i\theta}$  and  $a - ib = \rho e^{-i\theta}$  are  $m$ -fold, then the partial solution corresponding to these is  $\rho^x[(c_1 + c_2 x + \dots + c_m x^{m-1}) \cos \theta x + i(d_1 + d_2 x + \dots + d_m x^{m-1}) \sin \theta x]$ .

**Example** The equation  $y_{x+1} - (\alpha + 1)y_x + \alpha y_{x-1} = 0, y_0 = c_0$  and  $y_{m+1} = x_{m+1}/k$  represents the steady-state composition of transferable material in the raffinate stream of a staged countercurrent liquid-liquid extraction system.

Clearly  $y$  is a function of the stage number  $x$ .  $\alpha$  is a combination of system constants. By using the trial solution  $y_x = c\beta^x$ , there results  $\beta^2 - (\alpha + 1)\beta + \alpha = 0$ , so that  $\beta_1 = 1, \beta_2 = \alpha$ . The general solution is  $y_x = c_1 + c_2 \alpha^x$ . By using the side conditions,  $c_1 = c_0 - c_2, c_2 = (y_{m+1} - c_0)/(\alpha^{m+1} - 1)$ . The desired solution is  $(y_x - c_0)/(y_{m+1} - c_0) = (\alpha^x - 1)/(\alpha^{m+1} - 1)$ .

**Example**  $y_{x+3} - 3y_{x+2} + 4y_x = 0$ . By setting  $y_x = c\beta^x$ , there results  $\beta^3 - 3\beta^2 + 4 = 0$  or  $\beta_1 = -1, \beta_2 = 2, \beta_3 = 2$ . The general solution is  $y_x = c_1(-1)^x + 2^x(c_2 + c_3 x)$ .

**Example**  $y_{x+1} - 2y_x + 2y_{x-1} = 0, \beta_1 = 1 + i, \beta_2 = 1 - i, p = \sqrt{1+1} = \sqrt{2}, \theta = \pi/4$ . The solution is  $y_x = 2^{x/2}[c_1 \cos(x\pi/4) + i c_2 \sin(x\pi/4)]$ .

**Constant Coefficients and  $Q(x) \neq 0$  (Nonhomogeneous)** In this case the general solution is found by first obtaining the homogeneous solution, say,  $y_x^h$  and adding to it any particular solution with  $Q(x) \neq 0$ , say,  $y_x^p$ . There are several means of obtaining the particular solution.

**Method of Undetermined Coefficients** If  $Q(x)$  is a product or linear combination of products of the functions  $e^{bx}, a^x, x^p$  ( $p$  a positive integer or zero)  $\cos cx$  and  $\sin cx$ , this method may be used. The "families"  $[a^x], [e^{bx}], [\sin cx, \cos cx]$  and  $[x^p, x^{p-1}, \dots, x, 1]$  are defined for each of the above functions in the following way: The family of a term  $f_x$  is the set of all functions of which  $f_x$  and all operations of the form  $a^{x+y}, \cos c(x+y), \sin c(x+y), (x+y)^p$  on  $f_x$  and their linear combinations result in. The technique involves the following steps: (1) Solve the homogeneous system. (2) Construct the family of each term. (3) If the family has no representative in the homogeneous solution, assume  $y_x^p$  is a linear combination of the families of each term and determine the constants so that the equation is satisfied. (4) If a family has a representative in the homogeneous solution, multiply each member of the family by the smallest integral power of  $x$  for which all such representatives are removed and revert to step 3.

**Example**  $y_{x+1} - 3y_x + 2y_{x-1} = 1 + a^x, a \neq 0$ . The homogeneous solution is  $y_x^h = c_1 + c_2 2^x$ . The family of 1 is 1 and of  $a^x$  is  $a^x$ . However, 1 is a solution of the homogeneous system. Therefore, try  $y_x^p = Ax + Ba^x$ . Substituting in the equation there results

$$y_x = c_1 + c_2 2^x - x + \frac{a}{(a-1)(a-2)} a^x, a \neq 1, a \neq 2$$

If  $a = 1, y_x = c_1 + c_2 2^x - 2x$ . If  $a = 2, y_x = c_1 + c_2 2^x - x + x 2^x$ .

**Example** The family of  $x^2 3^x$  is  $[x^2 3^x, x 3^x, 3^x]$ .

**Method of Variation of Parameters** This technique is applicable to general linear difference equations. It is illustrated for the second-order system  $y_{x+2} + A y_{x+1} + B y_x = \phi(x)$ . Assume that the homogeneous solution has been found by some technique and write  $y_x^h = c_1 u_x + c_2 v_x$ . Assume that a particular solution  $y_x^p = D_x u_x + E_x v_x$ .  $E_x$  and  $D_x$  can be found by solving the equations:

$$E_{x+1} - E_x = \frac{u_{x+1} \phi(x)}{u_{x+1} v_{x+2} - u_{x+2} v_{x+1}}$$

$$D_{x+1} - D_x = \frac{v_{x+1} \phi(x)}{v_{x+1} u_{x+2} - v_{x+2} u_{x+1}}$$

by summation. The general solution is then  $y_x = y_x^p + y_x^h$ .

**Variable Coefficients** The method of variation of parameters applies equally well to the linear difference equation with variable coefficients. Techniques are therefore needed to solve the homogeneous system with variable coefficients.

**Equation  $y_{x+1} - a_x y_x = 0$**  By assuming that this equation is valid for  $x \geq 0$  and  $y_0 = c$ , the solution is  $y_x = c \prod_{n=1}^x a_{n-1}$ .

**Example**  $y_{x+1} + \frac{x+2}{x+1} y_x = 0$ . The solution is

$$y_x = c \prod_{n=1}^x \left( -\frac{n+1}{n} \right) = c(-1)^x \frac{2}{1} \cdot \frac{3}{2} \cdot \dots \cdot \frac{x+1}{x} = (-1)^x c(x+1)$$

**Example**  $y_{x+1} - x y_x = 0$ . The solution is  $y_x = c(x-1)!$

**Reduction of Order** If one homogeneous solution, say,  $u_x$ , can be found by inspection or otherwise, an equation of lower order can be obtained by the substitution  $v_x = y_x/u_x$ . The resultant equation must be satisfied by  $v_x = \text{constant}$  or  $\Delta v_x = 0$ . Thus the equation will be of reduced order if the new variable  $U_x = \Delta(y_x/u_x)$  is introduced.

**Example**  $(x + 2)y_{x+2} - (x + 3)y_{x+1} + y_x = 0$ . By observation  $u_x = 1$  is a solution. Set  $U_x = \Delta y_x = y_{x+1} - y_x$ . There results  $(x + 2)U_{x+1} - U_x = 0$ , which is of degree one lower than the original equation. The complete solution for  $y_x$  is finally

$$y_x = c_0 \sum_{n=0}^x \frac{1}{n!} + c_1$$

**Factorization** If the difference equation can be factored, then the general solution can be obtained by solving two or more successive equations of lower order. Consider  $y_{x+2} + A_x y_{x+1} + B_x y_x = \phi(x)$ . If there exists  $a_x, b_x$  such that  $a_x + b_x = -A_x$  and  $a_x b_x = B_x$ , then the difference equation may be written  $y_{x+2} - (a_x + b_x)y_{x+1} + a_x b_x y_x = \phi(x)$ . First solve  $U_{x+1} - b_x U_x = \phi(x)$  and then  $y_{x+1} - a_x y_x = U_x$ .

**Example**  $y_{x+2} - (2x + 1)y_{x+1} + (x^2 + x)y_x = 0$ . Set  $a_x = x, b_x = x + 1$ . Solve  $u_{x+1} - (x + 1)u_x = 0$  and then  $y_{x+1} - x y_x = u_x$ .

**Substitution** If it is possible to rearrange a difference equation so that it takes the form  $a_x y_{x+2} + b_x y_{x+1} + c_x y_x = \phi(x)$  with  $a, b, c$  constants, then the substitution  $u_x = f_x y_x$  reduces the equation to one with constant coefficients.

**Example**  $(x + 2)^2 y_{x+2} - 3(x + 1)^2 y_{x+1} + 2x^2 y_x = 0$ . Set  $u_x = x^2 y_x$ . The equation becomes  $u_{x+2} - 3u_{x+1} + 2u_x = 0$ , which is linear and easily solved by previous methods.

The substitution  $u_x = y_x/f_x$  reduces  $a_x f_x y_{x+2} + b_x f_x y_{x+1} + c_x f_x y_x = \phi(x)$  to an equation with constant coefficients.

**Example**  $x(x + 1)y_{x+2} + 3x(x + 2)y_{x+1} - 4(x + 1)(x + 2)y_x = x$ . Set  $u_x = y_x/f_x = y_x/x$ . Then  $y_x = x u_x, y_{x+1} = (x + 1)u_{x+1}$  and  $y_{x+2} = (x + 2)u_{x+2}$ . Substitution in the equation yields  $x(x + 1)(x + 2)u_{x+2} + 3x(x + 2)(x + 1)u_{x+1} - 4x(x + 1)(x + 2)u_x = x$  or  $u_{x+2} + 3u_{x+1} - 4u_x = 1/(x + 1)(x + 2)$ , which is a linear equation with constant coefficients.

**Nonlinear Difference Equations: Riccati Difference Equation** The Riccati equation  $y_{x+1} y_x + a y_{x+1} + b y_x + c = 0$  is a nonlinear difference equation which can be solved by reduction to linear form. Set  $y = z + h$ . The equation becomes  $z_{x+1} z_x + (h + a)z_{x+1} + (h + b)z_x + h^2 + (a + b)h + c = 0$ . If  $h$  is selected as a root of  $h^2 + (a + b)h + c = 0$  and the equation is divided by  $z_{x+1} z_x$  there results  $[(h + b)/z_{x+1}] + [(h + a)/z_x] + 1 = 0$ . This is a linear equation with constant coefficients. The solution is

$$y_x = h + \frac{1}{c \left[ \frac{a+h}{b+h} \right]^x - \frac{1}{(a+h) + (b+h)}}$$

**Example** This equation is obtained in distillation problems, among others, in which the number of theoretical plates is required. If the relative volatility is assumed to be constant, the plates are theoretically perfect, and the molal liquid and vapor rates are constant, then a material balance around the  $n$ th plate of the enriching section yields a Riccati difference equation.

## INTEGRAL EQUATIONS

**REFERENCES:** Courant, R., and D. Hilbert, *Methods of Mathematical Physics*, vol. I, Interscience, New York (1953); Linz, P., *Analytical and Numerical Methods for Volterra Equations*, SIAM Publications, Philadelphia (1985); Porter, D., and D. S. G. Stirling, *Integral Equations: A Practical Treatment from Spectral Theory to Applications*, Cambridge University Press (1990); Stogdole, I., *Green's Functions and Boundary Value Problems*, 2d ed., Interscience, New York (1997).

An integral equation is any equation in which the unknown function appears under the sign of integration and possibly outside the sign of integration. If derivatives of the dependent variable appear elsewhere in the equation, the equation is said to be integrodifferential.

### CLASSIFICATION OF INTEGRAL EQUATIONS

Volterra integral equations have an integral with a variable limit. The Volterra equation of the second kind is

$$u(x) = f(x) + \lambda \int_a^x K(x, t)u(t) dt$$

whereas a Volterra equation of the first kind is

$$u(x) = \lambda \int_a^x K(x, t)u(t) dt$$

Equations of the first kind are very sensitive to solution errors so that they present severe numerical problems. Volterra equations are similar to initial value problems.

A Fredholm equation of the second kind is

$$u(x) = f(x) + \lambda \int_a^b K(x, t)u(t) dt$$

whereas a Fredholm equation of the first kind is

$$u(x) = \int_a^b K(x, t)u(t) dt$$

The limits of integration are fixed, and these problems are analogous to boundary value problems.

An eigenvalue problem is a homogeneous equation of the second kind, and solutions exist only for certain  $\lambda$ .

$$u(x) = \lambda \int_a^b K(x, t)u(t) dt$$

See Linz (1985) for further information and existence proofs.

If the unknown function  $u$  appears in the equation in any way except to the first power, the integral equation is said to be nonlinear. The equation  $u(x) = f(x) + \int_a^b K(x, t)[u(t)]^{3/2} dt$  is nonlinear. The differential equation  $du/dx = g(x, u)$  is equivalent to the nonlinear integral equation  $u(x) = c + \int_a^x g[t, u(t)] dt$ .

An integral equation is said to be singular when either one or both of the limits of integration become infinite or if  $K(x, t)$  becomes infinite for one or more points of the interval under discussion.

**Example**  $u(x) = x + \int_0^\infty \cos(xt)u(t) dt$  and  $f(x) = \int_0^x \frac{u(t)}{x-t} dt$  are both singular. The kernel of the first equation is  $\cos(xt)$ , and that of the second is  $(x-t)^{-1}$ .

### RELATION TO DIFFERENTIAL EQUATIONS

The Leibniz rule (see "Integral Calculus") can be used to show the equivalence of the initial-value problem consisting of the second-order differential equation  $d^2y/dx^2 + A(x)(dy/dx) + B(x)y = f(x)$  together with the prescribed initial conditions  $y(a) = y_0, y'(a) = y'_0$  to the integral equation.

$$y(x) = \int_a^x K(x, t)y(t) dt + F(x)$$

where  $K(x, t) = (t-x)[B(t) - A'(t)] - A(t)$

and 
$$F(x) = \int_a^x (x-t)f(t) dt + [A(a)y_0 + y_0'](x-a) + y_0$$

This integral equation is a **Volterra equation** of the second kind. Thus the initial-value problem is equivalent to a Volterra integral equation of the second kind.

**Example**  $d^2y/dx^2 + x^2(dy/dx) + xy = x, y(0) = 1, y'(0) = 0$ . Here  $A(x) = x^2, B(x) = x, f(x) = x$ . The equivalent integral equation is  $y(x) = \int_0^x K(x, t)y(t) dt + F(x)$  where  $K(x, t) = t(x-t) - t^2$  and  $F(x) = \int_0^x (x-t)t dt + 1 = x^3/6 + 1$ . Combining these  $y(x) = \int_0^x t[x - 2t]y(t) dt + x^3/6 + 1$ .

Eigenvalue problems can also be related. For example, the problem  $(d^2y/dx^2) + \lambda y = 0$  with  $y(0) = 0, y(a) = 0$  is equivalent to the integral equation  $y(x) = \lambda \int_0^a K(x, t)y(t) dt$ , where  $K(x, t) = (t/a)(a-x)$  when  $t < x$  and  $K(x, t) = (x/a)(a-t)$  when  $t > x$ . The differential equation may be recovered from the integral equation by differentiating the integral equation by using the Leibniz rule.

**METHODS OF SOLUTION**

In general, the solution of integral equations is not easy, and a few exact and approximate methods are given here. Often numerical methods must be employed, as discussed in "Numerical Solution of Integral Equations."

**Equations of Convolution Type** The equation  $u(x) = f(x) + \lambda \int_0^x K(x-t)u(t) dt$  is a special case of the linear integral equation of the second kind of Volterra type. The integral part is the convolution integral discussed under "Integral Transforms (Operational Methods)"; so the solution can be accomplished by Laplace transforms;  $L[u(x)] = L[f(x)] + \lambda L[u(x)]L[K(x)]$  or

$$L[u(x)] = \frac{L[f(x)]}{1 - \lambda L[K(x)]}, \quad u(x) = L^{-1} \left[ \frac{L[f(x)]}{1 - \lambda L[K(x)]} \right]$$

**INTEGRAL TRANSFORMS (OPERATIONAL METHODS)**

**REFERENCES:** Brown, J. W., and R. V. Churchill, *Fourier Series and Boundary Value Problems*, 6th ed., McGraw-Hill, New York (2000); Churchill, R. V., *Operational Mathematics*, 3d ed., McGraw-Hill, New York (1972); Davies, B., *Integral Transforms and Their Applications*, 3d ed., Springer (2002); Duffy, D. G., *Transform Methods for Solving Partial Differential Equations*, Chapman & Hall/CRC, New York (2004); Varma, A., and M. Morbidelli, *Mathematical Methods in Chemical Engineering*, Oxford, New York (1997).

The term "operational method" implies a procedure of solving differential and difference equations by which the boundary or initial conditions are automatically satisfied in the course of the solution. The technique offers a very powerful tool in the applications of mathematics, but it is limited to linear problems.

Most integral transforms are special cases of the equation  $g(s) = \int_a^b f(t)K(s, t) dt$  in which  $g(s)$  is said to be the transform of  $f(t)$  and  $K(s, t)$  is called the kernel of the transform. A tabulation of the more important kernels and the interval  $(a, b)$  of applicability follows. The first three transforms are considered here.

| Name of transform | $(a, b)$            | $K(s, t)$                        |
|-------------------|---------------------|----------------------------------|
| Laplace           | $(0, \infty)$       | $e^{-st}$                        |
| Fourier           | $(-\infty, \infty)$ | $\frac{1}{\sqrt{2\pi}} e^{-ist}$ |
| Fourier cosine    | $(0, \infty)$       | $\sqrt{\frac{2}{\pi}} \cos st$   |
| Fourier sine      | $(0, \infty)$       | $\sqrt{\frac{2}{\pi}} \sin st$   |
| Mellin            | $(0, \infty)$       | $t^{s-1}$                        |
| Hankel            | $(0, \infty)$       | $tJ_\nu(st), \nu \geq -1/2$      |

Equations of the type considered here occur quite frequently in practice in what can be called "cause-and-effect" systems.

**Example** In a certain linear system, the effect  $E(t)$  due to a cause  $C = \lambda E$  at time  $\tau$  is a function only of the elapsed time  $t - \tau$ . If the system has the activity level 1 at time  $t < 0$ , the cause  $\lambda E$  and effect ( $E$ ) relation is given by the integral equation  $E(t) = 1 + \lambda \int_0^t K(t - \tau)E(\tau) d\tau$ . Let  $K(t - \tau) = t - \tau$ . Then  $E(t) = 1 + \lambda \int_0^t (t - \tau)E(\tau) d\tau$ . By using the transform method

$$E(t) = L^{-1} \left[ \frac{L[1]}{1 - \lambda L[K(t)]} \right] = L^{-1} \left[ \frac{1/p}{1 - \lambda/p^2} \right] = L^{-1} \left[ \frac{p}{p^2 - \lambda} \right] = \cosh \sqrt{\lambda} t$$

**Method of Successive Approximations** Consider the equation  $y(x) = f(x) + \lambda \int_a^b K(x, t)y(t) dt$ . In this method a unique solution is obtained in sequence form as follows: Substitute in the right-hand member of the equation  $y_0(t)$  for  $y(t)$ . Upon integration there results  $y_1(t) = f(x) + \lambda \int_a^b K(x, t)y_0(t) dt$ . Continue in like manner by replacing  $y_0$  by  $y_1, y_1$  by  $y_2$ , etc. A series of functions  $y_0(x), y_1(x), y_2(x), \dots$  are obtained which satisfy the equations

$$y_n(x) = f(x) + \lambda \int_a^b K(x, t)y_{n-1}(t) dt$$

Then  $y_n(x) = f(x) + \lambda \int_a^b K(x, t)f(t) dt + \lambda^2 \int_a^b K(x, t) \int_a^b K(t, t_1) f(t_1) dt_1 dt + \lambda^3 \int_a^b K(x, t) \int_a^b K(t, t_1) \int_a^b K(t_1, t_2) f(t_2) dt_2 dt_1 dt + \dots + R_n$ , where  $R_n$  is the remainder, and

$$|R_n| \leq |\lambda|^n \left( \max_{a \leq x \leq b} y_0 \right) M^n (b-a)^n$$

where  $M$  = maximum value of  $|K|$  in the rectangle  $a \leq t \leq b, a \leq x \leq b$ . If  $|\lambda|M(b-a) < 1, \lim_{n \rightarrow \infty} R_n = 0$ . Then  $y_n(x) \rightarrow y(x)$ , which is the unique solution.

**LAPLACE TRANSFORM**

The Laplace transform of a function  $f(t)$  is defined by  $F(s) = L\{f(t)\} = \int_0^\infty e^{-st}f(t) dt$ , where  $s$  is a complex variable. Note that the transform is an improper integral and therefore may not exist for all continuous functions and all values of  $s$ . We restrict consideration to those values of  $s$  and those functions  $f$  for which this improper integral converges. The Laplace transform is used in process control (see Sec. 8).

The function  $L\{f(t)\} = g(s)$  is called the direct transform, and  $L^{-1}\{g(s)\} = f(t)$  is called the inverse transform. Both the direct and the inverse transforms are tabulated for many often-occurring functions. In general,

$$L^{-1}\{g(s)\} = \frac{1}{2\pi i} \int_{\alpha - i\infty}^{\alpha + i\infty} e^{st}g(s) ds$$

and to evaluate this integral requires a knowledge of complex variables, the theory of residues, and contour integration.

A function is said to be piecewise continuous on an interval if it has only a finite number of finite (or jump) discontinuities. A function  $f$  on  $0 < t < \infty$  is said to be of exponential growth at infinity if there exist constants  $M$  and  $\alpha$  such that  $|f(t)| \leq Me^{\alpha t}$  for sufficiently large  $t$ .

**Sufficient Conditions for the Existence of Laplace Transform** Suppose  $f$  is a function which is (1) piecewise continuous on every finite interval  $0 < t < T$ , (2) of exponential growth at infinity, and (3)  $\int_0^\delta |f(t)| dt$  exist (finite) for every finite  $\delta > 0$ . Then the Laplace transform of  $f$  exists for all complex numbers  $s$  with sufficiently large real part.

Note that condition 3 is automatically satisfied if  $f$  is assumed to be piecewise continuous on every finite interval  $0 \leq t < T$ . The function  $f(t) = t^{-1/2}$  is not piecewise continuous on  $0 \leq t \leq T$  but satisfies conditions 1 to 3.

Let  $\Lambda$  denote the class of all functions on  $0 < t < \infty$  which satisfy conditions 1 to 3.

**Example** Let  $f(t)$  be the Heaviside step function at  $t = t_0$ ; i.e.,  $f(t) = 0$  for  $t \leq t_0$ , and  $f(t) = 1$  for  $t > t_0$ . Then

$$L\{f(t)\} = \int_0^\infty e^{-st} dt = \lim_{T \rightarrow \infty} \int_0^T e^{-st} dt = \lim_{T \rightarrow \infty} \frac{1}{s} (e^{-st_0} - e^{-sT}) = \frac{e^{-st_0}}{s}$$

provided  $s > 0$ .

**Example** Let  $f(t) = e^{at}$ ,  $t \geq 0$ , where  $a$  is a real number. Then  $L\{e^{at}\} = \int_0^\infty e^{-(s-a)t} dt = 1/(s-a)$ , provided  $\text{Re } s > a$ .

**Properties of the Laplace Transform**

1. The Laplace transform is a linear operator:  $L\{af(t) + bg(t)\} = aL\{f(t)\} + bL\{g(t)\}$  for any constants  $a, b$  and any two functions  $f$  and  $g$  whose Laplace transforms exist.

2. The Laplace transform of a real-valued function is real for real  $s$ . If  $f(t)$  is a complex-valued function,  $f(t) = u(t) + iv(t)$ , where  $u$  and  $v$  are real, then  $L\{f(t)\} = L\{u(t)\} + iL\{v(t)\}$ . Thus  $L\{u(t)\}$  is the real part of  $L\{f(t)\}$ , and  $L\{v(t)\}$  is the imaginary part of  $L\{f(t)\}$ .

3. The Laplace transform of a function in the class  $\Lambda$  has derivatives of all orders, and  $L\{t^k f(t)\} = (-1)^k d^k F(s)/ds^k$ ,  $k = 1, 2, 3, \dots$

**Example**  $\int_0^\infty e^{-st} \sin at dt = \frac{a}{s^2 + a^2}$ ,  $s > 0$ . By property 3,  $\frac{2as}{(s^2 + a^2)^2} = \int_0^\infty e^{-st} t \sin at dt = L\{t \sin at\}$ .

**Example** By applying property 3 with  $f(t) = 1$  and using the preceding results, we obtain

$$L\{t^k\} = (-1)^k \frac{d^k}{ds^k} \left( \frac{1}{s} \right) = \frac{k!}{s^{k+1}}$$

provided  $\text{Re } s > 0$ ;  $k = 1, 2, \dots$ . Similarly, we obtain

$$L\{t^k e^{at}\} = (-1)^k \frac{d^k}{ds^k} \left( \frac{1}{s-a} \right) = \frac{k!}{(s-a)^{k+1}}$$

4. Frequency-shift property (or, equivalently, the transform of an exponentially modulated function). If  $F(s)$  is the Laplace transform of a function  $f(t)$  in the class  $\Lambda$ , then for any constant  $a$ ,  $L\{e^{at} f(t)\} = F(s-a)$ .

**Example**  $L\{te^{-at}\} = \frac{1}{(s+a)^2}$ ,  $s > 0$ .

5. Time-shift property. Let  $u(t-a)$  be the unit step function at  $t = a$ . Then  $L\{f(t-a)u(t-a)\} = e^{-as}F(s)$ .

6. Transform of a derivative. Let  $f$  be a differentiable function such that both  $f$  and  $f'$  belong to the class  $\Lambda$ . Then  $L\{f'(t)\} = sF(s) - f(0)$ .

7. Transform of a higher-order derivative. Let  $f$  be a function which has continuous derivatives up to order  $n$  on  $(0, \infty)$ , and suppose that  $f$  and its derivatives up to order  $n$  belong to the class  $\Lambda$ . Then  $L\{f^{(j)}(t)\} = s^j F(s) - s^{j-1} f(0) - s^{j-2} f'(0) - \dots - f^{(j-2)}(0) - f^{(j-1)}(0)$  for  $j = 1, 2, \dots, k$ .

**Example**  $L\{f''(t)\} = s^2 L\{f(t)\} - sf(0) - f'(0)$

$$L\{f'''(t)\} = s^3 L\{f(t)\} - s^2 f(0) - sf'(0) - f''(0)$$

**Example** Solve  $y'' + y = 2e^t$ ,  $y(0) = y'(0) = 2$ .  $L[y''] = -y'(0) - sy(0) + s^2 L[y] = -2 - 2s + s^2 L[y]$ . Thus

$$-2 - 2s + s^2 L[y] + L[y] = 2L\{e^t\} = \frac{2}{s-1}$$

$$L[y] = \frac{2s^2}{(s-1)(s^2+1)} = \frac{1}{s-1} + \frac{s}{s^2+1} + \frac{1}{s^2+1}$$

Hence  $y = e^t + \cos t + \sin t$ .

A short table (Table 3-2) of very common Laplace transforms and inverse transforms follows. The references include more detailed tables. NOTE:  $\Gamma(n+1) = \int_0^\infty x^n e^{-x} dx$  (gamma function);  $J_n(t)$  = Bessel function of the first kind of order  $n$ .

$$8. L\left[\int_a^t f(t) dt\right] = \frac{1}{s} L\{f(t)\} + \frac{1}{s} \int_a^0 f(t) dt$$

**TABLE 3-2 Laplace Transforms**

| $f(t)$                            | $g(s)$                        | $f(t)$                              | $g(s)$                         |
|-----------------------------------|-------------------------------|-------------------------------------|--------------------------------|
| 1                                 | $1/s$                         | $e^{-at}(1-at)$                     | $\frac{s}{(s+a)^2}$            |
| $t^n$ , ( $n+1$ integer)          | $\frac{n!}{s^{n+1}}$          | $\frac{t \sin at}{2a}$              | $\frac{s}{(s^2+a^2)^2}$        |
| $t^n$ , $n \neq$ integer          | $\frac{\Gamma(n+1)}{s^{n+1}}$ | $\frac{1}{2a^2} \sin at \sinh at$   | $\frac{s}{s^4+4a^4}$           |
| $\cos at$                         | $\frac{s}{s^2+a^2}$           | $\cos at \cosh at$                  | $\frac{s^2}{s^4+4a^4}$         |
| $\sin at$                         | $\frac{a}{s^2+a^2}$           | $\frac{1}{2a} (\sinh at + \sin at)$ | $\frac{s^2}{s^4-a^4}$          |
| $\cosh at$                        | $\frac{s}{s^2-a^2}$           | $\frac{1}{2} (\cosh at + \cos at)$  | $\frac{s^3}{s^4-a^4}$          |
| $\sinh at$                        | $\frac{a}{s^2-a^2}$           | $\frac{\sin at}{t}$                 | $\tan^{-1} \frac{a}{s}$        |
| $e^{-at}$                         | $\frac{1}{s+a}$               | $J_0(at)$                           | $\frac{1}{\sqrt{s^2+a^2}}$     |
| $e^{-bt} \cos at$                 | $\frac{s+b}{(s+b)^2+a^2}$     | $na^n \frac{J_n(at)}{t}$            | $(\sqrt{s^2+a^2}-s)^n (n > 0)$ |
| $e^{-bt} \sin at$                 | $\frac{a}{(s+b)^2+a^2}$       | $J_0(2\sqrt{at})$                   | $\frac{1}{s} e^{-a/s}$         |
| $\text{erfc} \frac{k}{2\sqrt{t}}$ | $\frac{1}{s} e^{-k\sqrt{s}}$  |                                     |                                |

**Example** Find  $f(t)$  if  $L\{f(t)\} = \frac{1}{s^2} \left[ \frac{1}{s^2-a^2} \right]$ .  $L\left[\frac{1}{a} \sinh at\right] = \frac{1}{s^2-a^2}$ .

Therefore  $f(t) = \int_0^t \left[ \int_0^t \frac{1}{a} \sinh at dt \right] dt = \frac{1}{a^2} \left[ \frac{\sinh at}{a} - t \right]$ .

9.  $L\left[\frac{f(t)}{t}\right] = \int_s^\infty g(s) ds$       $L\left[\frac{f(t)}{t^k}\right] = \underbrace{\int_s^\infty \dots \int_s^\infty}_{k \text{ integrals}} g(s)(ds)^k$

**Example**  $L\left[\frac{\sin at}{t}\right] = \int_s^\infty L\{\sin at\} ds = \int_s^\infty \frac{a ds}{s^2+a^2} = \cot^{-1} \frac{s}{a}$

10. The unit step function

$$u(t-a) = \begin{cases} 0 & t < a \\ 1 & t > a \end{cases} \quad L\{u(t-a)\} = e^{-as}/s$$

11. The unit impulse function is

$$\delta(a) = u'(t-a) = \begin{cases} \infty & \text{at } t = a \\ 0 & \text{elsewhere} \end{cases} \quad L\{u'(t-a)\} = e^{-as}$$

12.  $L^{-1}[e^{-as}g(s)] = f(t-a)u(t-a)$  (second shift theorem).

13. If  $f(t)$  is periodic of period  $b$ , i.e.,  $f(t+b) = f(t)$ , then

$$L\{f(t)\} = \left[ \frac{1}{1-e^{-bs}} \right] \int_0^b e^{-st} f(t) dt$$

**Example** The partial differential equations relating gas composition to position and time in a gas chromatograph are  $\partial y/\partial n + \partial x/\partial \theta = 0$ ,  $\partial y/\partial n = x - y$ , where  $x = mx'$ ,  $n = (k_C a P/C_m)h$ ,  $\theta = (mk_C a P/\rho_b)t$  and  $C_M$  = molar velocity,  $y$  = mole fraction of the component in the gas phase,  $\rho_b$  = bulk density,  $h$  = distance from the entrance,  $P$  = pressure,  $k_C$  = mass-transfer coefficient, and  $m$  = slope of the equilibrium line. These equations are equivalent to  $\partial^2 y/\partial n \partial \theta + \partial y/\partial n + \partial y/\partial \theta = 0$ , where the boundary conditions considered here are  $y(0, \theta) = 0$  and  $x(n, 0) = y(n, 0) + (\partial y/\partial n)(n, 0) = \delta(0)$  (see property 11). The problem is conveniently

solved by using the Laplace transform of  $y$  with respect to  $n$ ; write  $g(s, \theta) = \int_0^\infty e^{-sn} y(n, \theta) dn$ . Operating on the partial differential equation gives  $s(dg/d\theta) - (\partial y/\partial \theta)(0, \theta) + sg - y(0, \theta) + dg/d\theta = 0$  or  $(s+1)(dg/d\theta) + sg = (\partial y/\partial \theta)(0, \theta) + y(0, \theta) = 0$ . The second boundary condition gives  $g(s, 0) + sg(s, 0) - y(0, 0) = 1$  or  $g(s, 0) + sg(s, 0) = 1$  ( $L[\delta(0)] = 1$ ). A solution of the ordinary differential equation for  $g$  consistent with this second condition is

$$g(s, \theta) = \frac{1}{s+1} e^{-\theta/(s+1)}$$

Inversion of this transform gives the solution  $y(n, \theta) = e^{-(n+\theta)} I_0(2\sqrt{n\theta})$  where  $I_0$  = zero-order Bessel function of an imaginary argument. For large  $u$ ,  $I_n(u) \sim e^u/\sqrt{2\pi u}$ . Hence for large  $n$ ,

$$y(n, \theta) \sim \frac{\exp[-(\sqrt{\theta} - \sqrt{n})^2]}{2\pi^{1/2}(n\theta)^{1/4}}$$

or for sufficiently large  $n$ , the peak concentration occurs near  $\theta = n$ .

Other applications of Laplace transforms are given under "Difference Equations."

**CONVOLUTION INTEGRAL**

The convolution integral (faltung) of two functions  $f(t)$ ,  $r(t)$  is  $x(t) = f(t) \circ r(t) = \int_0^t f(\tau)r(t-\tau) d\tau$ .

**Example**  $t^\circ \sin t = \int_0^t \tau \sin(t-\tau) d\tau = t - \sin t$

$$L[f(t)]L[h(t)] = L[f(t) \circ h(t)]$$

**z-TRANSFORM**

See Ogunnaike, Babatunde A., and W. Harmon Ray, *Process Dynamics, Modeling, and Control*, Oxford University Press (1994); Seborg, D., T. F. Edgar, and D. A. Mellichamp, *Process Dynamics and Control*, 2d ed., Wiley, New York (2003). The  $z$ -transform is useful when data is available at only discrete points. Let

$$f^\circ(t) = f(t_k)$$

be the value of  $f$  at the sample points

$$t_k = k \Delta t, \quad k = 0, 1, 2, \dots$$

Then the function  $f^\circ(t)$  is

$$f^\circ(t) = \sum_{k=0}^\infty f(t_k) \delta(t - t_k)$$

Take the Laplace transform of this.

$$g^\circ(s) = L[f^\circ(t)] = \sum_{k=0}^\infty f(t_k) e^{-st_k} = \sum_{k=0}^\infty f(t_k) e^{-s\Delta t k}$$

For convenience, replace  $e^{s\Delta t}$  by  $z$  and call  $g^\circ(z)$  the  $z$ -transform of  $f^\circ(t)$ .

$$g^\circ(z) = \sum_{k=0}^\infty f(t_k) z^{-k}$$

The  $z$ -transform is used in process control when the signals are at intervals of  $\Delta t$ . A brief table (Table 3-3) is provided here.

The  $z$ -transform can also be used to solve difference equations, just like the Laplace transform can be used to solve differential equations.

**Example** The difference equation for  $y(k)$  is

$$y(k) + a_1 y(k-1) + a_2 y(k-2) = b_1 u(k)$$

Take the  $z$ -transform

$$(1 + a_1 z^{-1} + a_2 z^{-2}) y^\circ(z) = b_1 u^\circ(z)$$

Then

$$y^\circ(z) = \frac{u^\circ(z)}{1 + a_1 z^{-1} + a_2 z^{-2}}$$

The inverse transform must be found, usually from a table of inverse transforms.

**FOURIER TRANSFORM**

**REFERENCES:** Bateman, H., *Tables of Integral Transforms*, vol. I, McGraw-Hill, New York (1954); Varma, A., and M. Morbidelli, *Mathematical Methods in Chemical Engineering*, Oxford, New York (1997).

**TABLE 3-3 z-Transforms**

| $f(k)$  | $g^\circ(z)$  |
|---|---|
| 1(k)  | $\frac{1}{1-z^{-1}}$  |
| $k \Delta t$                                    | $\frac{\Delta t z^{-1}}{(1-z^{-1})^2}$  |
| $(k \Delta t)^{n-1}$                            | $\lim_{a \rightarrow 0} (-1)^{n-1} \frac{\partial^{n-1}}{\partial a^{n-1}} \left( \frac{1}{1 - e^{-a\Delta t} z^{-1}} \right)$  |
| $\sin a k \Delta t$                             | $\frac{z^{-1} \sin a \Delta t}{(1 - 2z^{-1} \cos a \Delta t + z^{-2})}$   |
| $\cos a k \Delta t$                             | $\frac{1 - z^{-1} \cos a \Delta t}{(1 - 2z^{-1} \cos a \Delta t + z^{-2})}$   |
| $e^{-ak\Delta t}$                               | $\frac{1}{1 - e^{-a\Delta t} z^{-1}}$   |
| $e^{-bk\Delta t} \cos a k \Delta t$             | $\frac{1 - z^{-1} e^{-b\Delta t} \cos a \Delta t}{1 - 2z^{-1} e^{-b\Delta t} \cos a \Delta t + z^{-2} e^{-2b\Delta t}}$         |
| $\frac{1}{b} e^{-bk\Delta t} \sin a k \Delta t$ | $\frac{1}{b} \frac{z^{-1} e^{-b\Delta t} \sin a \Delta t}{1 - 2z^{-1} e^{-b\Delta t} \cos a \Delta t + z^{-2} e^{-2b\Delta t}}$ |

The Fourier transform is given by

$$F[f(t)] = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^\infty f(t) e^{-ist} dt = g(s)$$

and its inverse by

$$F^{-1}[g(s)] = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^\infty g(s) e^{ist} dt = f(t)$$

In brief, the condition for the Fourier transform to exist is that  $\int_{-\infty}^\infty |f(t)| dt < \infty$ , although certain functions may have a Fourier transform even if this is violated.

**Example** The function  $f(t) = \begin{cases} 1 - a \leq t \leq a \\ 0 \text{ elsewhere} \end{cases}$  has  $F[f(t)] = \int_{-a}^a e^{-ist} dt =$

$$\int_0^a e^{ist} dt + \int_0^a e^{-ist} dt = 2 \int_0^a \cos st dt = \frac{2 \sin sa}{s}$$

**Properties of the Fourier Transform** Let  $F[f(t)] = g(s)$ ;  $F^{-1}[g(s)] = f(t)$ .

- $F[f^{(n)}(t)] = (is)^n F[f(t)]$ .
- $F[af(t) + bh(t)] = aF[f(t)] + bF[h(t)]$ .
- $F[f(-t)] = g(-s)$ .
- $F[f(at)] = \frac{1}{a} g\left(\frac{s}{a}\right), a > 0$ .
- $F[e^{-iat} f(t)] = g(s + w)$ .
- $F[f(t + t_1)] = e^{ist_1} g(s)$ .
- $F[f(t)] = G(is) + G(-is)$  if  $f(t) = f(-t)$  (f even)  
 $F[f(t)] = G(is) - G(-is)$  if  $f(t) = -f(-t)$  (f odd)

where  $G(s) = L[f(t)]$ . This result allows the use of the Laplace-transform tables to obtain the Fourier transforms.

**Example** Find  $F[e^{-at|t|}]$  by property 7.  $e^{-at|t|}$  is even. So  $L[e^{-at}] = 1/(s+a)$ . Therefore,  $F[e^{-at|t|}] = 1/(is+a) + 1/(-is+a) = 2a/(s^2 + a^2)$ .

**FOURIER COSINE TRANSFORM**

The Fourier cosine transform is given by

$$F_c[f(t)] = g(s) = \sqrt{\frac{2}{\pi}} \int_0^\infty f(t) \cos st dt$$

and its inverse by

$$F_c^{-1}[g(s)] = f(t) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} g(s) \cos st \, ds$$

The Fourier sine transform  $F_s$  is obtainable by replacing the cosine by the sine in these integrals. They can be used to solve linear differential equations; see the transform references.

### MATRIX ALGEBRA

**Matrices** A rectangular array of  $mn$  quantities, arranged in  $m$  rows and  $n$  columns

$$A = (a_{ij}) = \begin{bmatrix} a_{11} & \cdots & a_{1n} \\ a_{21} & \cdots & a_{2n} \\ \vdots & & \vdots \\ a_{m1} & \cdots & a_{mn} \end{bmatrix}$$

is called a matrix. The elements  $a_{ij}$  may be real or complex. The notation  $a_{ij}$  means the element in the  $i$ th row and  $j$ th column,  $i$  is called the row index,  $j$  the column index. If  $m = n$  the matrix is said to be square and of order  $n$ . A matrix, even if it is square, does not have a numerical value, as a determinant does. However, if the matrix  $A$  is square, a determinant can be formed which has the same elements as the matrix  $A$ . This is called the determinant of the matrix and is written  $\det(A)$  or  $|A|$ . If  $A$  is square and  $\det(A) \neq 0$ ,  $A$  is said to be nonsingular; if  $\det(A) = 0$ ,  $A$  is said to be singular. A matrix  $A$  has rank  $r$  if and only if it has a nonvanishing determinant of order  $r$  and no nonvanishing determinant of order  $> r$ .

**Equality of Matrices** Let  $A = (a_{ij})$ ,  $B = (b_{ij})$ . Two matrices  $A$  and  $B$  are equal ( $=$ ) if and only if they are identical; that is, they have the same number of rows and the same number of columns and equal corresponding elements ( $a_{ij} = b_{ij}$  for all  $i$  and  $j$ ).

**Addition and Subtraction** The operations of addition (+) and subtraction (-) of two or more matrices are possible if and only if they have the same number of rows and columns. Thus  $A \pm B = (a_{ij} \pm b_{ij})$ ; i.e., addition and subtraction are of corresponding elements.

**Transposition** The matrix obtained from  $A$  by interchanging the rows and columns of  $A$  is called the transpose of  $A$ , written  $A^T$  or  $A^T$ .

**Example**  $A = \begin{bmatrix} 1 & 3 & 4 \\ 2 & 1 & 6 \end{bmatrix}$ ,  $A^T = \begin{bmatrix} 1 & 2 \\ 3 & 1 \\ 4 & 6 \end{bmatrix}$

Note that  $(A^T)^T = A$ .

**Multiplication** Let  $A = (a_{ij})$ ,  $i = 1, \dots, m_1$ ;  $j = 1, \dots, m_2$ .  $B = (b_{ij})$ ,  $i = 1, \dots, n_1$ ,  $j = 1, \dots, n_2$ . The product  $AB$  is defined if and only if the number of columns of  $A$  ( $m_2$ ) equals the number of rows of  $B$  ( $n_1$ ), i.e.,  $n_1 = m_2$ . For two such matrices the product  $P = AB$  is defined by summing the element by element products of a row of  $A$  by a column of  $B$ . This is the row by column rule. Thus

$$p_{ij} = \sum_{k=1}^{n_1} a_{ik} b_{kj}$$

The resulting matrix has  $m_1$  rows and  $n_2$  columns.

**Example**  $\begin{bmatrix} 3 & 2 \\ 1 & 1 \\ 5 & 4 \end{bmatrix} \begin{bmatrix} 0 & 1 & 5 & 6 \\ -2 & 0 & 1 & 3 \end{bmatrix} = \begin{bmatrix} -4 & 3 & 17 & 24 \\ -2 & 1 & 6 & 9 \\ -8 & 5 & 29 & 42 \end{bmatrix}$
